The pelts of skins used for felting purposes, after the fur is taken off them, are of little value. They are generally sent to the west of England, and sold for the purpose of making a fine kind of glue, much used in the manufacture of fine cloth. Their present value is only about eighteen shillings per hundredweight.

On the Manufacture of Furs for Ornament and Clothing.

It was not till the later ages that the furs of beasts became an article of luxury. The more refined nations of ancient times never made use of them; those alone whom the former stigmatized as barbarians were clothed in the skins of animals. Strabo describes the Indians as covered with the skins of lions, panthers, and bears; and Seneca, the Scythians as clothed with the skins of foxes and the lesser quadrupeds. Virgil exhibits a picture of the savage Hyperboreans, similar to that which our late circumnavigators have witnessed in the clothing of the wild Americans, unseen before by any polished people. Most part of Europe was at this time in similar circumstances. Cæsar might be as much amazed with the skin-dressed heroes of Britain, as our celebrated Cook was at those of his newly-discovered regions. What time has done to us, time, under humane conquerors, may effect for them. Civilization may take place; and those spoils of animals, which are at present essential for clothing, become the mere objects of ornament and luxury.

It does not appear that the ancient Greeks or Romans ever made use of furs. It originated in those regions where they most abounded, and where the severity of the climate required that species of clothing. At first it consisted of the skins only, almost in the state in which they were torn from the body of the beast; but as soon as civilization took place, and manufactures were introduced, furs became the lining of the dress, and often the elegant facing of the robes. It is probable that the northern conquerors introduced the fashion into Europe. We find, that about the year 522, when Totila, king of the Visigoths, reigned in Italy, the Suethons, a people of modern Sweden, found means, by help of the commerce of numberless intervening people, to transmit, for the use of the Romans, the precious skins of the sable. As luxury advanced, furs, even of the most valuable species, were used by princes as linings for their tents. Thus, Marco Polo, in 1252, found those of the Cham of Tartary lined with ermines and sables, the last of which he calls *zibelines* and *zambolines*. He says that these and other precious furs were brought from countries far north; from the *land of darkness*, and regions almost inaccessible by reason of morasses and ice. The Welsh set a high value on furs as early as the time of Howel Dda, who began his reign about 940. In the next age furs became the fashionable magnificence of Europe. When Godfrey of Boulogne and his followers appeared before the Emperor Alexis Comnenus, on their way to the Holy Land, he was struck with the richness of their dresses. How different was the advance of luxury in France from the time of their great monarch Charlemagne, who contented himself with the plain fur of the otter. Our Henry I. wore furs, yet in his distress was obliged to change them for warm Welsh flannel. But in the year 1337 the luxury had got to such a head that Edward III. enacted, that all persons who could not spend a hundred pounds a year should absolutely be prohibited the use of this species of finery. These, from their great expense, must have been foreign furs, obtained from the Italian states, the traffic of which was at this period boundless. How strange is the revolution in the fur trade. The north of Asia at that time supplied us with every valuable kind; at present we send, by means of the possessions of Hudson's Bay, furs to an immense amount, even to Turkey and to China.

The business of preparing skins for articles of dress is much more simple, and employs a great deal fewer hands, than the trade of manufacturing furs for felting purposes. The first thing to be attended to by those who follow the former occupation is to examine the skin as to the manner in which it has been dried. If it has experienced the slightest degree of putrefaction, it will never be of any use for the purpose of dressing as fur. Great attention is, therefore, paid by the hunters, and those who are engaged in bringing the furs to market, as to the drying of the skins, and the proper manner of packing and preserving them when they are dried. Exposure to the air is the best method of drying a skin after it is taken off the animal, or hanging it up in a dry and cool room where there is no fire. If skins be once thoroughly dried in this manner, they may be preserved for a great length of time, and transported to any distance without injury.

In the dressing of furs for clothing or ornament two things are necessary; to remove the fat or grease from the pelt; and to extract the oiliness from the fur itself, and impart to it a bright and shining appearance. In the accomplishment of these two things the whole art consists. The clearing of the pelt is effected by applying a composition of bran, alum, and salt to it; and the cleansing of the fur by a mixture of soda and fine soap. The skins, after having undergone these processes, are washed with cold water, and dried gradually in the air.

After the skins are prepared in this manner, the next thing is to cut them to advantage. In almost all the articles of the fur kind used as clothing, we find them made up of small and detached pieces of skin, to give these articles a uniform appearance as to the length and colour of the fur. Hence it becomes a point of great importance to a furrier not to have his skins cut to a disadvantage, but to make the most of every part of them.

Very few of the skins used for felting purposes are manufactured for dress. The principal of the latter kind are the grey, silver, and black fox, the ermine, the sable, the chinchilla, the fitchet, the bear, the marten, the mink, the lynx, and the wolf.

FURBISHER, a person who furbishes, polishes, or cleans arms, as guns, swords, pistols, &c. which is chiefly performed with emery.

FURCA, in *Antiquity*, a piece of timber resembling a fork, which was used by the Romans as an instrument of punishment.

There were three methods of punishing by the furca. The first, which was only ignominious, consisted in a master, for small offences, forcing a servant to carry a furca on his shoulders through the city. In the second, which was penal, the party was led round the circus, or other place, with the furca upon his neck, and whipped all the way. The third was capital. In this instance the malefactor having his head fastened on the furca, was whipped to death.

FURCHÉ, in *Heraldry*, a cross forked at the ends.

FURETIERE, ANTHONY, an eminent French philological writer, was born at Paris in the year 1620. He first studied law, and was a counsellor of parliament; but he abandoned these pursuits, adopted the ecclesiastical profession, and became abbot of Chalivoi and Cluines. He now composed various works in prose and verse, by which he greatly distinguished himself and extended his reputation. He was elected a member of the French Academy, the meetings of which learned society he assiduously attended; but having engaged in the compilation of a dictionary of the French language, at a time when his brother academicians collectively were employed in a similar undertaking, his conduct was deemed disrespectful to his colleagues; and a specimen of his work having been published in 1684, he was in the year following expelled the academy. He retaliated by publishing a *Factum* in his own defence, which, on account of its keen satire and invective, served to render his exclusion from that learned body permanent. He died in the year 1688. His dictionary was published in 1690 in two vols. folio. It was republished with improvements by Basnage de Beauval in 1701, in three vols. It afterwards received a further enlargement, and served as the basis of the *Dictionnaire de Trevoux*, of which an edition appeared in 1771, in eight vols. folio. Furetière's other works were Five Satires in verse, Gospel Parables in prose, Le Roman Bourgeois, &c. There is also a collection of anecdotes by him entitled *Furetieriana*. (R. R. R.)

FURIES, in pagan antiquity, were goddesses whose office it was to punish the guilty after death. They were three in number, Alecto, Megæra, and Tisiphone, and were described as having snakes instead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish, the guilty. They were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose that Tisiphone punished the crimes which sprang from hatred or anger; Megæra those from envy; and Alecto those arising from an insatiable pursuit after riches and pleasure.

FURLING, in naval affairs, signifies the operation of wrapping up and binding any sail close to the yard.

FURLONG, an English long measure, equal to one eighth of a mile, or 660 feet.

FURLOUGH, in the military language, is a license granted by an officer to a soldier to be absent from his duty for a limited time.

FURNACE,

A GENERAL name for those contrivances used in the arts and in chemistry, by which an extraordinary degree of heat is generated, much more intense than what obtains in our ordinary fire-places. These are of very extensive use, particularly where metals and minerals are the subjects of manufacture or of examination, such substances requiring a very powerful heat for their reduction, calcination, or fusion. Hence the various kinds of furnaces which occur in the manufacture of iron, steel, brass, copper, zinc, &c. in smelting, casting, and forging the metal, and in numerous other processes connected with the formation of it. In other cases, such as glass-works, potteries, and various others, it is in general not so much a very intense heat that is wanted, as a steady temperature, and the fire of such magnitude as will keep a large body of material in fusion, and at a very equable state for working. Another large and extensive class of furnaces, and one which is becoming every day of more and more importance, is that applied to the generation of steam in the boilers of steam-engines; and here also it is not so much an intense heat which is necessary, as a very large quantity for a rapid production of the elastic fluid. The construction of furnaces therefore forms an interesting and very important branch of practical mechanics. We shall endeavour at present to explain the general principles of their construction, and describe a few of those most generally in use; and further information will be found in treating of the different arts, manufactures, and processes where the furnaces are chiefly employed.

In regard to the general principles on which the operation of furnaces depends, the exact nature of the process of combustion is, we believe, hardly yet settled among chemical philosophers; and experiments are wanting to determine many points which might be practically useful. It was thought, for example, by Sir Humphry Davy, that by a vivid and rapid combustion of our fuel, a much greater quantity of heat would be generated than by a slow and languid action; and this theory, were it consistent with fact, would often be of great importance where economy of fuel is the object. Be this, however, as it may, it is certain that, in our ordinary furnaces, whatever be the fuel, the grand supporter of combustion is the atmospheric air, or rather the oxygen, which forms one of its constituent parts; and it is the combination of this aerial element with the solid mass of the combustible material in the furnace, which somehow or other, not well understood, produces all the heat that we obtain. To provide, therefore, a supply of this vital principle is the first object in the construction of every furnace. It appears, from some experiments on the products of combustion made by our celebrated chemist Dr Thomson of Glasgow, that for every pound weight of good caking coal consumed in a furnace, there will be required at least 150 cubic feet of common air; and adding fifty more for what cannot be rendered effective, we may allow at least 200 cubic feet to each pound of coal; and this may give us some idea of the vast quantity of air which must be required for many of the large furnaces and fires which are frequently used. In many of the furnaces, for instance, for the boilers of our steam-vessels, the consumpt of coal is more than twenty cwt. each hour; and by the above calculation this will require 7400 cubic feet of air per minute.

Draught by chimney.

It may seem at first no easy matter to supply so large a stream, and to make it pass regularly through the fire; yet this is done in the simplest manner, by means of the chimney, on the principle of the ascensional power of heated air; and few examples occur in practical mechanics of so simple, beautiful, and highly useful an application of a general principle. Air, like every other substance, is expanded by heat, and this in a remarkable degree, owing to the feeble aggregation of its elementary parts. With every degree of Fahrenheit, from the temperature of freezing to that of boiling mercury, or 680°, it expands the 488th part of its bulk. This is according to the accurate experiments of Messrs Petit and Dulong; and these philosophers also found the important law to obtain exactly within the above range of the thermometer, that equal increments of heat produced equal increments of expansion. Hence with a heat of 488°, which is far surpassed in our fires, the volume of the air is doubled; but with every such expansion the air becomes in proportion specifically lighter, and ascends by its buoyancy through the colder and of course denser medium around it. The fire therefore heating the air above it, this ascends, and the chimney forming a tube or perpendicular shaft, either directly above the fire-place, or in communication with it, the heated air fills it, and forms a rarefied column standing in the midst of the ordinary medium. The external columns, therefore, pressing on all sides into the partial vacuity, must rush in below where there is a free communication through the fire: thus a constant draught of air sets in towards the fire and up the chimney; and by this means the combustion in the furnace is kept up. It is exactly what takes place on a great scale over the globe itself, by the sun heating excessively the regions under the line; and this causing everywhere a current of heated air upwards, draws continually a current of cold air from the regions on each side of the tropics; and it is this which produces the phenomenon of the trade-winds, the opposite currents coming into collision under the equator, and destroying each other's effect as to north or south, while the rotation of the earth gives the whole an apparent motion nearly due east. The chimney then is the most essential part of every furnace, and its use is not only to create a draught of heated air, but to receive and discharge the smoke and other aerial products which arise from the combustion. In ordinary fire-places, where only a very moderate degree of heat is wanted to heat our apartments comfortably, the chimney is left open below, immediately above the fire-place, for the convenience of getting fuel or cooking utensils put on. In that case only a very small portion of the air which ascends up the chimney passes through the fire, namely, that which ascends from under the grating, and perhaps a little in the front. The greater proportion ascends above the fire-place, and this mixing with the heated air, cools it, and moderates the draught, which would otherwise become too great. In furnaces, however, where all the heat is required which can be produced, a different arrangement becomes necessary. The fire-place in these must be closed on all sides, and every access to the air excluded, excepting below, where the fuel rests on an open grating, consisting of iron bars laid parallel to each other, and at such distances apart as will retain the fuel, while the air is admitted through them, and the ashes and other refuse drop down into the ash-pit below.

Essential parts.

Hence arises the same general construction in every furnace; and, however they may vary in particular forms and dimensions, each contains a *fire-place, grating, ash-pit,* and *chimney.* It is very essential, particularly where an intense temperature is wanted, that the fire-place should be surrounded with substances of a very slow conducting power for heat, otherwise this would be soon dissipated in the surrounding atmosphere, and no high degree of temperature attained. Clay is found very useful for this purpose in small furnaces intended for experiments; and the effect is most strikingly exhibited if we try the action of a fire-place of sheet iron: the heat is extremely feeble, and is observed dissipating itself on all sides; but if we line it with an inch thickness of clay or pounded charcoal, a very intense heat may then be generated. In large furnaces there is no material so useful for this purpose as brick, which is not only a slow conductor, but can be made to withstand very intense heats.

Grating.

The magnitude of the fire must evidently be determined by the size of the grating; for, however large the fire-place be made, or great the quantity of fuel in it, unless the grating is such as will admit a sufficiency of air, the combustion will not proceed. In large fires, therefore, intended to generate a great quantity of heat, such as those for steam-engine boilers, the grates must be made large in proportion. In fires, again, where it is not so much quantity as an intense temperature, the grate may be quite small, as the temperature will depend chiefly on the power of the draught. Most of the operations of the brass-founder, and of gold and silver-smiths, are performed with furnaces of which the grate does not exceed two feet in area. It may be reckoned generally, that for every ten pounds of coal consumed in an hour, there should be a square foot of area in the grating. The spaces between the bars should be about three eighths or half an inch. The bars themselves should be loose, and made to rest on two cross bars, one at each end, so that they can be taken out and renewed at pleasure. In that case they are made about an inch thick, and with a swell in the middle for greater strength. They are seldom made more than two feet or two and a half feet in length, one or more of such lengths being used if required.

Power of the draught.

But the grating itself, though it will admit it, will not determine any air to enter and pass through the fire. This is done by the draught in the chimney; and according as this is more or less powerful, the fire will burn with greater or less force. It is of the first importance, therefore, to determine what are the circumstances in the form and dimensions of the chimney on which the effect of this draught depends, and by which it may be regulated to our purposes. It is evident, in the first place, that the warmer the air is in the chimney, the greater will be its buoyant force, and the more powerful, therefore, the draught upwards. Every means, therefore, should be taken to preserve the heat in the chimney; and hence the great advantage in dwelling-houses of conducting the vents as much as possible through the interior walls, which are not exposed to the cooling effects of the atmosphere, or of wind and rain, and also carrying them up in a mass together, by which each protects the other from the cold; secondly, the interior of the chimney should be as straight, smooth, and regular as possible, that the current of air may traverse it with the least possible degree of impediment. There should be no projections, nor any sudden inequalities in width, which are sure to create eddies, and obstruct the progress of the air. Hence even the cylindrical form of a chimney will be found to improve the draught, because it presents a larger area than a square in proportion to its circumference, and therefore presents less obstruction. A decided improvement has lately been introduced in the construction of domestic chimneys, by the use of cylindrical cans of fire-brick, about a foot long, and built in, one above the other, to the top of the chimney. These are glazed inside, and present on the whole a very smooth and equal bore for the heated air. The cylindrical form of a chimney also presents externally less extent of cooling surface than the square. Still there are facilities of construction in the square form which give them an advantage. But whether circular or square, as the air becomes necessarily rather cooler at the top of the chimney than the bottom, and therefore denser, hence the chimney should have a slight degree of taper in proportion to this.

Height of chimney.

But of all the circumstances affecting the draught of furnaces, that which has the most powerful influence is the height of the chimney. The reason of this will be evident, if we consider that the mechanical force producing the draught is nothing else than the superior weight of the external air over that within the chimney. The latter forms a column expanded by heat, and having thus lost part of the air which it would have contained had it been at the same temperature with the external air. The external column, therefore, presses on the internal with a force exactly equal to this difference, and which is evidently proportional to the height of the chimney. For suppose we had a chimney fifteen feet high, and the air within it heated to 488°, then one half of the air originally in the chimney will be expelled. The column of fifteen feet would now, if the tube were extended, occupy thirty feet. This fifteen feet, therefore, of the expanded air, being taken out of the scale of the internal column, it is evident that the external air will now act with a preponderating force exactly equal, or with such a pressure as will be due to a column of the expanded air fifteen feet high, which is just equal to a column of the ordinary air seven and a half feet high. But suppose the chimney is thirty feet high under the same circumstances, then the column of expanded air expelled by the heat will be thirty feet high, and the preponderating column of ordinary air fifteen feet, just double of the former, in proportion to the double altitude, and so of every other height; and hence we deduce an important rule, that the *height* of the preponderating part of the column of air, by which the draught is produced in the chimney, is in every case *proportional to the height of the chimney itself;* and it is easy, from what has been stated, to form a calculation of this height in every case. Let H be the height of the chimney, n the number of degrees by which the internal air is heated beyond the external, taking of course the average heat of the top and bottom of the chimney, or any other rule for giving a true average from top to bottom, then $H + \frac{nH}{488}$ will be the height of the internal column when expanded by the heat, and $\frac{nH}{488}$ the height of the preponderating part of the external column, supposing it to have the density of the internal. But suppose it to be of the ordinary density, it will be $\frac{nH}{488 + n}$.

These principles then being established, it is easy now to calculate the velocity with which the external air will rush into the chimney; and this is the most important point to arrive at, as it is this which must determine the rate of supply, and whether it will be more or less than what is calculated on. This velocity, then, or V, according to the well-known formula, will be each second eight times the square root of the height of the preponderating part of the column; and as this height is proportional to that of the chimney itself, hence the rule that *the velocity is proportional to the square root of the height of the chimney.* Taking then the above expression for the height of the preponderating part of the column, we have the velocity of the external air rushing into the chimney $V = 8\sqrt{\frac{nH}{480 + n}}$. But in passing along the sides of the chimney, the air, particularly with great velocities, encounters considerable obstruction; and for this, and for what may arise from inequalities or other causes, we may allow 6 instead of 8 for the co-efficient in the above formula; this gives $V = 6\sqrt{\frac{nH}{480 + n}}$. The air is also greatly obstructed at the grating, and in passing through the interstices of the fuel; but this is supposed to be allowed for by giving the grating an enlarged capacity on this account, so that it may have the same facility in passing through the fire as it has in the chimney. This source of obstruction therefore need not be taken into account.

The above simple formula will be found to agree very nearly with facts; and we have been thus particular in deducing it from well-known and established principles, as rules and calculations have been given on this subject by different authors, the results of which differ considerably from each other. In cases of this nature, it is really superfluous to enter into all the refinements of calculation; there are in actual practice so many anomalies and deranging circumstances, that the only rules of any utility are those which embody simply, but with accuracy, the leading principles involved in the action; more complicated formulæ, even though rigidly exact, instead of guiding, serve often rather to deter the practical engineer from any calculation at all. In an ingenious paper on this subject, by an eminent mathematician, in the *Quarterly Journal of Science,* rigorous formulæ are given for the above calculations; but they are more complex, and the accuracy of some parts may be doubted. The rarefaction of the air by heat, for example, is calculated by a rule which makes it, for 1500°, to be expanded upwards of twenty times its natural volume; whereas, by Petit and Du Long's experiments, it would not exceed $4\frac{1}{4}$ times. Let us now take an example. Suppose we have a chimney thirty feet in height, and the average temperature of the air in it 300° above the external atmosphere, What will be the velocity with which the external air will enter the chimney? Here $H = 30$ $n = 300$, therefore $V = 6\sqrt{\frac{9000}{788}}$, or about 20 feet per second. Hence a chimney at this height, and one foot square, ought to supply 1200 feet per minute; and, from what we have seen, this would be sufficient to consume six pounds of coal per hour; and by enlarging the area of the chimney it would be adapted to a larger fire. But suppose it is raised to 100 feet, the velocity being in every case as the square root of the height, this would give the ratio of $5\frac{1}{2}$ to 10, or 37 feet per second, and a supply, with a one-foot chimney, of 2220 feet a minute. This shows how slowly the effect of raising the chimney proceeds. It requires the height to be raised four times to double the effect, and nine times to triple it; and this explains the great effect, comparatively, which is often produced by chimneys of moderate height judiciously constructed.

In this manner it is easy to calculate the effect of different heights and areas of chimneys, and proportion our dimensions to the nature of the fire to be used. In the above calculations it must be kept in view that the velocity referred to is always the velocity of the external air entering under the fire. The velocity in the chimney itself may be often very different; and by not attending to this distinction, serious mistakes may be committed. The formula for this velocity is simpler, being $V = 6\sqrt{\frac{nH}{480}}$, and in the above case it is twenty-five in place of twenty, and the supply 1500 feet in place of 1200.

Blast-furnace.

In the smelting of iron, and other uses, where a more intense temperature is required than can be produced by the natural draught of a chimney, it is necessary to resort to artificial means for increasing the effect; and this gives rise to the *blast-furnace,* where the draught is produced by the action of bellows or blowing cylinders throwing by mechanical force a violent current of air into the fire. The same object has recently been attained in a very convenient manner by means of fanners, which was originally proposed, we believe, by Desaguliers in the *Philosophical Transactions,* under the name of the centrifugal wheel, for the purpose of ventilating hospitals, ships, &c., and was a few years ago revived and successfully adapted to the blast-furnace by Messrs Carmichael, engineers, Dundee, and is now employed, not only for smelting, but instead of the bellows in the smith's forge, eight or ten forges being in some manufactories all supplied from one fan-wheel.

Description of furnaces.

We shall now describe a few of the furnaces most generally in use. The first is the common air-furnace used chiefly for melting the metals. In this, the metal being placed in a crucible, is set in the heart of the fire, and the heat is communicated directly from the materials in combustion, of which charcoal or coke is the most powerful. The draft is produced by a chimney of proper capacity and height, and the heat generated is retained by a building of brick. The most perfect form of air-furnace of this description would be to have the chimney ascending right above the fire-grate, and to be nearly of the same capacity. In that case, the draft would operate with the most powerful effect. But in practice it is found more convenient to have the use of the space immediately above the fire-place for getting in and out the crucibles and the metal. The chimney is therefore set to a side, and the draft directed into it by a sloping vent, or even by a level flue, the height of the chimney making up for any deficiency in the direct course of the heated air. Plate CCLI. fig. 1, shows a furnace of this description, being a section and side elevation. A shows the fire-place or body of the furnace, with a smelting-pot or crucible on its stand. The stand is often omitted, but is useful in raising the crucible above the grate, so as to allow the bottom of it to receive the full heat of the fire. B is the sloping flue, terminating in the chimney C, and D is the cover or door for closing the opening when the crucible is set. The angle E at the top of the inclined vent serves for setting a crucible to heat when necessary. *a* is the grate, and F the ash-pit opening through the outer wall, or into a cellar below, which serves to prevent the cold air rushing in from injuring the workmen. *d* is the damper. Fig. 2 is a plan of the same furnace, showing the furnace-bars, &c.

Common air-furnace.

Fig. 3 is a section of another air-furnace, with a horizontal flue above the fire-place. Fig. 4 is a section of a brass-founder's melting-furnace, which is found to answer the purpose extremely well. The body of the furnace is circular, composed of three courses of bricks formed to the arch, as shown in the plan, fig. 5. At the top and bottom, and at the two intermediate joints of the bricks, the whole is bound with hoops like a barrel, forming a very strong and durable construction. The flue is horizontal, and of small capacity compared with the fire-place. Above all there is an iron plate, with a flanch in front, holding the brick-work together, and an iron cover, *a*, shutting the opening. A is the ash-pit; B the pavement on the floor of the workshop.

Reverberatory furnaces.

The next sort of air-furnace is what is termed the reverberatory furnace. In this the metal is acted on, not by the heat generated among the combustible materials in the heart of the fire, but by the action of the flame and the heated air striking against it as it ascends up the chimney. The fuel best suited for this furnace, therefore, is coal, not coke; and for the purpose of directing the current, the space above the fire-place is arched over, and a horizontal or slightly descending flue is extended from this space to about three or four times the length of the fire-place, until it terminates in the bottom of the chimney. In this flue the metal is placed, and the flame and heated air striking against the top of the arch above the fire-place, is from thence reflected with full force against the metal, and from this sort of reverberation which takes place the furnace takes its name. From this action, and from the flame heating the interior of the chimney, the effect of this furnace is very powerful; and it is most extensively used in the iron manufacture.

At Plate CCLI. figs. 6, 7, and 8, are represented a plan and sections of one of these reverberatory furnaces. A is the fire-place with the arch above; B the descending flue; C the chimney; *d* the damper; E the ash-pit; F is an opening for introducing the metal or other substance to be acted on, which is laid on the inclined hearth at B, where the flame, reverberating from the top of the arch, strikes with full force. If the substance is intended to be melted, it runs down, and can be taken out at the opening G.

At fig. 9 is a view of another reverberatory furnace, contrived by Dr Black. The hearth or bottom of the flue B here is horizontal. Immediately above the fire-place there is an arched cover, H, of iron, from the top of which an arch of brick-work is extended all the way to the chimney, in which the flame reverberates down upon the hearth. There is only one opening, F, for the introduction of the metal. This furnace may be used with advantage for roasting various substances, such as the ores of metals, for the purpose of expelling their volatile matter. It may also be employed for the cupellation of metals, the door, F, being a little opened for admitting atmospheric air.

Furnace by Mushet.

A furnace of great power was constructed and employed by Mr Mushet, in his numerous and valuable experiments on iron and steel, and was found very convenient for such operations. It is represented at Plate CCLII. figs. 1, 2, 3. Fig. 1 is the section of an assay or melting and annealing furnace, and also a small reverberatory furnace for fusing in very high heats with the flame of pit-coal.

The assay-furnace is cased in cast iron, with a flanch projecting inward the breadth of a brick, and about half an inch more, which serves instead of bearers for the bars (see fig. 2 at D). Upon this flanch the brick-work is reared. It ought to be of good fire-bricks on the bed. The furnace is nine inches square; total height twenty-seven inches. From the top of the flanch to the bottom of the flue the interval is eighteen inches; the flue is four inches high; the height above is five inches; flue seven inches long, and keeps opening into the chimney, as may be seen at fig. 3 at E. If the chimney is under twenty-five feet in height, a larger flue is requisite; and if beyond thirty-five feet, a smaller flue will throw the heat more regularly through the furnace. In general, however, more harm ensues from too small than too large a flue. G is the floor-line, and also represents the edge of a grate which covers the ash-pit, which is better seen on the ground-plan, fig. 3, and in fig. 2 at H. This grate lies nine inches from the bars, having an open space for the admission of air. It projects twenty-four inches outwards, and serves the operator to stand upon.

I I, in figs. 1 and 2, is the ash-pit. In fig. 3, which is a ground-plan of the chimney and furnaces, C is the annealing or cementing furnace, in which the crucibles are annealed or baked to a bright red heat, and from thence introduced, along with the matter to be operated upon, into the assay-furnace. It also serves instead of a cementing furnace, being easily made to produce a heat of 100° of Wedgewood. It may be made of any size, from nine to fourteen inches square; a nine-inch chimney being sufficiently wide to the extent of an eighteen-inch furnace.

The chimney to each furnace is carried up five feet perpendicular; they then gradually incline to the centre opening, which they enter about twelve feet above the flues. L, L, L are dampers. From the grates of this assay-furnace to the top of the chimney the interval is thirty-three feet.

This furnace has melted 400 grains of malleable iron in ten minutes, and half a pound from lumps in forty minutes. If the materials to be operated upon are prepared with judgment, any experiment to the extent of half a pound of matter may be performed in half an hour, and less quantities in much less time. When approaching to its highest heat, a Stourbridge clay crucible (which drops in 168° of Wedgewood) will disappear in fifteen minutes from the time that it is put in. The first five bring it to 140° of Wedgewood, at which cast iron boils. Steel boils in it at 160°, and malleable iron boils in it at 170° to 172° of Wedgewood. It is probable, however, that the advantages of this furnace do not result from the height of the chimney (which is not so great), or from the size of its opening. More, it is likely, depends upon the flue, the opening of the grate bars, the size of the fuel, and particularly the feeding of the fire.

Muffle furnaces.

In many cases it is desirable to heat the articles of manufacture without exposing them to the smoke or dust arising from the fire or flame. This gives rise to a variety of furnaces variously adapted to the purpose; a kitchen oven is a furnace of this description; also the brass-founder's hot-plate or lacquering furnace; the furnaces used by enamellers; and all the different kinds known by the name of muffle-furnaces, in which a close vessel or cavity is formed above the fire-place, or in the draft of heated air from it, with a door opening externally, and by this the articles to be heated are introduced. Plate CCLII. fig. 4, represents a very convenient lacquering furnace or hot-plate for brass-founders. It stands at some distance from the wall of the apartment. The fire-place is immediately under the plate, and the flue carried horizontally into the chimney. Above the plate there is a square cover or box of tin plate, open below, which can be let down over the plate, and encloses the articles as in an oven.

Figs. 5 and 6 represent a convenient furnace for enamellers. It is merely a common air-furnace, similar to those already described, with a close vessel of earthenware placed over the fire-place, the latter being swelled out to allow the heated air to ascend on each side of the vessel. A is the fire-place; B the ash-pit; *a* the grate; C the vessel with its door; D the chimney; and *d* the damper; the other parts to be understood. This furnace may also be used for assaying metals by cupellation.

Figs. 7, 8, and 9, represent a muffle-furnace for producing very intense degrees of heat, and which was employed by Pott, and afterwards by D'Arcet, in their experiments on earths and stones exposed to a continued and violent heat. The fire-place or body of the furnace, B B, is in the form of an oblong coffer, swelling out in the middle. A shows the hole for the muffle; and the dome or upper part of the furnace is shown in D D, with a large door C, for introducing the fuel; *g* is the grate, *s* the ash-pit; and the other parts will be understood.

For an account of the glass-house furnaces, and those in the potteries and other manufactories, we must refer to the respective articles in this work.

In regard to furnaces for steam-boilers, the object of these, as already mentioned, is to produce rapidly a large quantity of heat for the generation of the steam. For this purpose the fire-place and grate are of great extent, and the flame and heated air, after striking the bottom of the boiler, is conveyed in flues along the bottom, and then round and round the sides, so as to deliver the whole of the heat, or as much of it as possible, to the water, before it ascends into the chimney. Figs. 8, 9, 10, Plate CCLIII. represent a furnace and boiler of this description. A is the fire-place; B, B, the grate bars; C, C, the boiler; D, D, D, the flues running under and around the boiler, and terminating in the chimney, E. For a more particular account, we must refer to the article Steam-Engine.

In all these furnaces, and particularly those for steam-engines, a very important object has often been attempted, namely, a consumption of the immense volumes of smoke occasioned by the large fires which must be kept up for their use. For an account of these, see Smoke and Steam-Engine.

Figs. 11, 12, 13, and 14, represent the forms of fire-tongs found useful in the operations connected with furnaces.

Furnaces are of very extensive use in the numerous processes of chemistry, and are variously constructed, according to the notion of the chemist, the uses required, or the means within his reach. They may be divided into three kinds; crucible-furnaces, wind-furnaces, and blast-furnaces. The first are used with charcoal, or, in the larger ones, with charcoal mixed with coke. The draft for the supply of air is obtained from the mere height of the crucible, or by the addition of a funnel pipe. In the wind-furnaces, the draft is obtained by connecting them with the chimney of the laboratory, and therefore more powerful, and better adapted for various uses. In the blast-furnace, again, the air is supplied by bellows; and furnaces of this kind are capable of producing the most intense degree of heat required. The crucible-furnaces are thus described by Professor Faraday, in his well-known work on Chemical Manipulation.

An exceedingly useful furnace, either in a large or small laboratory, may be made out of a black-lead or earthen crucible. The proper crucibles for this purpose are known by the name of *blue pots*, and may be had of almost every size less than the height of twenty-two inches, and of twelve or fourteen inches diameter in the top. They are made of clay and plumbago mixed, and are easily cut by a saw, rasp, or file. The price of one which will make a very good furnace for small operations is about six shillings.

One of these vessels, of the height of twelve inches, and seven inches in width at the top within (Plate CCLIII. fig 1), will make a very useful furnace for the igniting of a small crucible, heating a tube, or distilling with large glass retorts at moderate temperatures, or with smaller glass or earthen retorts at higher temperatures. It is first, in the course of preparation, necessary to have certain round holes pierced in it. These are easily made; a gimlet, bradawl, or other small instrument, is to be used to penetrate the sides; and the small apertures thus produced are to be enlarged with a rat's-tail and round rasp, and ultimately finished with a half-round rasp, which will make them of the size required. Four of these holes are to be placed at equal distances from each other, and about two inches from the bottom of the pot. They may be one and a fourth or one and a half inch in diameter. A second ring of holes, five or six in number, is to be made half way between the top and bottom of the pot, and a third row of five or six within two inches of the top. These holes should be rather smaller than the four lower ones.

The pot should now be bound round with iron or copper wire, to hold it together when it cracks, and a handle made to it of iron wire.

A small round grate of cast iron is only wanting to render this furnace complete for many operations; and several of these grates of different sizes should be ready at hand to drop in, and fit at different heights, as may be required. The part below the grate then forms the ash-pit, and the part above forms the body of the furnace. For the purpose of regulating the fire, if this requires to be diminished, the air-holes can be closed with stoppers made of soft brick or old blue pots; and, to increase the temperature, the body of the furnace itself may be enlarged by setting on the top of it a portion of an old pot, as in fig. 2, cut off so as to form a ring, several of which may be added as occasion requires; and they increase considerably the draft as well as the capacity of the furnace. Another simple method of increasing the power of these furnaces is to set on the top a piece of straight funnel pipe, as at fig. 3, two feet long, four inches diameter, opening out below like a funnel, till it is about eight inches diameter, with a wooden handle for the convenience of taking off or putting on. These simple furnaces are very powerful, and are capable, without difficulty, of raising a crucible two and a half inches in diameter to a white heat. In fact, all the ignitings and heatings which belong to the analysis of siliceous and other minerals have long been made in furnaces of this kind at the Royal Institution.

If the funnel-pipe in one of these crucible furnaces be connected with any chimney or flue in the laboratory, which is easily done by kneeing the pipe at the top, and having two or three short pieces to fit in for adjusting it to different lengths, as at fig. 4, its power is greatly increased, and in fact it becomes a wind furnace. The funnel termination at the bottom should be lined with fire-clay, and have an opening for the introduction of fuel, to be closed by a stopper when the fire is in order; or a still better arrangement is to continue the furnace upwards by a deep ring with the feeding apertures in it, as at fig. 5.

On the same principle with the crucible-furnace is a small portable furnace contrived by Mr Knight, and represented at Plate CCLIV. fig. 1, and consisting of a cylinder of sheet-iron lined with an earthy composition. A B is the fire-place; B C the ash-pit, closed on all sides excepting at the register door, D, where air is admitted; E is an opening for fuel; F a recess for the neck of a retort. Fig. 2 is a funnel top for the furnace, with a pipe above extending by other lengths into the chimney. Fig. 3 is a sand-bath, which can be used in place of the dome, with a pipe rising up from it.

Dr Black's portable furnace.

On the same principle is the well-known portable furnace of Dr Black, represented at fig. 4, Plate CCLIV. which is the most complete of the kind which has yet been contrived. It is made of sheet iron, formed into an elliptic shape for the purpose of getting a chimney separate from the body of the fire-place, and is carefully lined with clay well tempered. A B is the fire-place; B C the ash-pit; E a sliding door for the admission of fuel; D another door for the same purpose, and also for the introduction of a muffle. Fig. 5 is a cover, and fig. 6 a sand-bath. F is the chimney, which is lengthened by pipes, and connected with the chimney of the house.

On the same general principle of the wind-furnace is the general laboratory or table-furnace, which, being of considerable magnitude, is fixed in the laboratory, and forms one of the most important and useful pieces of apparatus which the chemist employs. From the extreme facility which, if conveniently arranged, it gives to every operation, its use is partly domestic, partly chemical;

for it has to warm and air the place, occasionally to heat water, as well as to supply the means of raising a crucible to ignition, or of affording a high temperature to flasks through the agency of a sand-bath.

These objects are best obtained by those furnaces which are built with a table top. The fire-place itself is constructed of brick-work with iron front and fittings; and the flue being carried horizontally for three or four feet, is afterwards carried off to and connected with the main flue existing in the wall. The fire-place and horizontal flue are covered with a large plate of cast iron, of from two to three feet in width. This is formed in the middle, over the heated part, into sand-baths; a round moveable one over the fire itself, and a long fixed one over the flue. The sand-baths supply every gradation of heat, from dull redness, if required, down to a temperature of 100° or lower; whilst on each side of them exists a level surface, which answers every purpose of an ordinary table, and supplies extraordinary facilities to experiments going on in the sand-bath or furnace. Nor are these advantages gained by any serious sacrifice of heating power in the furnace itself; for it is easy so to construct it as to make its ordinary combustion not more rapid than that of a common fire, and yet, by closing the fire-door and opening the ash-pit, to obtain a heat that will readily melt gold, silver, or cast iron.

A furnace like this is best placed in the middle, or towards one end of the laboratory, independent of the wall; for then it most effectually warms the air of the place, and there is working room all round it. The flue may then either descend and be carried off for a short distance under ground, or it may be connected by a funnel pipe with the upright draught chimney. But if more convenient, either as occupying less of the room of a small laboratory, or for other reasons, it may be placed with advantage against one side; and where the laboratory is made out of a room previously built, the best situation is generally against the fire-place, and the flue of the furnace is then easily connected with the chimney previously existing. When a furnace of this kind stands against the wall, it is frequently advantageous to construct a wooden hood over the sand-bath, to receive the fumes evolved during the digestions and solutions made upon it, and conduct them away to the chimney.

Being in constant requisition as a table, a furnace of this kind should be about thirty-four or thirty-five inches in height; its other dimensions, and even its form, must depend upon the space that can be allotted for it; and the following is a more particular description of the one in the laboratory of the Royal Institution, constructed under the direction of Mr Brande. It is represented at fig. 7, Plate CCLIV., and in section at fig. 8 through the line AB. It has the brick-work fifty-two inches in length and thirty-eight in width; the iron plate, including sand-bath, being fifty-seven inches by forty-two. Others have been constructed, the plates of which are only forty inches by twenty-seven. The principal part of this furnace is necessarily of brick-work, only the top plate, with the backs and the front, being of iron. The front is a curved iron plate, having two apertures closed by iron doors, one belonging to the fire-place, and the other to the ash-pit. It is thirty-four inches high and fourteen inches wide. The ash-hole door moves over the flooring beneath; the bottom of the fire-place door is twenty-two inches from the ground, and the door itself is eight and a half inches by seven. This front is guarded within, at the part which encloses the fire, by a strong cast-iron plate, having an opening through it, corresponding to the door of the fire-place. It has clamps attached to it, which, when the furnace is built up, are enclosed in the brick-work. In the setting or building of the furnace, two lateral brick walls are raised on each side the front plate, and a back wall at such a distance from it as to leave space for the ash-hole and fire-place. These walls are lined with Welsh lumps where they form the fire-chamber. Two iron bars are inserted in the course of the work, to support the loose grate bars in the usual manner, the grate being raised nineteen inches from the ground. The side walls are continued until of the height of the front, and are carried backward from the front until in two parallel lines, so as to afford support for the iron plate which is to cover the whole. The back wall of the fire-place is not raised so high as the side walls by six inches and a half, the interval which is left between it and the bottom of the sand-bath being the commencement of the flue or throat of the furnace. In this way the fire-place, which is fourteen inches from back to front, and nine inches wide, is formed, and also the two sides of the portion of the horizontal flue which belongs to the furnace, and is intended to heat the larger sand-bath. The bottom of this part of the flue may be made of brick-work, resting upon bearers laid on the two side walls; or it may be a plate of cast iron, resting upon a ledge of the brick-work on each side, and on the top of the wall which forms the back of the fire-place. When such an arrangement is adopted, the plate must not be built into the brick-work, but suffered to lie on the ledges, which are to be made flat and true for the purpose; for, if attached to the walls, it will by alternate expansion and contraction disturb and throw them down. The ends of the side walls, forming as it were the back of the furnace, may be finished either by being carried to the wall against which the furnace is built, or enclosed by a piece of connecting brick-work, to make the whole square and complete; or a warm air cupboard may be built in the cavity beneath the flue, and the door made to occupy the opening between the walls. Occasionally the flue may be required to descend there, and pass some distance under ground. These joints should be arranged and prepared before the plate constituting the top of the furnace is put on to the brick-work, so that when the plate with its sand-baths are in their places, they may complete the portion of the horizontal flue by forming its upper side.

The size of this plate is the first thing to be considered, and having been determined upon from a consideration of the situation to be occupied by the furnace, and the places of the sand-bath also having been arranged, the brick-work must then be carried up, so as to correspond with these determinations, and with the plate itself, which in the mean time is to be cast. The sand-bath and the plate are to be formed in separate pieces. The bath over the fire is best of a circular form, and of such diameter, that when lifted out of its place, it may leave an aperture in the plate equal in width to the upper part of the fire-place beneath; so that a still or cast-iron pot, or a set of rings, may be put into its place over the fire. The other sand-bath must be of such a form as to correspond with the shape and size of the flue beneath. These vessels are to be of cast iron, about three tenths of an inch thick; their depth is to be two and a half inches or three inches, and they are to be cast with flanches, so as to act in the corresponding depressions of the plate, that the level of the junctions may be uniform. This will be understood from the accompanying sections of the furnace, see fig. 8, given through the line A B of the view. It is essential that these sand-baths be of such dimensions as to fit very loosely into the apertures in the plate, a space of the eighth of an inch or more being left all round them when cold, as shown in the section, otherwise, when heated, they will expand so much as entirely to fill the apertures, and even break the plate. The plate itself should be half an inch thick.

When the plate and its sand-baths are prepared, and the brick-work is ready, the furnace is finished by laying the plate on the brick-work, with a bed of mortar intervening. If the walls are thin, or any peculiarity in their arrangement occasions weakness, they should be bound together, within by cranks built into the work, and without by iron bands. The alternate changes of temperature from high to low and low to high, to which the furnace is constantly subject, renders it liable to mechanical injury, in a degree much surpassing that which would occur to a similar piece of brick-work always retained nearly at one temperature.

The sand-baths which have been described are liable to an accident that has induced some chemists to substitute others made of wrought iron. When first heated, they frequently, indeed generally, crack from the unequal expansion in different parts; and the plate itself is subject to the same accident. If constructed of wrought iron, this effect is not produced; but then, after being used some time, they warp into very irregular and inconvenient forms, especially if made of thin metal; whilst, on the contrary, those of cast iron, when cracked, are rarely injured for the uses to which they are to be applied, and seldom suffer further change.

These baths should have washed sea-sand put into them. It is heavy, and occasions no dust when moved; whilst, on the contrary, unwashed and bad sand contains much dirt, and occasions great injury in experimenting. A piece of straightened iron hoop, about twelve inches in length, should lie on the furnace, as an accompaniment to the baths, being a sort of coarse spatula with which to move away the sand.

The circular sand-bath is frequently replaced by a set of concentric rings, or a cast-iron pot, see fig. 9. The rings are convenient for leaving an aperture over the fire of larger dimension, according as a larger or smaller number are used at once; and being levelled at the edges, fit accurately into each other, without any risk of becoming fixed by expansion. The external one, like the sand-baths, should be made smaller than the depression in the furnace plate in which it rests. The iron pots are of various sizes, and adapted to the furnace by means of the rings. A red heat is easily obtained in them for sublimation.

In cases where a greater heat is required than can be obtained by the table furnace, or any of the portable furnaces already described, other wind furnaces may be constructed by proportioning the size of the chimney to that of the furnace, much surpassing these in the intensity of heat produced; but in these and other cases it is better to have recourse at once to the *blast-furnace*, the operations being more manageable and expeditious, the heat greater, and the consumption of fuel smaller. By a little contrivance, one of the crucible furnaces before described is easily converted into a blast-furnace, and a very high temperature for small vessels obtained. This is done by closing the holes of the ash-pit with the stoppers, except one, and applying to that the nozzle of a pair of double-hand bellows, from which a draft is to be urged, and the furnace aided at the same time by the piece of upright funnel pipe; the fuel is to be charcoal.

A very powerful blast-furnace on a small scale has been contrived by Mr Aikin; it is represented at fig. 10, and is all made out of broken pots. The lower piece, A, is the bottom of one of these pots, cut off so low as only to leave a cavity of about an inch deep, and ground smooth above and below. The outside diameter over the top is five and a half inches. The middle piece or fire-place, B, is a larger portion of a similar pot, with a cavity about six inches deep, and measuring seven and a half inches over the top, outside diameter, and perforated with six blast-holes at the bottom. These two pots are all that are essentially necessary to the furnace for most operations; but when it is wished to heap up fuel above the top of a crucible contained, and especially to protect the eyes from the intolerable glare of the fire when in full height, an upper pot, C, is added, of the same dimensions as the middle one, and with a large opening in the side, cut to allow the exit of the smoke and flame. It has also an iron stem with a wooden handle (an old chisel answers the purpose very well), for removing it occasionally. The bellows, which are double, D, are firmly fixed by a little contrivance, which will take off and on, to a heavy stool, as represented in the plate; and their handle should be lengthened so as to make them work easier to the hand. To increase their force on particular occasions, a plate of lead may be firmly tied on the wood of the upper flap. The nozzle is received into a hole in the pot, A, which conducts the blast into its cavity. Hence the air passes into the fire-place, through six holes of the size of a large gimlet, drilled at equal distances through the bottom of the pot, and all converging in an inward direction, so that if prolonged, they would meet about the centre of the upper part of the fire. No luting is necessary in using this furnace, so that it may be set up and taken down immediately. Coke, or common cinders taken from the fire when the coal ceases to blaze, sifted from the dust, and broken into very small pieces, form the best fuel for higher heats. The fire may be kindled at first by a few lighted cinders and a small quantity of wood charcoal. The heat which this little furnace will afford is so intense, that its power was at first discovered accidentally by the fusion of a thick piece of cast iron. The utmost heat procured by it was 167° of Wedgewood's pyrometer, when a Hessian crucible was actually sinking down in a state of porcelaneous fusion. A steady heat of 155° or 160° may be depended on if the fire be properly managed and the bellows worked with vigour.

The following is a description of a most excellent blast-furnace, which has been in use for some years in the laboratory of the Royal Institution, and is represented at fig. 11. It is sufficiently powerful to melt pure iron in a crucible in twelve or fifteen minutes, the fire having been previously lighted. It will effect the fusion of rhodium; and even pieces of pure platinum have sunk together into one button in a crucible subjected to its heat. All kinds of crucibles, including the Cornish and the Hessian, soften, fuse, and become frothy in it; and it is the want of vessels which has hitherto put a limit to its applications. The exterior consists of a blue pot, eighteen inches in height and thirteen inches in external diameter at the top. A small blue pot of seven and a half inches internal diameter at the top had the lower part cut off so as to leave an aperture of five inches. This, when put into the larger pot, rested upon its lower external edge, the tops of the two being level. The interval between them, which gradually increased from the lower to the upper part, was filled with pulverized glass-blowers' pots, to which enough of water had been added to moisten the powder, which was pressed down by sticks, so as to make the whole a compact mass. A round grate was then dropped into the furnace, of such a size that it rested about an inch above the lower edge of the inner pot: the space beneath it, therefore, constituted the air chamber, and the part above the body of the furnace. The former was seven and a half inches from the grate to the bottom, and the latter seven and a half inches from the grate to the top. Finally, a horizontal hole, conical in form, and one and a half inch in diameter on the exterior, was cut through the outer pot, forming an opening into the air-chamber at the lower part, its use being to receive the nozzle of the bellows by which the blast was to be thrown in. The furnace being thus completed, the next object was to dry it gradually, that when used it might not be blown to pieces by confined aqueous vapour; a charcoal fire was therefore made in it, and left to burn some hours, being supplied with air only by the draught through the hole into the chamber beneath. When vapours ceased to be formed, the furnace was considered to be ready for use.

This furnace has always been used with a pair of large double bellows mounted in an iron frame, the furnace being raised upon a stool, so as to bring the aperture of the air-chamber to a level with the nozzle of the bellows. The latter has generally been inserted in the aperture; for this and similar furnaces are of such depth compared to their width, that when charged with a crucible and fuel, there is so much resistance to the passage of the air, when urged by a blast competent to create and sustain a vivid combustion, that a part returns by the side of the nozzle, if the aperture be left open. The bellows spoken of is far larger than necessary for the furnace described, and is rarely worked to one third of its power; for otherwise the heat rises so high as to destroy the crucible, and the results are lost. It is, however, at all times advisable to have an abundant command of air.

The heat produced in this furnace is such as at every violent operation to cause the production of some slag from the melting of the inner surface of the furnace itself, where the combustion has been most vivid. The slag running down the interior, collects round the edge of the grate, and should be removed with a chisel and hammer, or with an iron rod, after each operation, that the grate may be clear and free of obstruction for the next process. When in the course of time the interior of the furnace is so far injured as to become thin and weak, it must be displaced, and the furnace restored to its original state by the introduction of a new inside, as before.

The fuel to be used in this furnace is coke. Its consumption is very small, considering the heat that is obtained in consequence of the short period of each operation. The superiority of the blast-furnace over the wind-furnace, in many operations for which high temperatures are required, depends upon the rapidity of its action. It is requisite to employ this furnace in the open air, or under a well-arranged vent; for an immense number of sparks, much flame, and a current of hot air, are projected during its operation, which might occasion serious mischief in a room, unless the ceiling were at a considerable height, or guarded by a metal screen.

The *fuel* to be used in furnaces is of three kinds, coal, coke, and charcoal. *Coal* is the ordinary fuel for the laboratory table furnace, or that intended to be in use every day, and to serve for fusions, roastings, and other operations, for which its temperature may be sufficient. It is very desirable that this coal should be good, and not of the kind which contains much sulphur, or an abundance of earthy matter; for the first interferes with various fusions and ignitions, and the latter renders the fire dirty and dusty, and, when the temperature is raised to a high point, causes an abundance of clinkers. On certain occasions to be hereafter distinguished, especially if the coal be sulphureous and bad, it may be necessary at times to use both coke and charcoal in the table-furnace. Coal should never be used in the blast-furnace; for, in consequence of its softening and swelling by heat, it aggregates, closes the small channels by which the air finds a passage through the fuel, and impedes the combustion.

Coke is in constant requisition. It varies in quality with the coal from which it is obtained. Such as is intended for the service of the blast-furnace should be free from sulphureous, earthy, and metallic matter. Of this kind is the Staffordshire coke, which may be obtained at various wharfs on the canals near London. It is frequently so little altered in appearance as to resemble the original coal. It burns completely away in a blast-furnace, leaving scarcely a trace of slag, so that after several successive portions have been introduced, no material quantity of refuse is produced upon the grate, nor any thing that will act seriously on the crucible as a flux.

On the contrary, if common gas-coke be used in this furnace, the oxide of iron and earthy matter which it contains is so abundant, that slag is soon produced, which flowing over the crucible, corrodes and destroys it.

The *charcoal* intended for laboratory use may be of the ordinary kind, and must not be either too large or too small. If large, the pieces should be broken down, or they will be unfit for use in the crucible furnaces, for which it is principally intended. Charcoal is a quick fuel; but burning with facility, a small quantity of it can be easily retained in a state of regular combustion; and hence, in cases where but little space intervenes between the substance to be heated and the side of the furnace, or when a small temporary fire is required in the air, it is very convenient. Where Staffordshire coke will burn, and, by means of a blast or a draught of air, will give sufficient intensity of heat, it is very superior to charcoal in duration. Occasionally a mixture of coke and charcoal is convenient, since it affords a combination possessing the qualities of permanency and freedom of combustion.

A charcoal box is almost as essential in a laboratory as one for coal, and should have its appointed place.

It must be remembered, that all operations with furnaces should be carried on in safe situations; care being taken that no danger be incurred by the ascent of sparks, flame, or hot air, by lateral vicinity to combustible bodies, or by standing on an unprotected wooden surface.

When small furnaces are placed upon tables, stools, or trays, a brick or a piece of sheet iron should be interposed, according to the mode by which the heat is likely to be communicated.

For further information on the subject of furnaces, see the articles already referred to, and others connected with particular arts where they are used. (c.)

FURNEAUX ISLANDS, a cluster of islands in Bass Strait, between New Holland and Van Diemen's Land. The exact number of these islands has never been ascertained. The principal are, Great Island, which exceeds forty miles in length, Cape Barren Island, and Clarke's and Preservation Islands. There are, besides, several other smaller islands, and numerous islets. These islands are barren and unproductive, being sandy in the lower parts, containing swamps and pools, and being overrun with brushwood and stunted trees, which rarely exceed the height of twelve feet. A singular phenomenon appears in Preservation Island, where, in a certain spot, the trees have undergone a partial petrifaction towards the roots. Two species of seals are found here; as also the kangaroo, wombat, and duck-billed ant-eater. Innumerable flocks of sea-birds, amongst which is the sooty peterel, haunt the shores. These islands are resorted to for the seal fishery, and afford a temporary residence to those employed in it, the islands being uninhabited. The navigation is intricate; and there is a scarcity of fresh water. These islands were first visited by Mr Bass, along with Captain Flinders, in 1798.

FURNES, a city of the province of West Flanders, about two miles from the sea, on the canal from Dunkirk to Bruges. It is strongly fortified, and contains 3452 inhabitants. Long. 2. 34. 31. E. Lat. 51. 4. 23. N. It is the capital of a circle divided into four cantons, extending over 266 square miles, containing 76,547 inhabitants.

FURNITURE, a term in dialling, which denotes certain additional points and lines drawn on a dial, by way of ornament, such as the signs of the zodiac, length of days, parallels of declination, azimuths, points of the compass, meridians of chief cities, Babylonian, Jewish, or Italian hours, and the like.

FURRUCKABAD, a fortified town of Hindustan, in the province of Agra, and capital of the district of the same name. The town was built by a Patan colony about a hundred years ago, and is situated about a mile from the western bank of the Ganges. It contains a small citadel, and the palace of the nabob. The streets are wide, and the houses and open places are shaded with trees. It carries on an extensive trade with Cashmere and other parts of India, and derives considerable benefit from the extensive military cantonments of Futtehghur in its vicinity. A civil establishment for the administration of justice and the collection of the revenue was settled here, subordinate to the Bareilly court of circuit and appeal. Its inhabitants consist nearly in an equal proportion of Hindus and Mahommedans. It was under the walls of this place that, in the year 1804, Lord Lake defeated Holkar, who narrowly escaped being made prisoner. Long. 79. 33. E. Lat. 27. 33. N.

The district of Furruckabad is situated in a country enclosed between the Ganges and the Jumna, and between the twenty-seventh and twenty-eighth degrees of north latitude. It extends west along the banks of the Ganges, and formerly belonged to Canange; but in the early part of the last century it was assigned as a jagheer to an Afghan, whose descendants, after shaking off their dependence on the court of Delhi, became tributary to the nabob of Oude. In the year 1801 it was taken under the protection of the British, who assumed the civil and military administration of the country. Prior to this the country was in a wretched state; but tranquillity being now secured by the paramount power of the British, the country is in consequence improving.

FURTH, a city of the circle of the Rezat, in the kingdom of Bavaria. It stands at the junction of the rivers Rednitz and Pegnitz. It contains 1179 houses, and 12,705 inhabitants, of whom 2673 are Jews, which people have here an university with 200 students, two Hebrew printing presses, three Jewish schools, and an hospital. It is the most active manufacturing town in the kingdom; and though none of the establishments are upon a large scale, great quantities of goods are produced by them. The principal fabric consists of looking-glasses, innumerable small ones being made and distributed throughout Europe. Some hundreds of people are employed in making turnery ware; many in making locks, snuff-boxes, watches, leaf-gold, foil, spectacles, and the various other articles usually called Nuremburg goods.

FURTHCOMING, in *Scotch Law*, the name of an action competent to any person who has used arrestment in the hands of his debtor's creditor, for having the subject arrested declared his property.

FUSAROLE, in *Architecture*, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSE, or FUZE, in artillery. See FUSEE.

FUSEE, in clock-work, is that conical part drawn by the spring, and around which the chain or spring is wound.

FUSEE, *Fuze*, or *Fuse*, is a tube, generally made of very dry beech-wood, and sometimes of horn-beam, taken near the root, which, being filled with a composition of saltpetre, sulphur, and mealed powder, hard rammed, is driven into a loaded shell, which it serves to explode. The fuze must be of such length as to continue burning all the time the shell is in its flight or range, and to inflame the powder within as soon as it reaches the ground. Fuzes are of various kinds, according to the purposes to which they are applied. *Fusées à bombes à feu mort*, or bomb-fuzes with dead light, differ from the ordinary ones in this, that the eye, instead of being pierced and hollow, is full, and of a half spherical shape. *Fusées à grénades*, or fuzes for grenades, are made of the same quality of wood as that adopted for bombs, and required to be charged with the same care and precision. *Fusées d'obus*, or howitzer fuzes, are generally made of the same wood and composition as those of bombs, and are loaded in a similar manner. *Fusées volantes*, or rockets, are made of various dimensions, and serve as signals in time of war.

FUSIL, in *Heraldry*, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute than the other two in the middle. It is called in Latin *fusus*, a spindle, from its shape.

FUSELI, HENRY, a celebrated painter, was born at Zurich, in Switzerland, in the year 1741. He was the second son of Gaspard Fuessli, who had obtained some distinction as a portrait and landscape painter. Henry chose to alter the orthography of the family name, and also to place the date of his birth in the year 1745, instead of 1741. From his earliest years he was inspired with a love of painting, particularly of those works which have a sublime or imaginative character. Michel Angelo was his favourite artist; and he familiarized himself with his style, by making numerous copies of some prints of that great master's productions. Fuseli made rapid progress in learning, and united the love of literature, particularly of the poetry of Greece and Rome, with his devotion to painting. At the Humanity College of Zurich he became the intimate friend of the celebrated physiognomist Lavater. Here he studied the English language, and conceived such an ardent admiration of Shakspeare, that he translated Macbeth into German. He was induced, however, to leave his native place on account of a circumstance in nowise discreditable to his character. A magistrate in one of the bailiwicks of Zurich having committed some flagrant act of oppression, Lavater and he published a pamphlet exposing the affair, and so effectually did the friends succeed in their attempt, that the unjust ruler was compelled to leave the country. His friends, however, so annoyed Fuseli, that after taking his degree of master of arts, he quitted Zurich, first for Vienna and then for Berlin, whither he was accompanied by Lavater. In the capital of Prussia the two friends prosecuted their studies under the learned Sulzer; and here Fuseli extended his acquaintance with English literature. His genius and talents attracted the attention of Sir Robert Smith, British ambassador at the court of Berlin, and by the advice of that gentle-

Fuseli.

man he was induced to visit England, where he arrived in the year 1762. He had letters of introduction to several influential individuals, through whose instrumentality he obtained the situation of tutor to the son of a nobleman, whom he accompanied to Paris. His governorship, however, was short, and after returning to England he subsisted for some time by the labours of his pen. He wrote a number of pieces, but acknowledged none save the translation of Winkelman's work on painting and sculpture. About this period an angry controversy raged between Voltaire and Rousseau, and Fuseli printed a pamphlet in defence of the latter; but the whole impression caught fire, much to the satisfaction of the author, who afterwards felt ashamed of his production. Having shown some of his sketches to Sir Joshua Reynolds, the highly favourable opinion of that great painter determined the fate of our young artist, and he resolved on devoting himself entirely to the pencil. His first work was Joseph interpreting the Dreams of the Chief Baker and Butler; but nothing is known as to the manner in which it was executed or received, and the picture is now lost. In 1770 he visited Italy in company with Armstrong the poet. From his boyhood an enthusiastic admirer of Michel Angelo, he had an opportunity in Rome of studying that great artist in all his sublimity and grandeur, and for weeks together, as he loved to repeat, he would repose on his back gazing upon the magnificent ceiling of the Sistine chapel, and the lofty grandeur of the Florentine. Nor was the milder radiance which sheds such an inexpressible charm over the works of Raffaelle overlooked by our ardent student. But still, although he acknowledged the genius of that great master, he considered him as inferior to Michel Angelo, upon whom, fulfilling the injunctions of Reynolds, "he eat, he drank, he slept, he waked." From Rome he transmitted several pictures to England, two of which were taken from Shakspeare; namely, the Death of Beaufort, and a scene from Macbeth. After visiting his father at Zurich, he returned to London in 1779. In 1782 appeared his celebrated work entitled Nightmare, a subject peculiarly adapted to his genius, and which at once stamped him as a great and original genius. The idea of the Shakspeare gallery having been started at the table of Alderman Boydell, it was eagerly caught up by Fuseli and other painters present. It was soon afterwards realized, and, as might have been expected, our artist grappled with the wildest passages of the dramatist. For this institution he painted eight of his best pictures, of which the Ghost in Hamlet is considered as the noblest. Other pictures followed, the subjects of which were taken from Dante, Virgil, Sophocles, and other poets; and the fame of Fuseli having spread far and wide, he was in 1790 elected a royal academician. In the course of the next nine years he painted forty-seven pictures from Milton, which were afterwards exhibited as the Milton gallery. They all more or less evince the vigorous imagination of the painter. The Lazar House is most admired by men of vertù; but the rising of Satan at the touch of Ithuriel's spear is the favourite of the multitude. In 1799 he succeeded Barry in the professorship of painting, and, in 1804, Wilton as keeper of the Royal Academy. In the year following he published an improved edition of Pilkington's *Dictionary of Painters*, which, however, added but little to his reputation, although he introduced a great number of new names as candidates for pictorial celebrity. In 1807 the students of the Royal Academy presented him with a silver vase designed by Flaxman; and ten years afterwards he was presented with the diploma of the first class in the Roman Academy of St Luke. From this period until his death Fuseli exhibited twelve pictures at the academy, neither the fervour of his fancy nor his skill of hand having in the least failed. Whilst on a visit to the Countess of Guildford at Putney Hill, he became seriously unwell; and his indisposition increasing, he expired there, on the 16th of April 1825, in the eighty-fourth year of his age.

As a painter, the merits of Fuseli are of a high order in the line to which he applied himself. His mind was daring, and in dealing with themes of terror and imagination he evinced an originality and skill not surpassed amongst English artists, for to England he belongs by adoption. As a professor of painting, his chief aim was to impress his audience with a sense of the nobleness of art, and the high purposes to which alone it ought to be dedicated. His lectures and other literary compositions evince the same characteristic attributes of mind. In many of his criticisms upon painters and painting, particularly his celebrated disquisition upon invention, he displays great originality of mind, with a lofty and impassioned eloquence. His lectures were published in one volume 4to.

FUSILIERS, Fusileers, or *Fuzileers*, are men armed with fusils or light muskets. When pikes were in use amongst the French, each regiment had only four fusileers, exclusively of ten grenadiers who also carried muskets. At present, fusils or muskets are universally adopted in all European armies, though some regiments still retain the name of fusileers, which was anciently applied only to that one which was exclusively armed with fusils.

FUST, John, a goldsmith of Mayence, in the middle of the fifteenth century, and a man not more distinguished for his riches than for his knowledge of the arts, shares with Guttemberg and Schœffer the glory of having invented printing. Guttemberg is generally considered as the first inventor of this art; and, according to some, Fust had only the merit, by no means a slight one, of supplying him with money; whilst others are of opinion that the goldsmith contributed both his funds and his industry towards the completion of the invention. But, however this may be, a partnership was formed between them in 1450, and it appears that these associates practised successively three sorts of impressions; first, the *tabellary*, that is, in carved tablets or plates, like our engravings on wood; secondly, the *xylographic*, or in moveable characters of wood; and, lastly, the impression in characters cast in moulds or matrices, analogous to, if not identical with, the stereotype founding of the present day. There is reason to believe, however, that Fust, notwithstanding his acquirements, contributed but little of his own invention to the operations of the partnership contracted with Guttemberg; since the latter appears to have been the first who thought of applying to regular compositions the same mode which had been long practised at the foot of engravings for their explanation; and since Schœffer, in inventing the punch, completed the discovery, if indeed this ought not to be considered as the discovery itself. Fust, zealous in favour of all that regarded his art, was so much delighted with the invention of Schœffer, that he gave the latter his daughter in marriage. The *Biblia Sacra Latina*, without date, in folio, and consisting of 637 leaves, is probably the first production of printing, and seems to have been executed between 1450 and 1455, during the partnership of Fust and Guttemberg; but some think that the impression was struck from the characters invented by Schœffer. In 1455, difficulties arose between Fust and Guttemberg, who, in consequence, separated on the 6th of November. But, in reimbursements of the sums he had advanced, Fust remained proprietor of the establishment, which he now carried on with Schœffer; and to this new partnership we are indebted for the Psalter, *Psalmorum Codex*, of 1457, the most ancient work printed with a date (reprinted in 1459, from the same characters, which also served for the re-impressions of 1490, 1502, and 1516); the *Durandi Rationale Divinorum Officiorum*, 1459; the *Constitutiones Clementis Quinti*, 1460; the celebrated *Biblia Latina*, of 1462, the first Bible with a date; and the treatise *De Officiis* of Cicero. Fust and Schœffer exercised printing until 1466, when Fust went to Paris, and is thought to have died of the plague which then ravaged that city.

Fust, the goldsmith of Mayence, and the promoter of printing, has, however, been sometimes confounded with Faust the magician, whose name is associated with so many imaginary horrors. The latter, born about the commencement of the sixteenth century, was the son of a peasant of Weimar, or, as some say, of Kundling. He was educated by one of his uncles, who caused him to study theology, and, notwithstanding a strong propensity to debauchery, he completed his course, and obtained the degree of doctor. But having become disgusted with this pursuit, he cultivated medicine and astrology, and in particular applied himself to the study of magic. From this time his historians are only insipid romancers, who relate a thousand absurdities respecting him. They make him conjure up the devil himself; employ an infernal spirit named Mephistopheles, with whom he made a paction for twenty-four years; descend into hell, and travel through the celestial spheres, as well as through all the countries of this sublunary world, everywhere surrounding himself with illusions, playing mischievous pranks, having commerce with Helen the wife of Menelaus, causing Alexander the Great to appear to Charles V., and, lastly, to terminate the whole in a suitable manner, having his neck twisted by the devil at the expiration of his compact with that personage. Much more infallible than even the illustrious Mathew Laensberg, Faust yearly circulated in Germany almanacks, which, being dictated by Beelzebub, could scarcely fail to have great success. Such are the marvellous feats related by George Rodolph Widman, who published at Franckfort, in 1587, 8vo, the history of John Faust, and Christopher Wagner his valet. This history, or rather this romance, reprinted at Berlin in 1590, and at Franckfort in 1591, re-appeared at Hamburg, 1598–1600, in three volumes 4to, with historical, physical, and moral commentaries, filled with ignorance and folly; and it was also translated into English, Dutch, and French. Adelung has honoured Faust with an article at the end of his History of Human Follies, where will also be found the *Conjurationes Fausti*, but without the mysterious figures which ought to have accompanied them, and by means of which the reader might easily perform the same prodigies as the magician of Weimar. The Germans, who are fond of the marvellous, have often brought upon the scene the descent of Dr Faust to the infernal regions. Of this number are the celebrated Goethe, Klinger, and J. F. Schink; whilst Trithemus, the most ancient of all, J. Manlius, Schaller, Wier, Del Rio, and even Camerarius and Gesner, have discoursed of Faust and his enchantments, of which Peter-Frederick Arpe has favoured the world with a catalogue. But notwithstanding the testimony of these writers, many others, perhaps with reason, regard this personage as entirely imaginary, and consider his history as a romance intended merely for amusement. Some, indeed, including Conrad Durius, are disposed to think that the legend of Faust is a satire fabricated by the monks against John Fust, one of the inventors of printing, who had incurred the resentment of these cenobites by being concerned in a discovery which superseded their useful functions as copyists of manuscripts; but others have shown that this opinion is not well founded. Upon the subject of Faust, the curious reader may consult Zeltner's *Schediasma de Fausto præstigiatore ex Joanne Fausto a quibusdam ficto;* Struvius in his *Introductio in not. Rei Litterar.* and in his *Bibl. Antiq.;* and Neumann's *Dissertatio Historica de Fausto præstigiatore*, Wittemberg, 1683, 1693, 1711, in 4to. (A.)

Fust, in *Architecture*, the shaft of a column, or the part comprehended between the base and the capital, and also called the naked.

FUSTIAN, in *Commerce*, a kind of cotton stuff, tweelled or ribbed on one side. Fustians should be altogether made of cotton yarn, both woof and warp; but a great many are made, the warp of which is flax, or even hemp. Fustians are made of several kinds, wide, narrow, fine, coarse; with shag or nap, and without it.

Fustian is also employed to denote an inflated or bombastical style of composition.

FUSTIGATIO, in the Roman customs, a punishment inflicted by beating with a cudgel. This punishment was peculiar to freemen; for the slaves were scourged with thongs.

FUTTEHGHUR, a town of Hindustan, situated on the western bank of the Ganges, three miles from the city of Furruckabad, formerly a very extensive military cantonment, but now occupied by the civil establishment of the Furruckabad district.

FUTTEHPOOR, a town of Hindustan, in the province of Agra, twenty-four miles from the town of that name. It was enlarged and embellished by Akbar, in honour of a celebrated saint, to whose prayers the Emperor Akbar thought that he was indebted for a son. The tomb of this saint is situated on a mountain near the town, and is still the resort of Mahommedan pilgrims. The place is enclosed with a high stone wall of great extent; but the space within appears never to have been filled with buildings. It presents at present a wide extent of ruined houses and mosques, interspersed with fields cultivated with rice and mustard, and a few tamarind trees; and nearly in the middle, on a high ridge of rocky hills, is a range of numerous palaces, serais, and other public buildings, in the best style of Mussulman architecture, with a noble mosque in good repair. Long. 77. 34. E. Lat. 27. 5. N.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers which form her breadth and capacity.

FUTWA, a town of Hindustan, in the province of Bahar, situated at the confluence of the river Pompon with the Ganges, nine miles south of Patna, over which is a good bridge, built of brick. In the year 1574, when the Afghan army was retreating before Akbar, the bridge broke down, and they were mostly either drowned or put to the sword. It is noted for the manufacture of table-cloths and sheeting. Long. 85. 28. E. Lat. 25. 30. N.

FUTTYPOOR, a town of Hindustan, in the province of Ajmeer, within the territory of the Teynagur rajpoots, and seventy miles north-north-west from Teynagur. Long. 75. 7. E. Lat. 27. 51. N.

FUTURE, something to be, or to come hereafter.

Future, or *Future Tense*, in *Grammar*, denotes an inflection of verbs, denoting that a thing will be in some time yet to come. See Grammar.

FYZABAD, a town of Hindustan, in the province of Oude, situated on the southern bank of the river Dewah or Gogra. This city is said to have owed its origin to the nabob Sufder Jung, who, in 1740, erected some temporary houses in an extensive garden at this place. His son Shuja Addowleh, after the battle of Buxar, removed his residence to this place, and gave orders for erecting a palace and other public buildings. The city was in consequence quickly enlarged, and rose into importance; but the nabob Assup Addowleh having transferred his residence to Lucknow, many of the houses, having been hastily built, fell into decay. It is still, however, a considerable city, and contains a numerous population, chiefly of the lower classes, the merchants and bankers having removed to Lucknow along with the court. It was the residence of the two celebrated Begums, the mother and grandmother of the last-mentioned nabob. Adjoining is the ancient city of Oude or Ayodha, the capital of the great Ram, who conquered Ceylon. The city contains some handsome tombs belonging to the reigning family; and its gardens are celebrated for grapes and other fruits. It is eighty miles east from Lucknow. Long. 82. 10. E. Lat. 26. 46. N.

G.

G, THE seventh letter and fifth consonant of our alphabet, though in the alphabets of all the oriental languages, the Hebrew, Phœnician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, G is the third letter. The Hebrews call it *ghimel* or *gimel*, a camel, by reason of its supposed resemblance to the hump on the back of that animal; and it bears the same appellation in the Samaritan, Phœnician, and Chaldee; in the Syriac it is called *gamel*, in Arabic *giim*, and in Greek *gamma*. The gamma, Γ, of the Greeks is manifestly the ghimel, ג, of the Hebrews or Samaritans; the difference between the gamma and ghimel consisting in this, that the one is turned to the right and the other to the left, according to the different manners of writing and reading which obtained amongst these different nations. From the Greeks the Latins borrowed their form of this letter; the Latin G being certainly a corruption of the Greek gamma, Γ, as might be easily shown, if our printers had all the characters and forms of this letter to be met with in the Greek and Latin manuscripts, through which the latter passed from Γ to G. Diomedes (lib. ii. cap. *De Litera*) calls G a new letter. His reason is, that the Romans had not introduced it before the first Punic war, as appears from the *Columna Rostrata* erected by Duilius, in which C is everywhere found instead of G. It was Sp. Carvilius who, as we learn from Terentius Scaurus, first distinguished between these two letters, and invented the figure of the G.

The G, however, is found instead of C on several medals (Vaillant, *Num. Imperat.* tom. i. p. 39); and Beger produces a medal of the *Familia Ogulnia*, where we find *Gar* instead of *Car*, which is the reading on those of Pâlin. But the C is more frequently seen on medals instead of G, as *Aucustalis*, *Callæcia*, *Cartacinensis*, &c.; not that the pronunciation of these words was altered, but only that the G was unskilfully or negligently cut by the workmen; as may be seen in different inscriptions of the eastern empire, where AVC is frequently found for AUG, and so in other cases. The northern nations frequently changed the G into V or W, as in *Gallus*, *Wallus*; *Gallia*, *Wallia*, *Vallia*, &c. But it must not be supposed that the French have changed the W into G; because they wrote *Gallus* long before *Wallus* or *Wallia* was known, as appears from all the ancient Greek and Roman writers. And yet it is equally true that the French change the W of the northern nations, and V consonant, into G; as *Willielmus*, William, into *Guillaume*; *Wulphilas* into *Gulphilas*; *Vascon* into *Gascon*, and so in other cases.

The letter G is a mute, and cannot be any way sounded without the help of a vowel. It is formed by the reflection of the air against the palate by the tongue, as the air passes out of the throat, or, as Martianus Capella expresses it, G *spiritus cum palato*; so that G is a palatal letter. The modern G takes its form from that of the Latins. In English it has two sounds; one from the Greek Γ, which is called that of the hard G, because it is formed by a pressure somewhat hard of part of the tongue against the upper gum, a sound which it retains before *a*, *o*, *u*, *l*, *r*; and the other, called that of the soft G, resembles that of *j*, and is commonly, though not always, found before *e* and *i*, as in *gesture*, *giant*, whilst at the end of a word it is always hard. To this rule, however, there are many exceptions. G is often hard before *i*, as *give*, &c. and sometimes before *e*, as *get*, &c. It is also hard in derivatives from words ending in *g*, as *singing*, *stronger*, &c. and generally before *er* at the ends of words, as *finger*. G is mute before *n*, as *gnash*, *sign*. G*h* has the sound of the hard G in the beginning of a word, as *ghostly*; in the middle, and sometimes at the end, it is quite silent, as *right*, *though*. At the end of a word *Gh* has often the sound of *f*, as *laugh*, *rough*, *tough*.

As a numeral, G was anciently used to denote 400; and with a dash over it thus, $\overline{\mathrm{G}}$, 40,000. As an abbreviature, G. stands for *Gaius*, *Gellius*, *gens*, *genius*, &c. G. G. for *gemina*, *gessit*, *gesserunt*, &c. G. C. for *genio civitatis* or *Cæsaris*. G. L. for *Gaius libertus*, or *genius loci*. G. V. S. for *genio urbis sacrum*; G. B. for *genio bono*; and G. T. for *genio tutelari*. In music, G is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name of *gamut*.

GABALE, in *Mythology*, a deity worshipped at Heliopolis under the figure of a lion with a radiant head.

GABARA, or GABBARA, in *Antiquity*, the dead bodies which the Egyptians embalmed and kept in their houses, especially those of such of their friends as had died with the reputation of great piety and holiness, or as martyrs.

GABARDINE, from the Italian *gavardina*, has been sometimes used to denote a coarse frock, or mean dress. In this sense it is used by Shakspeare in his Tempest and Merchant of Venice, and by Butler in his Hudibras.

GABEL (*Gabella*, *Gablum*, *Gablagium*), in French *Gabelle*, that is, *Vectigal*, has the same signification among the ancient English writers which *gabelle* has in France. It is a tax, but the term has been variously used for a rent, custom, service, and the like. Where it was a payment of rent, those who paid it were termed *gablatores*. When the word was used without any addition to it, it signified the tax on salt, though afterwards it was applied to all other taxes. See the article FRANCE.

GABEL, or *Gablona*, a city of the Austrian kingdom of Bohemia, in the circle of Buntzlau. It is surrounded with walls, and contains 380 houses, and 1980 inhabitants, who are chiefly employed in making woollen cloths. It is celebrated for a battle fought there in 1757, with the Prussians.

GABINIAN LAWS, in Roman antiquities, laws instituted upon several occasions by persons of the name of *Gabinius*.

GABINIUS, AULUS, a Roman general, the chief events of whose life are included between his tribunate, B. C. 67, and his death, B. C. 49. He seems to have been of an active, enterprising disposition, but without principle, and ready to prostitute his talents to advance his interests.

In the Mithridatic war, B. C. 81, he served under Sylla with considerable distinction; but it was not till he had reached the dignity of tribune that he took an important share in public transactions. He proposed to the people a law, by which an unlimited power over the Mediterranean was intrusted to Pompey, on the pretence of putting down the Cilician pirates; and though the senate could not prevent its enactment, they determined that Gabinius should not succeed in his desire of being appointed lieutenant to Pompey. Through the interest of Cæsar we find him consul, B. C. 58, and lending his official influence to Clodius to procure the banishment of Cicero. Neither the known wishes of the senate, nor the entreaties of the knights, could alter his determination, and Cicero found himself obliged to yield to the storm. The reward he received for this conduct was the province of Syria, and money from Clodius to enable him to equip his troops. Upon his arrival in Syria he made war on the Jews, and, having defeated Aristobulus, their king, compelled him to sue for peace. Gabinius addressed a public letter to the senate announcing his victory, and demanding that a day of public thanksgiving should be appointed. This the senate refused, and ordered him to return; but he was not of a disposition likely to attend to their orders, if it did not suit his inclination. He continued in Syria, and was preparing an expedition against the Arabians, when he received a letter from Pompey, requesting him to restore the exiled Ptolemy to his kingdom of Egypt. Though both the Sibylline books and the senate forbade an army to be led into Egypt, Gabinius disregarded all consequences, and immediately restored Ptolemy. Such conduct was heard with astonishment at Rome, and imperative orders were given him to return home. This time he thought proper to obey, and the exertions of Pompey and his friends procured his acquittal. In the civil wars he joined the party of Cæsar, and we find him commanding the troops in Illyria, where he was cut off by a body of the enemy, or, according to others, being shut up in Salona, died of vexation. (Appian. *Mithr.* 66, 94; *Bell. Civ.* 11, 14; *Syr.* 51; *Illyr.* 12, 25; Dion. Cass. xxxix. 55–63; *Hist. Alex.* 43.)

GABION, in *Fortification*, is a kind of basket made of ozier twigs, of a cylindrical form, having different dimensions, according to the purpose for which it is used. Some gabions are five or six feet in height and three feet in diameter, and serve in sieges to carry on the approaches, when these have advanced near the body of the place. Those used in field-works are from three to four feet in height, and from two and a half to three feet in diameter. Gabions of a still smaller size are placed along the top of the parapet, to cover the troops in firing over it.

GABLE, or GABEL *End*, of a house (from *gaval*, Welsh), is the upright triangular end from the cornice or eaves to the top of the house.

GABRES, or GAVRES, called also *Gebres*, *Guebres*, *Gevres*, and *Giaours*, a religious sect in Persia and India. The Turks call the Christians Giaours, or people of a false religion, or rather, as Leunclavius observes, Heathens or Gentiles; the word amongst the Turks having the same signification as Pagan or Infidel amongst the Christians, and denoting any thing not Mahommedan. In Persia the word has a more peculiar signification, being applied to a sect dispersed throughout the country, and said to be the remains of the ancient Persians, or followers of Zoroaster.

GABRIEL, the name of one of the principal angels in heaven. The name signifies The Strength of God.

GABRIELITES, in *Ecclesiastical History*, a sect of Anabaptists who appeared in Pomerania in 1530. They derive their name from Gabriel Scherling, who, after having been for some time tolerated in that country, was at length obliged to remove, and died in Poland.

GAD, a Jewish prophet, the seer or domestic prophet of King David, and his adviser in all matters of importance.

GAD, in *Ancient Geography*, a district of the Transjordan Palestine, situated between Gilead and the kingdom of Bashan on the north, and the kingdom of the Amorites on the south, having the Jordan on the west, and bounded by various tribes on the east. It is so called from a tribe of that name.

GADES, called by the Greeks *Gadeira*, an ancient city of Spain, situated on an island of the same name, now *Isla de Leon*, 750 stadia west of Calpe, the Straits of Gibraltar. It was placed on the western side of the island, being, it is said, founded by a colony from Tyre, 348 years before the building of Rome. It seems to have been a flourishing city at a very early period, being the central point from which the Phœnicians directed all their commercial expeditions to the west of Africa and Europe. From this city Hanno started in his exploratory expedition towards the western coasts of Africa, and the Carthaginian Himilco in his voyage to the north-western parts of Europe. Gades and Carthage alone reaped the fruits of their discoveries; they concealed the knowledge thus acquired from the rest of the world. Gades thus became one of the richest cities in Europe; and, as a proof, Strabo states that she could produce in his time five hundred knights, a greater number than could be found in any city of Italy excepting Rome and Padua.

In the first Punic war Gades submitted to the Carthaginians, and at the conclusion of the second it followed the example of the rest of Iberia, in yielding to the superior arms of Rome. From Julius Cæsar it received the privileges of a Roman colony, and at a later period the honorary title of Angusta Julia Gaditana. It was celebrated for a temple of Hercules, the ruins of which are said to be still seen at the tower of Saint Peter, on the side of the island nearest to the main land.

Gades gradually sunk, till in the fourth century we find Avienus lamenting bitterly over its fallen state, and adding that it afforded nothing worthy of notice, excepting the festival which was celebrated in honour of Saturn. In later times the city of Cadiz occupied the position of the ancient Gades.

GAETA, a fortified maritime city of the province Terra di Lavoro, in the kingdom of Naples. It is a very irregular and ill-built place, with a cathedral, several other churches and monasteries, and 14,125 inhabitants, who subsist chiefly on the coasting trade and the fisheries. The country around supplies good wine, oil, and fruit. On a hill opposite stands the walled castle of Otranto. Long. 13. 27. E. Lat. 41. 50. N.

GAFFAREL, JAMES, a French divine, and learned writer, born about 1601. He acquired great skill in the oriental and several other languages, and was particularly conversant in the cabalistic and occult sciences, which he learned, exposed, and refuted. Cardinal Richelieu made choice of him as his librarian, and sent him into Italy to collect the best manuscripts and books. He published a work entitled *Curiositez Innouies*. It is said the cardinal designed to employ him in his grand project for the reunion of religions. He died in 1681, aged fourscore.

GAGA, a small uninhabited island in the Eastern Seas, between the two islands of Waygiou and Gilolo. It has a harbour on the south side of the island, and produces sago and timber in abundance. Long. 126. 40. E. Lat. 0. 18. S.

GAGE, in our ancient customs, signifies a pledge or pawn, given by way of security. If the gage perish, the person who received it is not answerable for it, except in the case of extreme negligence.

GAGE was also used to signify a challenge to combat. In this sense it was a pledge, which the accuser or challenger cast on the ground, and the other took up as accepting the challenge. The gage was usually a glove, gauntlet, chaperoon, or the like.

GAGE, in nautical language. When one ship is to windward of another, she is said to have the weather-gage of such ship. The number of feet that a vessel sinks in the water is likewise called the ship's *gage;* and this is found by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under the water is the ship's gage.

GAGE, amongst letter-founders, is a piece of box, or other hard wood, variously notched, the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters.

GAGE, in joinery, is an instrument made to strike a line truly parallel to the straight side of any board or piece of stuff.

Sliding-GAGE, a tool used by the mathematical-instrument makers for measuring and setting off distances.

Sea-GAGE, an instrument invented by Dr Hales and Dr Desaguliers for finding the depth of the sea.

Bucket Sea-GAGE, an instrument contrived by Dr Hales to find the different degrees of coolness and saltness of the sea at different depths.

Aqueo-mercurial GAGE is the name of an apparatus contrived by Dr Hales, and applied in various forms to the branches of trees, for the purpose of determining the force with which they imbibe moisture.

Tide-GAGE is the name of an instrument used for determining the height of the tides.

Wind-GAGE is an instrument for measuring the force of the wind upon any given surface. See METEOROLOGY.

GAHRAH, a small town of Hindustan, in the province of Sinde, situated on the banks of a salt-water creek communicating with the sea, and navigable for small boats. The surrounding country is barren and sandy; and the dry and parching wind blows up the sand in clouds, so as nearly to blind both man and beast. Long. 67. 56. E. Lat. 24. 46. N.

GAILDORF, a bailiwick of the circle of the Jaxt, in the kingdom of Wurtemberg, extending over 148 square miles, and comprehending one city, two market-towns, and 253 villages, with 21,498 inhabitants. It is a mountainous district, better adapted to the breeding of cattle than the growth of corn. The capital, of the same name, situated on the river Kocher, contains 1341 inhabitants.

GAILLAC, an arrondissement of the department of the Tarn, in France, extending over 511 square miles. It is divided into eight cantons and eighty-four communes, and contains 63,376 inhabitants. The chief place is a city of the same name, situated on the Tarn, which is navigable as far as this town. The ware made near this city is the best of the department, and chiefly exported from Bordeaux to foreign markets. Gaillac contains 1503 houses and 6636 inhabitants. Long. 1. 45. E. Lat. 43. 30. N.

GAIN, the profit or lucre a person reaps from his trade, employment, or industry.

GAIN, in *Architecture,* is the workmen's term for the bevelling shoulder of a joist or other timber.

To GAIN the Wind, in nautical language, is to arrive on the weather side or to windward of some other vessel in sight, when both are plying to windward, or sailing as near the wind as possible.

GAINAGE, GAINAGIUM, in our ancient writers, signifies the draught oxen, horses, wain, plough, and furniture, for carrying on the work of tillage by the baser sort of sokemen and villeins.

GAINAGE is also used to signify the land itself, or the profit raised by cultivating it.

GAINSBOROUGH, a market-town of the county of Lincoln, in the hundred of Corringham, and the Lindsay division, 148 miles from London. It is advantageously situated on the right bank of the river Trent, by which it is divided from Nottinghamshire. The tide comes in with more rapidity, and rises higher, than in any other of the ports of England except Chepstow, though it is nearly forty miles from the Humber. The Trent being thus far navigable, conveys the agricultural produce of the vicinity to distant markets, and makes Gainsborough a kind of emporium for such heavy articles as coal, salt, timber, iron, and others; but it has no manufactures, and little other trade. There is no corporate body of magistrates. The market is held on Tuesday. The population amounted in 1801 to 4506, in 1811 to 5172, in 1821 to 5893, and in 1831 to 6658.

GALACTOPHAGI, and GALACTOPOTÆ, in *Antiquity;* persons who lived wholly on milk, without corn or the use of any other food. The words are compounded of *γαλα, γαλακτος, milk; φαγειν, to eat;* and ποτης, from πινω, *I drink.*

GALASHIELS, a town of Scotland, situated in a parish of the same name, which lies partly in the county of Roxburgh, and partly in that of Selkirk. The town stands upon a low piece of ground on the right bank of the Gala, about a mile above its embouchure into the Tweed. The old village of the same name is now abandoned and destroyed, and the new town has been built within the last fifty years. It consists of one long street, with some small lanes striking off from it, and also scattered clusters of houses, the whole being built of blue whinstone, and slated. Galashiels being situated in the midst of an extensive pastoral country, which yields abundance of wool, the manufacture of woollen cloth, and the spinning of woollen yarn, is carried on to a considerable extent, notwithstanding the disadvantage arising from expensive inland carriage, and the distance of the place from coal mines. The value of the manufactures of this description amount to about L.20,000 per annum, and the trade is upon the increase. The cloth produced here, which is coarse and strong, has long been remarkable for its durability; the quality, however, has been much improved within these few years. Only a small quantity of the goods manufactured is exported, the greater part of them being consumed at home. Flannels and blankets of an excellent quality are also made here from foreign wool. The tanning of leather and the dressing of skins are likewise carried on to some extent, and the town possesses a brewery. There are here several schools besides that for grammar, a parish church, and two or three dissenting meeting-houses. Galashiels is a burgh of barony. It is situated thirty-one miles from Edinburgh, five from Selkirk, and about five from Melrose. The population of the town and parish amounted in 1821 to 1545, and in 1831 to 1534.

GALATÆA, or GALATHÆA, in fabulous history, a sea nymph, daughter of Nereus and Doris. She was passionately beloved by the Cyclops Polyphemus, whom she treated with coldness and disdain; whilst Acis, a shepherd of Sicily, enjoyed her unbounded affection. But the happiness of these two lovers was disturbed by the jealousy of the Cyclops, who crushed his rival to pieces with a piece of a broken rock whilst he reposed on the bosom of Galatæa. The nymph was inconsolable for the loss of Acis; and as she could not restore him to life, she changed him into a fountain.

GALATIA, or GALLOGRÆCIA, a considerable province in the central part of Asia Minor, the boundaries of which it is impossible to determine with any degree of exactness. It lay towards the sources of the river Sangarius, being bounded on the north by Bithynia and Paphlagonia, on the east by Cappadocia, and on the south by Phrygia.

The Galatæ were a portion of that great Celtic race which is found from the earliest times in the valleys of the Danube and of the lofty Alps, and which began to press towards the east during the weakness of the Macedonian empire under the successors of Alexander. A large body of this people under their leader Brennus (B. C. 278), made their appearance in Dardania, a district of Macedon, with the intention of plundering Greece. Here a dispute arose, and a party of twenty thousand men under Leonorius and Lutarius, separating from the main body, directed their course through Thrace to Byzantium, now Constantinople, and encamping before it, laid this city and all the adjoining country under contribution. Perceiving the beautiful shores of Asia, and being invited by Nicomedes king of Bithynia, who was then at war with his brother Zipætes, to cross the straits, they willingly acceded to the request. They had no difficulty in deciding the contest in favour of Nicomedes, but, like the Saxons, they refused to evacuate the country when their services were no longer required; and so powerful did they find themselves amongst the effeminate inhabitants of Asia, that they even proceeded to parcel out to the three tribes of which they were composed, the Trocmi, Tolistoboii, and Tectosages, the several parts of Asia Minor. They, however, fixed themselves towards the sources of the Sangarius, and at last became so formidable, that even the kings of Syria consented to comply with their demands. It was Attalus king of Pergamus (about 235 B. C.), who first ventured to resist their extortions, and meeting them in the field, gained a complete victory. Not long afterwards Prusias king of Bithynia was also successful in an attack which he made on them. They continued, however, to be the terror of Asia, until the Romans, having defeated Antiochus the Great, king of Syria (B. C. 189), directed their arms against these marauders. A great portion of them were cut to pieces, and the remainder were happy to be allowed to retain quiet possession of their lands.

Strabo tells us that the whole of Galatia was originally divided into four principalities, at the head of each of which was a tetrarch; but in later times they were reduced to one. It seems that this change was made by the Romans in favour of Deiotarus, who had assisted them in the Mithridatic war. Some time afterwards the whole of Galatia came into the possession of the Romans, who made it a province of their empire. St Jerome states, that in his time they spoke the same language as the Treviri in Gaul. St Paul addressed one of his epistles to the Christians of Galatia. The possessions of the Tolistoboii were to the south, and their chief town was Pessinus; the Tectosages occupied the central parts of the province, having Ancyra for their capital; and the Trocmi were found in the north-eastern portion of the country, towards Pontus and Cappadocia, the chief town of which was Tavium. Their history is chiefly found in Livy, xxxviii. 12–27, 40; Polyb. *Fragm.* xxii. 16–24; Appian. *Mithr.* 114; Strab. xii. 566; Plin. v. 32.

GALATZ, a city of Moldavia, in the circle of Kohurlui. It is built on the banks of the Danube, is surrounded with walls, and is by far the best-constructed city in the whole principality. It contains seven Greek churches, 1200 houses, and 7000 resident inhabitants, besides numerous strangers always resorting to it as the chief place of trade for both Wallachia and Moldavia. These consist of Greeks, Arminians, and Jews, who bring German and Austrian manufactured goods, and some from more distant countries. The harbour in the river is very good, and admits ships of 300 tons to lie close to the quays. There are many vessels built as well for sea as for river navigation. Long. 28. 17. E. Lat. 45. 24. N.

GALAXY, in *Astronomy*, the long white luminous track which seems to encompass the heavens like a coronal or girdle, and which is easily perceivable in a clear night, especially when the moon does not appear. The Greeks call it γαλαξιας, *galaxy*, on account of its colour and appearance. The Latins, for the same reason, call it *via lactea*, or *milky way*. It passes between Sagittarius and Gemini, and divides the sphere into two parts. It is unequally broad, and in some parts is single, in others double. See ASTRONOMY.

GALBA, SERGIUS SULPICIUS, a Roman emperor, who was born B. C. 3 and died A. D. 69. He was descended from a family which had first risen to notice towards the latter years of the republic. His father, who was of consular rank, had some pretensions to be considered as an orator; he married Mummia, the grand-niece of L. Mummius, the conqueror of Corinth, and by her he had the emperor Galba. Of his youthful years we can give no account, excepting that he must have evinced early proofs of great abilities. Augustus is said to have foretold that he would be one of his successors on the imperial throne. We find him raised to the highest dignities of the state before he had reached the age fixed by law, consul A. D. 33, and then appointed by Caligula to the command of the troops in Gaul. On the death of that emperor (A. D. 40), he was strongly urged by his friends to put in his claim for the vacant throne; but he seems to have preferred the pleasures of retirement to the anxieties of a court. Claudius was so charmed with the moderation of his conduct, that he admitted him to his intimate friendship, and made him proconsul of Africa as a mark of his particular favour. Here he remained for two years, carrying the strictness of military discipline into all the civil arrangements of the province. On his return to Rome he retired to the privacy of the country, and took no part in public affairs till the middle of the reign of Nero. He was then invited by that emperor to assume the command of Hispania Tarraconensis, and it may be readily imagined that he did not venture to refuse such a request. This province he continued to govern for eight years; at first he distinguished himself by the severity with which he punished even venial faults, though the example given by Suetonius is a curious proof of the state of moral feeling in that age. The author expresses his surprise at the punishment of crucifixion, which Galba inflicted on a guardian who had poisoned his ward. Latterly, however, he changed his policy, and apparently passed his life in indolent repose, that he might give no cause of complaint to the suspicious Nero. That despot, however, thought him too powerful a pasha to be allowed to live, and, like the sultans of later times, sent an order for his death. His friends at Rome informed him of his impending fate, and he had therefore no other alternative than to declare his independence, proclaiming himself lieutenant of the senate and of the Roman people. But as soon as he was informed of the death of Nero, he assumed the title of emperor, being the first person not descended from the family of the Cæsars who reached that high dignity.

His previous life, and the habits which he had acquired, were little suited to the scene of corruption and debasement into which he now emerged. All ranks at Rome had become, by a long course of unrestrained license, so completely demoralized, that they could ill brook the sternness of an old military disciplinarian. He does not appear to have possessed any of the mental qualities of a statesman, nor was his previous education of a character likely to fit him for the position in which he now found himself placed. The affairs of the empire seem to have been chiefly directed by three favourites of very dissimilar characters; T. Vinius, his lieutenant in Spain, a man of unbounded avarice; Laco, prefect of the prætorian band, equally distinguished for his indolence and arrogance; and the freedman Icelus, who had all the follies of a foolish upstart. Every act of theirs was ascribed to the emperor, and all classes were equally dissatisfied with their proceedings. The soldiers were refused their usual largesses, and were deeply mortified by the reply of the emperor, *Legere se militem, non emere, consuesse.* The soldiers in Upper Germany openly refused to take the oath of allegiance to Galba; and at Rome Otho headed a conspiracy, which was embraced by too large a body not to prove successful against a man who stood nearly alone in Rome. He was assassinated in the seventh month of his reign, and in the seventy-third year of his age, *omnium consensu capax imperii nisi imperâsset,* as Tacitus pithily remarks. Suetonius, *Life of Galba;* Tacitus, *Hist.* i. 6–18, 49.

GALE, in nautical language, a term of various import. When the wind blows, but not so hard that a ship may not carry her top-sails a-trip, then they say it is a loom gale. When it blows very strong, they say it is a stiff, strong, or fresh gale. When two ships are near each other at sea, and, there being but little wind blowing, one of them finds more of it than the other, they say that the one ship gales away from the other.

GALE, *Dr John,* an eminent minister amongst the Baptists, was born at London in 1680. He studied at Leyden, where he early distinguished himself, and afterwards at Amsterdam, under Dr Limborch. He was chosen minister of the Baptist congregation at Barbican, where his preaching, being chiefly practical, was greatly resorted to by people of all persuasions. Four volumes of his sermons were published after his death, which happened in 1721. His *Reflections on Dr Wall's History of Infant Baptism* is the best defence of the Baptists ever published; and the reading of that performance induced Mr William Whiston and Dr Foster to become Baptists.

GALE, *Theophilus,* an eminent nonconformist minister, born in 1628. He was invited to Winchester in 1657; and continued a stated preacher there until the re-establishment of the church by Charles II. when he chose rather to suffer the penalties of the act of conformity, than to submit to it contrary to his conscience. He was afterwards engaged by Philip Lord Wharton as tutor to his sons, whom he attended to an academy at Caen in Normandy; and when this duty had been fulfilled, he became pastor of a congregation of private conventiclers in Holborn. He died in 1678, and is principally known by an elaborate work entitled the *Court of the Gentiles,* calculated to show that the Pagan philosophers derived their most sublime sentiments from the Scriptures.

GALE, *Dr Thomas,* a learned divine, born at Scruton, in Yorkshire, in the year 1636, was educated at Cambridge, and at length became professor of the Greek language in that university. He was afterwards chosen head master of St Paul's school, London, and was employed by the city in writing the elegant inscriptions on the monument erected in memory of the conflagration in 1666. In 1676 he was collated to a prebend in the cathedral of St Paul's; and was likewise elected a fellow of the Royal Society, to which he presented a Roman urn with its ashes. About the year 1697, he gave to the new library of Trinity College, Cambridge, a great number of Arabian manuscripts; and in the same year he was admitted as Dean of York. He died in that city in 1702, and was interred in the cathedral, where a monument, with a Latin inscription, was erected to his memory. He was a learned divine, an eminent historian, one of the best Greek scholars of his age, and maintained a correspondence with the most learned men abroad as well as at home. He published, 1. Historiæ Poeticæ Scriptores Antiqui, Paris, 1675, in 8vo; 2. Opuscula Mythologica, Ethica, et Physica, Cambridge, 1671, in 8vo; 3. Herodoti Historiarum libri x. London, 1679, in fol.; 4. Historiæ Anglicanæ Scriptores quinque, Oxford, 1687, in fol.; 5. Historiæ Britannicæ, Saxonicæ, Anglo-Danicæ, Scriptores quindecim, Oxford, 1691, in fol.; 6. Rhetores Selecti, and other works.

GALEN, CLAUDIUS, prince of the Greek physicians after Hippocrates, was born at Pergamus, in Asia Minor, about the year 131. His father was possessed of a considerable fortune, and not only well versed in polite literature, philosophy, astronomy, and geometry, but skilled in architecture. He instructed his son in the rudiments of learning, and afterwards procured him the greatest masters of the age in philosophy and eloquence. Galen having finished his studies under their care, chose physic as his profession, and chiefly studied the works of Hippocrates. Having at length exhausted all the sources of literature which were to be found at home, he resolved to travel, in order to converse with the most able physicians in other countries, intending at the same time to take every opportunity of inspecting on the spot the plants and drugs of the countries through which he passed. With this view he proceeded to Alexandria, where he staid some years; from thence he travelled into Cilicia, passed through Palestine, visited the isles of Crete and Cyprus, and made two voyages to Lemnos, in order to examine the Lemnian earth, which was then esteemed an admirable medicine. With the same view he went into Lower Syria, in order to obtain a thorough insight into the nature of the opobalsamum, or balm of Gilead; and having completed his design, he returned home by the way of Alexandria.

Galen had been four years at Pergamus, where his practice was attended with extraordinary success, when some seditious commotions induced him to repair to Rome, where he resolved to settle; but the proofs he gave of his superior skill, added to the respect shown him by several persons of elevated rank, created him so many enemies amongst his brethren of the faculty, that he was obliged to quit the city, after having resided there four or five years. He had not long returned to Pergamus, however, when he was recalled by the Emperors Aurelius and Verus. After their death, he retired to his native country, where he died about the year 200. He wrote in the Greek language, and is said to have composed two hundred volumes, which were unhappily burnt in the Temple of Peace. Galen was of a delicate constitution, as he himself asserts; but nevertheless, by his temperance and skill in physic, he arrived at a great age; for it was his maxim always to rise from table with some degree of appetite. He is justly considered as the greatest physician of antiquity next to Hippocrates; and he performed such surprising cures that he was accused of magic.

But without entering into any detail of the particular treatises written by Galen, it may be sufficient here to notice the different editions of his collected works. The Greek editions are those of Aldus and Asulanus, printed at Venice, 1527, in five vols. folio; and that of Hieronymus Gemusæus, printed at Basil, 1538, in the same form. The Latin editions are that of Paris, 1536, in folio, printed by Colinæus, and reprinted at Lyons in 1554, with additions and corrections by Frellonius; that of Basil, 1542, in folio, printed by Frobenius, and edited by Gemusæus; the editions published at the same place in 1549, 1550, and 1562, the last of which contains an able preface by Conrad Gesner; the edition of Venice, 1562, with the corrections of Rasario; ten editions published at Venice by the Juntas between 1541 and 1625, the ninth of which, printed in 1609, and the tenth, a reprint of the ninth, are the most correct; and, lastly, an edition printed at Venice in 1541–1545, by Farræus, in seven vols. 8vo, with the notes of Ricci. But the most elegant as well as most complete edition of Galen's works, both in

Greek and in Latin, is that which was published at Paris by René Chartier, 1639–1679, in thirteen vols. folio, which are ordinarily bound in nine or ten. This edition included the works of Hippocrates.

GALENIC, or GALENICAL, in *Medicine*, is the manner of considering and treating diseases, founded on the principles of Galen, or introduced by Galen.

Galenic is more frequently used as contradistinguished to *chemical*. The distinction of *galenical* and *chemical* was occasioned by a division of the practitioners of medicine into two sects, which happened on the introduction of chemistry into medicine. Then the chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice; and though this division into the two sects of Galenists and chemists has long since ceased, yet the distinction of medicines which resulted from it is still sometimes observed. Galenical medicines are those which are formed by the easier preparations of herbs and roots, by infusion or decoction, and by combining and multiplying ingredients; whilst those of chemistry derive their more remote virtues from elaborate preparations, as calcination, digestion, fermentation, and the like.

GALENISTS, a denomination given to physicians who practise, prescribe, or write, on the Galenical principles, and are opposed to the chemists.

GALENISTS, or *Galenites*, in *Ecclesiastical History*, a branch of Mennonites or Anabaptists, who adopt several of the opinions of the Socinians, or rather Arians, respecting the divinity of our Saviour. In 1664 the Waterlandians were divided into two parties, of which the one was called *Galenists*, and the other *Apostolians*. They are so denominated from their leader Galenus, a learned and eloquent physician of Amsterdam, who considered the Christian religion as a system which laid much less stress on faith than on practice, and who was for admitting into the communion of the Mennonites all those who acknowledged the divine origin of the books of the Old and New Testaments, and led holy and virtuous lives.

GALERICULUM was a cap worn both by men and women amongst the ancient Romans. It consisted of skin, which was so neatly dressed with human hair that the artificial covering could scarcely be distinguished from the natural. It was used by those whose hair was thin; and also by wrestlers, in order to keep their own hair from receiving any injury from the oils with which they were rubbed over before they exercised. It seems to have resembled our wigs.

GALIANI, FERDINAND, an eminent Italian writer, was born at Chieti, in the Neapolitan province of Abruzzo, on the 2d of December 1728. At eight years of age he was sent to his uncle at Naples, who was then first chaplain to the king. Here he received his elementary education, along with his brother Bernard, who was a few years older. In 1740, the uncle being obliged to go to Rome upon a political mission, he gave his two nephews in charge to the Celestine fathers, for the continuance of their studies; and accordingly, in the course of two years, they were instructed in philosophy, the mathematics, and other liberal sciences. The archbishop, on his return to Naples, received them back into his palace, where they studied law, and enjoyed the society and conversation of the most distinguished professors of the university of Naples. Ferdinand, who possessed great talents and vivacity, devoted himself with ardour to the study of history, antiquities, the belles lettres, and philosophy, and more particularly to political economy. At the age of sixteen he produced a *Memoir on the Coins of the period of the Trojan War*; and this early production first inspired him with the idea of his great work on money. He also translated Locke's treatise on *Money and Interest*. At the age of eighteen he undertook a work on the *Ancient History of the Navigation of the Mediterranean*; and in his great work, we find that he there made use of part of the materials which he had collected at this early age. A *jeu d'esprit*, which had nearly been attended with serious consequences, diverted him for some time from his graver studies. Having been charged by his brother Bernard to deliver, in his absence, a discourse in an academy of which he was a member, the president, looking only at the youth of Ferdinand, and being ignorant of his talents, would not permit him to proceed. The latter resolved to revenge himself in a manner that showed more spirit than prudence. It was the custom in this academy, as in several others, that when any great personage died at Naples, all the academicians published, in his praise, a collection of pieces in prose and verse. The executioner at Naples having died, Galiani seized the opportunity of turning the academy into ridicule. With the assistance of a friend, he composed, in the course of a few days, a collection of serious pieces on this event, which were ascribed to each of the members, and in which their peculiar style and manner were so well imitated, that one of them confessed he should have been himself deceived, if he had not been perfectly certain that he had not written the piece to which his name was subscribed. This malicious and witty little volume appeared in 1749, under the title of *Componimenti varj per la Morte di Domenico Jannacone, Carnefice della gran corte della vicaria, raccolti e dati in luce da Gian. Anton. Sergio Avvocato Napoletano.* This Sergio was the president of the academy. The publication was eminently successful, and excited a sensation which the authors had not foreseen; and as they became afraid of being discovered by the publisher, they went directly to the minister Tanucci, confessed the fact, and got off for the performance of some spiritual exercises.

Galiani soon effaced the impression made by this piece of youthful folly, by the publication of his *Treatise on Money*, which had employed the labour of several years. It appeared at Naples in 1750, when the author was only twenty-one. It was first published anonymously, and the author did not make himself known until the success of the work was decided. The Archbishop of Tarentum took this occasion to patronize him, and procured for him several benefices, which induced him to take orders. He afterwards travelled through the whole of Italy, was presented at the various courts, and found himself every where preceded by his reputation. He was well received by the pope and several of the Italian princes; he was admitted a member of some of the most celebrated academies; and he established a correspondence with many of the most eminent literary characters. His next publication was a treatise entitled *Della perfetta Conservazione del Grano*, written, with his usual elegance, for the purpose of recommending an ingenious machine, invented by his friend Intieri, for drying and preserving grain.

The active mind of Galiani was now engaged in investigating several scientific subjects, particularly connected with antiquities and natural history. He was the first who undertook to form a collection of the volcanic productions of Vesuvius; and he wrote a learned treatise upon this subject, which, however, was not printed until about fifteen years afterwards. He presented the manuscript to Pope Benedict XIV. along with the collection itself, which was arranged in seven boxes, according to the order of the treatise. The collection was placed in the Museum of the Institute of Bologna, where it still remains. In presenting this collection to the pope, Galiani had written upon one of the boxes, *Beatissime Pater, fac ut lapides isti panes fiant.* His holiness, understanding the hint, gave him the prebend of Amalfi, worth 400 ducats a year.

In the lifetime of his uncle, whom he lost in 1753, he enjoyed a benefice of 500 ducats, which conferred upon him the episcopal dignity, and another living worth 600 ducats. His funeral oration, on the death of his patron, Benedict XIV., who died in 1758, procured him a high character for eloquence, and was one of his works which he himself most esteemed.

Galiani was one of the members of the academy of Herculaneum, established by King Charles III. for the purpose of illustrating the remains of ancient art discovered among the ruins of that city; and he furnished several memoirs, which were inserted in the first volume of that magnificent work, the *Antiquities of Herculaneum.* With the other academicians who were engaged in this labour, Galiani enjoyed the royal bounty, in a pension of 250 ducats.

In the month of January 1759 he was appointed secretary of state and of the royal household, and, soon afterwards, secretary to the French embassy; and he arrived at Paris in the month of June following. Here his reception was exceedingly flattering, and his company was courted in all polite literary societies. The ambassador was the Count Cantillano, marquis of Castromonte, a Spanish nobleman, of much indolence and little talent. During the absence of the count on a six months' journey to Spain, Galiani remained *chargé d'affaires,* was presented to the king of France, and enjoyed all the advantages of his situation. He applied himself with great zeal and assiduity to the acquisition of a correct French style of writing; and about this time he commenced his learned and ingenious *Commentary on Horace,* of which the Abbé Arnaud inserted some extracts in the fifth, sixth, and seventh volumes of his *Gazette Littéraire* for 1765. About the commencement of that year Galiani had set out for Naples, for the purpose of taking the waters of Ischia. Long after his period of leave had expired, he was retained by the government, employed and consulted in several matters of importance, and at length appointed a member of the Supreme Council of Commerce. With this new title he returned to Paris; and about a year afterwards he obtained permission to travel for a few months in England, having been invited to that country by the Marquis of Caracciolo, who was then ambassador from the court of Naples at London. He returned through Holland to Paris, and soon afterwards wrote in French his celebrated *Dialogues sur le Commerce des Blés;* the style of which is so easy and elegant, that one would never suppose it to be the work of a foreigner. The manuscript was left in the hands of Diderot, and was published in 1770, with the date of London, and without the name of the author. The work excited great attention in France, and the best writers were loud and unanimous in their praise of it. Voltaire wrote to Diderot, who had sent him a copy, in the following terms: "The powers of Plato and Molière seem to be combined in the composition of this work. I have as yet only read about two thirds of it; and I expect the *denouement* of the piece with great impatience." The same author again praises the work in his *Questions sur l'Encyclopédie,* in the article *Bled ou Blé.*

Meanwhile, Galiani had returned to Naples, where, in addition to his office of member of the Council of Commerce, he received that of secretary to the same tribunal. These two situations brought him a revenue of 1600 ducats. In 1777 he was made one of the ministers of the *junto* of the royal domains, who had the charge of every thing connected with the private patrimony of the king; an office which added 200 ducats to his income. His partiality for the writings of Horace inspired him with the idea of a treatise *Des instincts ou des gouts naturels et des habitudes de l'homme, ou Principes du droit de la nature et des gens, tirés des Poësies d'Horace;* a work which he left nearly complete, but which has never been published. There is a life of Horace prefixed, much better and more complete than that which is inserted in the works of Algarotti. The project which he entertained of a dramatic academy induced him to attempt the composition of a comic opera, in a new and singular style. This was *The Imaginary Socrates,* of which he gave the plan to the poet Lorenzi, who put it into verse, and it was set to music by the celebrated Paesiello. The piece was performed with the greatest success throughout Italy, Germany, and even at St Petersburg. Galiani himself was passionately fond of music. He sung agreeably, and played well on the harpsichord. His library was select rather than numerous, and particularly rich in good editions of the Greek and Latin classics. He had also a considerable and very valuable cabinet of ancient coins and rare medals, engraved stones, cameos, and a few statues.

On the 8th of August 1779, a terrible eruption of Vesuvius spread the utmost dismay throughout Naples. For some time the press teemed with new and frightful descriptions of this phenomenon, and the ravages it occasioned; and the minds of the inhabitants were every day filled with fresh terror. In order to efface these disagreeable impressions, Galiani in a single night composed a piece on this eruption, in which he imitated very happily the style of an author who was well known in the city for his ridiculous weakness. This production was printed next day under the following title: *Spaventosissima descrizione dello spaventoso spavento, che ci spavento tutti coll' eruzione delli* 8 *di Agosto del corrente anno, ma (per grazia di Dio) duro poco, di D. Onofrio Galeota, poeta e filosofo all' impronto.* It was a very laughable piece on a very serious subject; and it had the effect of dispelling the melancholy ideas which had got possession of the minds of the people.

Galiani was very fond of the Neapolitan dialect, and took great pleasure in speaking it. In the same year he published anonymously, as was his custom, a work entitled *Del dialetto Napolitano,* in which he gave, for the first time, a grammar and history of this dialect, which he maintained was the primitive language of Italy; and shortly afterwards he composed a lexicon of the words peculiar to the Neapolitan tongue, which was begun to be printed in 1780; but the work was suspended, and has not since been resumed.

A work of a different kind soon afterwards engaged his attention. In the war which broke out in 1778, between England on one side, and France and Spain on the other, Naples and some other powers had remained neutral; but their rights, as they conceived, were not sufficiently respected by the belligerent parties. Numerous writings appeared throughout Europe on the rights and duties of neutrals; and, among others, Galiani produced a treatise in Italian, *On the Duties of Neutrals towards Belligerent Powers, and of the latter towards the former.* It was published at Naples in 1782, in 4to. In the same year he was appointed first assessor to the general council of finance; a situation which he accepted the more readily, as its duties were analogous to his other studies; but he refused to touch the salary. A few months afterwards, however, the king presented him with the abbacy of Scurcoli, which was worth 1200 ducats per annum, after deducting all charges and pensions. The office of assessor of economy in the superintendence of the crown funds, to which he was appointed in 1748, added to his public duties, and likewise increased his income. Meanwhile his health, which was naturally weak, declined daily. On the 13th of May 1785 he had an attack of apoplexy; and in order to prevent a return, he travelled the following year through Puglia. In 1787 he made a longer journey, and went as far as Venice, where he was well received by all the men of letters, as he was also at Modena by Tiraboschi, and by Cesarotti at Padua. On his return to Naples his health rapidly declined; and he died, quietly and resignedly, on the 30th of October 1787, at the age of fifty-nine.

Besides the works already mentioned, Galiani left behind him a variety of interesting manuscripts, which came into the possession of D. Francesco Azzariti, his heir, and many of which, it is said, well deserve publication. Among them are, 1. The Commentary on Horace, with the Life; 2. The Lexicon of Words peculiar to the Neapolitan Dialect; 3. A Poetical Translation of the Anti-Lucretius; 4. A Miscellaneous Collection of Poetical Pieces; 5. Several volumes full of facetious Letters, Novels, and Anecdotes; 6. His Epistolary Correspondence, which would form of itself a pretty voluminous collection. A part of it was published at Paris in 1818, in two vols. 8vo. (See the article GALIANI, by Ginguené, in the *Biographie Universelle*, tom. xvi.) (K.)

GALICIA, the largest province of Spain, and that which contains the greatest number of inhabitants. It is situated in the north-west corner of the peninsula. On the east it is bounded by Asturias and Leon, on the north and west by the ocean, and on the south by Portugal, from which it is separated by the river Mino. The extent of this province is 1330 square leagues, and the number of its inhabitants amounts to 1,585,419

On the coast the climate is mild and temperate; but, from the frequent and heavy rains which fall on the higher land, it is both humid and cold. Scarcely one sixth part of this province is cultivated; for though the natives are of robust frames and industrious habits, yet, as almost all the land belongs to either spiritual or municipal corporations, or is held in mayorazo or entail by private lords, the cultivators have no encouragement to improve, or are too poor to do so. They live in a state of great depression, are fed coarsely, and their houses and clothing bespeak great poverty. From the distress felt in their native province, they emigrate to every part of the peninsula, and procure subsistence by the lowest and severest kinds of labour. The term Galego is hence become synonymous with that of porter in every part of Spain. Wherever they are they seldom fail in regard for their native province; and they often return to it when they have saved enough in service to subsist upon. Their attachment to their families, especially to their aged and infirm relatives, is evinced by sending them pecuniary assistance; and they anxiously seek out employment for those of their younger relations and friends who may be inclined to exchange their condition for better food and more ample wages. Galicia contains more good harbours than the whole of the rest of the north of Spain, and it is crossed by various rivers, so that under a good system of government it might become a country of considerable commerce. One of the greatest hindrances to increasing prosperity is the want of good roads, bridges, and other means of communication. Some few advances towards these improvements had commenced, and would probably have succeeded, but for the war of the invasion, which put aside every object that did not immediately tend to the defence of the country. When fanaticism was more prevalent than it has recently been, the roads to the capital, Santiago, were frequented by numberless pilgrims from every part of Spain, and even France, who came to pay their vows at the shrine of St Jago. At that period roads, bridges, and hospitals were erected, but as the zeal for pilgrimages declined, these establishments decayed. Attempts to revive them were made in the reign of Ferdinand VI. about the year 1750, and roads were formed from Corunna to Santiago, from Corunna towards Madrid by Betanzos and Lugo, and from Santiago to Pontevedra, Puente de San Payo, and Tuy. These pass through the most sterile parts of the province. They are therefore less beneficial than one which was begun when the French entered Spain, which was designed to pass from Benevente to Vigo through Sanabria and Montemy, with branches connecting them with Santiago, Pontevedra, and Tuy. If even this plan is effected it will be of great advantage to all Galicia, but especially to the environs of Orensee, in which much wine is made, and where, for want of roads, the greatest calamity that can happen to the cultivators is a very productive grape season; for having no foreign vent, the price is so low that it does not pay the expense. It is estimated that the district of Orensee, after supplying its own inhabitants with wine, would be able to send to other markets 400,000 gallons annually.

Though Galicia is partially and imperfectly cultivated, it produces wheat and barley, but not in sufficient quantity for its consumption. It yields maize, potatoes, chestnuts, nuts, and wine. It feeds much cattle, especially pigs, from which hams and sausages are great articles of traffic with Castille, Andalusia, and the kingdom of Portugal; but having little or no oil, it receives that article from those parts in exchange. Hemp is grown, but not in sufficient quantity for the demand, which is supplied by the annual importation of about 1000 tons from the ports on the Baltic. Some flax and silk are raised in Galicia, but scarcely sufficient for the domestic consumption.

The plantations of oranges and lemons have gradually disappeared in Galicia, as well as in the neighbouring provinces of Asturias and Santander. In the middle of the seventeenth century both England and France were supplied with these delicious fruits from this province; but, as is supposed, from some change of climate, none are now grown in the north; and the whole commerce in these fruits is transferred to the southern provinces of the peninsula.

The manufactures of Galicia are leather, inferior woollen cloths and blankets, hats, linen, and some silks. Many families in some parts live by weaving, which is performed principally by the females, and there no house is to be found without a loom. The fisheries both on the coast and on the rivers employ many men, whilst their wives are weaving; and produce salmon, lampreys, eels, trouts, and other fish. These are pickled, and furnish a trade with the interior, though complaints are made that the demand is constantly decreasing. The same complaints are made of want of sale for sardinias, a most excellent sea-fish, which used, when caught, to be slightly salted, and conveyed in baskets to the mountainous districts, where no fish is to be had for keeping Lent and other periods of abstinence.

The sea-ports and fisheries of Galicia used to breed the best seamen of Spain, and the number of vessels of different classes once amounted to 1600; but the long wars in which the connection with France has involved Spain, whilst they have annihilated the royal navy, have reduced very considerably the merchant ships, and the seamen, who used to supply the king's fleet with dexterous sailors.

The rivers of Galicia are the Mino, which rises in the north, and after a course of fifty leagues, and receiving various tributary streams, enters the Atlantic Ocean at the boundary between Spain and Portugal; the Tamago, which rises in the province, and entering Portugal, empties itself into the Duero; and the Montemy, which likewise runs to the Duero.

The only mines, though the mountains are said to abound in iron, are some of tin, which were worked on account of the government; but in 1798 the working was abandoned, either because, from the negligence displayed in most royal works, it was too expensive, or the mines were not sufficiently rich in metal to induce a continuance of the operations. These mines are at Ciervas, one league from Montemy. This province contains 18,230 horses, 17,090 mules, 12,050 asses, 88,667 neat cattle, 764,509 sheep, 73,011 goats, and 142,236 swine. The bees produce, of honey 707, and of wax $347\frac{1}{2}$ cwt. The inhabitants make 200,000 dozen stockings, and 5,550,000 varas of linen.

GALILEE, once a province of Judæa, now of Turkey in Asia, was bounded by Mount Lebanon on the north, by the river Jordan and the sea of Galilee on the east, by the Chison on the south, and by the Mediterranean on the west. It was the scene of many of our Saviour's miracles; but the boundaries of the country are not now well known, nor even the places where many of the towns were situated.

GALILEANS, a sect of the Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, stirred up his countrymen against the edict of the Emperor Augustus, which had ordered an enrolment or taxation of all the subjects of the Roman empire. They pretended that God alone should be owned as master and lord, and in other respects they were of the opinion of the Pharisees; but as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart. As our Saviour and his apostles were of Galilee, they were suspected to belong to the sect of Galileans; and it was upon this principle, as St Jerome observes, that the Pharisees laid a snare for him, asking, whether it was lawful to give tribute to Cæsar, that if he denied it, they might have an occasion of accusing him.

GALILEO GALILEI, the founder of experimental science, was born at Pisa on the 15th of February 1564, being descended of a noble and ancient Florentine family, which, under the surname of Bonajuti, afterwards changed to that of Galilei, had filled distinguished offices in the state. His father, Vincenzo Galilei, was a man of considerable talent and learning, with a competent knowledge of the mathematics, and particularly devoted to the study of music, on the theory and practice of which he published several treatises. Vincenzo had three sons, Galileo, Michel Angelo, and Benedetto, and the same number of daughters, Giulia, Virginia, and Livia; but he was not opulent, and being burdened with a numerous family, was unable to provide for them expensive instructors. The subject of this notice exhibited early symptoms of an active and original mind, and even in his childhood showed a singular aptitude for mechanical contrivances, imitating with infinite address all sorts of machines, inventing new ones, or when, as often happened, he wanted the necessary materials for constructing these, adding new pieces to old ones. It is worthy of observation, that the boyhood of his great follower, Newton, whose genius in many respects closely resembled his own, was marked by a similar talent. Galileo commenced his literary studies at Florence, where his family resided; but, for the reason already stated, his masters were of the humblest kind. Knowing the disadvantages of his situation, however, Galileo resolved to supply by industry the want of better opportunities; and he applied with so much assiduity to the study of the classic models, that he soon laid the foundations of that extensive and solid literature to which he was afterwards indebted for the purity of his language and the elegance of his writings. His leisure hours were applied to the cultivation of music and drawing, in both of which arts he excelled. For the former he inherited his father's talent, which he displayed by performing skilfully on several instruments, especially the lute; and during the whole of his life this continued to be his favourite recreation amidst more serious pursuits. In the latter, which he had at one time thoughts of cultivating as a profession, he acquired so perfect a taste, that eminent contemporary artists did not scruple to own their obligations to him for his counsel and suggestions. Such was Galileo at the age of eighteen, when his father, becoming daily more sensible of the extent of his genius, determined, at whatever sacrifice, to give him the advantage of an university education. In 1581 he accordingly commenced his academical career in the university of Pisa, which he entered with the intention of studying medicine, from the profession of which his father hoped that he might one day procure an easy and honourable subsistence.[1] And, that he might not lose any kind of instruction which was to be obtained, he attended a course of peripatetic philosophy, such as it was then taught, in addition to that of medicine. But, called by the predestination of genius to unveil to mankind those wonders of nature, which their fanatical confidence in the opinions of Aristotle prevented them from seeing even when revealed, he could not bring himself to assent without conviction, nor to admit the authority of a master in questions which reason and experiment ought alone to decide. Actuated by this spirit, he several times ventured, in the academical discussions, to combat the firmest supporters of the Aristotelian dogmas, and in consequence he obtained the reputation of possessing an obstinate and contradictory disposition; for men do not easily reconcile themselves to the subversion of opinions, the stability of which they have long been accustomed to consider as incapable of being shaken; and hence the partisans of Aristotle found as great difficulty in doubting as Galileo did in admitting the authority of that master. It is not a little remarkable that, some years later, Descartes commenced in France, as Bacon did in England, the same war which Galileo had so boldly declared at Pisa; thus proving that the great regenerative efforts of the human mind are inevitably brought on by the force of circumstances and the natural progress of ideas, and that the men of genius who attach their names to these memorable revolutions, are themselves carried onward by their age, and precede it only by a few steps.

It was at this period, 1582, when he had scarcely completed his eighteenth year, that Galileo made the first and perhaps the finest of his discoveries. Happening one day to be in the metropolitan church of Pisa, he remarked the regular and periodic movement of a lamp suspended from the roof of the cathedral; he also observed the equal duration of its oscillations, whether great or small; and this he confirmed by repeated experiments. Having satisfied himself as to the phenomenon itself, he immediately perceived the use to which it might be applied for the exact measurement of time; and this idea having remained in his mind, he employed it fifty years afterwards (in 1633) for the construction of a clock intended for astronomical observations. In what manner this instrument was constructed, does not exactly appear; but it seems certain that it was employed for the purpose stated; and this, in our opinion, is sufficient to entitle Galileo to the honour of having been the first to make an application which afterwards became of so much importance to astronomy; for Huygens, who, in truth, rendered it incomparably more perfect, by employing the pendulum as the regulator of clocks, and not as the motive power alone, did not publish his researches on this subject until about the year 1658.

At the time of which we are here speaking, Galileo had no knowledge of the mathematics, nor even the least desire to learn them, not conceiving in what respect triangles and circles could conduce to the advancement of philosophy. The study of geometry was then at a very low ebb, not only in Italy, but in every country of Europe. Commandine, it is true, had recently revived a taste for the writings of Euclid and Archimedes; Vieta, Tartalea, and others had made considerable progress in algebra; and Guido Ubaldi and Benedetti had done something towards establishing the principles of statics, the only branch of mechanics as yet cultivated. But, with these exceptions, the application of mathematics to the phenomena of nature was scarcely thought of. Galileo's first inducement to acquire a knowledge of geometry arose from his partiality for music and drawing; he had heard his father repeatedly state, that these arts, of which he was passionately fond, had their principles in the relations of numbers and of position taught by the mathematics; and he now entreated to be instructed in a subject which promised to unfold to him the true theory of his favourite pursuits. But his father, apprehensive that a study which so strongly attaches those who take pleasure in it would diminish his zeal for medicine, told him to wait until he had completed his course. Galileo, however, was not satisfied; and as Ostilio Ricci, professor of mathematics in the university, frequently visited at his father's house, he besought this person to give him secretly some lessons in geometry. The professor consented, after having privately asked and obtained the consent of the father. But the young man had no sooner entered into that field of investigation for which nature had destined him, than his mind became engrossed by the pleasure he felt in the certain and entire possession of truth; from that moment medicine and philosophy were abandoned for Euclid; and all the efforts and remonstrances of his father, who desired to recall him to pursuits which he thought more useful, and even went so far as to prohibit him from holding any intercourse with Ricci, proved unavailing. The impulse had been given, and all attempts to counteract it were fortunately useless. Galileo had learned enough to study alone. He accordingly continued in secret the perusal of Euclid, at the same time keeping open beside him a Galen or an Hippocrates, in order to conceal the favourite book when his father entered. Having thus by stealth advanced as far as the sixth book, and being transported with the utility which he discovered in the science of geometry for giving force and method to the understanding, he resolved to avow his progress to his father, and entreat the latter no longer to oppose the decided bent of his mind. Vincenzo, perceiving that he was born for the mathematics, yielded to the irresistible predilection of his son, and permitted him to enter freely upon those speculations to which he thenceforward devoted all the energies of his highly-gifted intellect.

---

[1] In the matriculation lists of Pisa he is styled Galileo, the son of Vincenzo Galilei, a Florentine, scholar in arts. His entry is dated the 5th November 1581.

Having thus abandoned medicine, Galileo read with avidity the works of the ancient geometers, and then proceeded to study the treatise of Archimedes on floating bodies, which greatly delighted him. He now sought to multiply the applications of the method employed by the illustrious ancient in determining the proportions of an alloy of silver and of gold by successive weighings in water and in air; and for this purpose he invented an instrument similar in its uses to that which was afterwards called the hydrostatic balance. This invention, joined to his previous discovery respecting the movement of oscillation, and his new and free method of discussing subjects in philosophy, had already procured him considerable reputation, when he formed a connection with the Marquis Guido Ubaldi, then one of the most learned mathematicians of Italy. At the suggestion of this distinguished person, Galileo applied himself to consider the position of the centre of gravity in solid bodies; a choice of subject sufficiently indicating the estimate which Ubaldi had formed of his powers, considering that the question was one on which Commandine had recently written, and which at that time engaged the attention of geometricians of the highest order. Galileo, however, discontinued his researches on meeting with Valerio's treatise upon the same subject; but Ubaldi was so much struck with the genius displayed in the essay which Galileo presented to him, that he introduced the young geometer to his brother the Cardinal del Monte, who again warmly recommended him to John de' Medici and the Grand Duke Ferdinand of Tuscany, as a person of the highest promise. These illustrious personages gave him a most favourable reception, and soon afterwards bestowed on him the chair of mathematics in the university of Pisa, although he had as yet scarcely completed his twenty-fifth year.

Excited by this distinction, Galileo neglected nothing calculated to justify the preference which had been given him; and conceiving that a knowledge of the laws of motion is the basis of all solid study of nature, he undertook to establish them, not by hypothetical reasonings, as was the practice in the schools, but by real experiments. He thus demonstrated that all bodies, whatever be their nature, are equally affected by gravity; and that, if the spaces through which they descend in equal times are different, this depends on the unequal resistance opposed to them by the air, according to their different volumes. This important proposition Galileo completed long afterwards, in a work entitled *Dialoghi delle Scienze Nuove*, in which he established the true theory of uniformly accelerated motion. The novelty and beauty of his first experiments, performed before an immense concourse of spectators, excited great enthusiasm. But they at the same time embittered the animosity of the partisans of the ancient philosophy, who, seeing their whole science attacked, sought to destroy the innovator in the opinion of persons in power, and at length succeeded in raising against him such a host of annoyances and persecutions, that, in 1592, he was obliged to resign his chair at Pisa. He returned to Florence without employment, but durst not present himself in the house of his father, who had already made so many sacrifices on his account. He had the good fortune, however, to obtain from Guido Ubaldi a letter of recommendation to an opulent gentleman of Florence, of the family of the Salviati, who received him with extreme kindness, and afforded him the means of prosecuting his discoveries, until he could find some employment. With a view to serve him, Salviati also made him known to a Venetian nobleman of the name of Sagredo; an enlightened and influential man, who soon afterwards obtained for the youthful philosopher the chair of mathematics at Padua, which was conferred on him for six years. It was in gratitude for these seasonable benefits that Galileo gave the names of Sagredo and Salviati to the two interlocutors in his dialogues who support the true philosophy.

In his new situation, where he enjoyed greater freedom than he had done at Pisa, Galileo continued, with still more brilliant success, both his public lessons and his experimental researches. He constructed, for the service of the state, various machines of great utility; and he wrote for his pupils treatises on gnomonics, mechanics, spherical astronomy, and even fortification, according to the usage of the age, when many things were united which the progress of knowledge has since separated. In 1597, he invented the thermometer[1] and the proportional compass or sector, which he called the military compass, because he had principally intended it for the use of engineers. In 1599, his commission having expired, the senate renewed it for another six years, with an increase of salary, which Galileo repaid to the republic by new discoveries. In 1604, an unknown star of extraordinary brightness having suddenly appeared in the constellation of Serpentarius, Galileo demonstrated, by his observations, that this body was placed far beyond what the peripatetics called the elementary region; nay, that it was much more remote than all the planets, contrary to the formal and infallible opinion of Aristotle, who maintains that the heavens are incorruptible and free from all mutation. He also made researches on natural magnets, and succeeded in considerably augmenting their power by means of capping or casing them. His commission as professor was renewed a second time in 1606, with additional advantages, for which he testified his gratitude, as before, by increased diligence in the prosecution of his discoveries. But envy, which had never lost sight of him, exerted herself to disturb that peace which is so necessary to the successful pursuit of science. In 1604, on the occasion of his researches respecting the new star, he had been grossly abused by one Baltasar Capra of Milan. This man had the audacity to publish a Latin treatise on the proportional compass, in which he represented himself as the real inventor of that instrument; but the calumny was so gross that nobody was deceived by it; Galileo confounded his adversary, and the work of Capra was prohibited as a defamatory libel. Nor was this the only instance in which he had to vindicate his right of property in his own inventions. He frequently found himself ill recompensed for the readiness with which he communicated the results of his investigations; but he always raised himself by new discoveries, far above these disgraceful attempts to appropriate the fruits of his genius.

---

[1] The original idea of this instrument belongs to the Greek mathematician Hero; and even Santorio, who has been named by Italian writers as the inventor, and, at one time, claimed the invention as his own, refers it to him. In 1613, Sagredo, who has been

The year 1609 was signalised by a discovery on the part of Galileo, which forms one of the most solid foundations of his glory. In the month of April or of May, a rumour was circulated in Venice that a Dutchman had presented to Count Maurice of Nassau an instrument, by which means distant objects appeared as if they were near at hand. On this slight and cursory hint Galileo immediately applied himself to discover whether the thing was possible, conformably with the passage of the luminous rays through spherical glasses of various forms. Some attempts made with lenses which he had at hand produced the desired effect; and next day he gave an account of his success to his friends, which, in fact, was nothing less than the invention of the telescope. A short time afterwards he presented several of these instruments to the senate of Venice, accompanied with a description in which he unfolded the immense consequences for nautical and astronomical observations which would certainly result from the discovery; and in recompense of his ingenuity his commission as professor was continued for life, with an allowance of salary triple that which he had previously received. Galileo neglected nothing calculated to evince his gratitude, or to add to the claims which had merited these favours. Indefatigable in his researches, he invented the microscope; he also improved his telescope, and soon brought it to a state fit to be applied to the observation of the heavens. He then perceived what as yet no mortal eye had ever seen; the surface of the moon, like that of the earth, bristled with high mountains and ploughed with deep valleys; Venus, presenting, like the moon, phases which prove her rotundity; Jupiter environed with four satellites, who accompany him in his course; the milky way; the nebulæ; in a word, the whole heavens bespangled with a countless multitude of stars too small to be even perceived by the naked eye. It is more easy to conceive than describe the surprise and delight which the first view of so many wonders must have inspired him withal, as well as the admiration which they could not fail to produce when they were known. A few days having sufficed to pass them in review, he hastened to announce his observations to the world in a publication entitled *Nuncius Sidereus*, or Celestial Courier, which he dedicated to the princes of Medici, and which he continued at intervals, in proportion as he discovered new objects. He also observed that Saturn sometimes appeared under the form of a simple disc, and sometimes with two appendages which seemed two small planets; but it was reserved for another astronomer (see HUYGENS) to demonstrate that these appearances were produced by the ring with which Saturn is surrounded. Galileo also discovered moveable spots on the globe or disc of the sun, whom the peripatetics had declared incorruptible, and did not hesitate from these to infer the rotation of that planet. He remarked that feeble light which, in the first and last quarter of the moon, renders visible, by means of the telescope, the part of her disc which is not then directly enlightened by the sun; and he concluded rightly that this effect was owing to the light reflected towards the moon by the earth. The continued observation of the spots of the moon satisfied him that that planet always presents nearly the same aspect; but in these he nevertheless recognised a species of periodic oscillation, to which he gave the name of libration, the exact laws of which were afterwards made known by Dominic Cassini. In a word, not less profound in following new truths to their consequences than subtile in discovering them, Galileo perceived the use to which the motions and eclipses of the satellites of Jupiter might be turned for the measure of longitudes; and he even undertook to make a sufficient number of observations of these stars to enable him to construct tables for the use of navigators.

After so many and so admirable discoveries, we have good reason to be astonished that any one should dream of denying to Galileo the invention of the telescope, with which he had made them; as if, in such a case, the inventor was not he who, guided by certain rules and by great views, knew how to perform wonders with that which chance had thrown rude and unfashioned into incapable hands. If he who, in Holland, accidentally joined two glasses of unequal curvature, was really the inventor of the telescope, why then did he not turn it towards the heavens, the most beautiful and sublime application of that instru-

---

already mentioned as the friend of Galileo, writes to him in the following terms :—"I have brought the instrument which you invented, into several convenient forms, so that the difference of temperature between two rooms is seen as far as a hundred degrees." The date of this communication, which incidentally establishes the invention of Galileo, is anterior to the claims of Santorio, and also to those of Drebbel, a Dutch physician, who obtained, and still preserves in Germany, the honour of having invented this instrument. Another testimony may be added. In 1638, Castelli wrote to Cesarini that he remembered an experiment shown to him more than thirty years before by Galileo, who took a small glass bottle, about the size of a hen's egg, the neck of which was twenty-two inches long, and as narrow as a straw. "Having well heated the bulb in his hands, and then introduced its mouth into a vessel containing water, he withdrew his hand from the bulb, on which the water rose in the neck of the bottle more than eleven inches above the level of that in the vessel; and this principle he employed in the construction of an instrument for measuring heat and cold." Galileo's thermometer, therefore, consisted merely of a glass tube ending in a bulb, the air in which, being partly expelled by heat, was replaced by water from a glass in which the open end of the tube was immersed; and the different degrees of heat were indicated by the expansion of the air which still remained in the bulb, so that the scale would be the reverse of that now in use, as the water would stand at the highest level in the coldest weather. In other words, it was a compound of the barometer and thermometer.

ment? Why did he leave to Galileo the happiness and glory of overturning, in the eyes of all, ancient prejudices, of consolidating by the clearest proofs the system of Copernicus, and of aggrandising the celestial spaces beyond all that the imagination could have conceived? But however this may be, it is easy to comprehend to what a height so many and so great discoveries must have raised the views of Galileo; he perceived all the consequences which resulted from them relatively to the constitution of the universe; and, indeed, how could they escape him who, having taken nature as his guide, had, during his whole life, preserved his mind open to her impressions?[1] He concealed none of these high consequences, which formed as it were the soul of his writings and conversation; and he considered himself as henceforth entitled to despise errors too gross to be honestly maintained.

But, unfortunately for himself, he was no longer under the protection of Venice. Yielding to the instances of the Grand Duke of Tuscany, who had named him mathematician extraordinary, and loaded him with favours, he had quitted Padua, where he enjoyed the utmost freedom, for Florence, where such a thing as liberty was scarcely known. Honoured by the senate of Venice, and united by the ties of friendship with several of the most distinguished senators, he could publish his opinions without danger to himself as long as he remained within the territories of that state. But, in the end, experience proved that he could have no such security at the court of a prince, obliged at least to keep up appearances with the court of Rome. Besides the number of envious persons whom his great merit had exasperated against him, his discoveries made to him enemies of all those who had hitherto taught the ancient doctrines; and of these persons by far the greater part were ecclesiastics. Accordingly, some spread it abroad that his discoveries in the stars were pure visions, comparable only to the voyage of Astolphus; others affirmed that they had had the telescope in their possession during entire nights, and that they had seen nothing of all that which Galileo had announced; and a preacher was found who, malicious enough to convey a dangerous allusion in a pun, took as his text the words of the Gospel, *Viri Galilæi, quid statis adspicientes in cœlum?* It was thus that the countrymen of Copernicus had publicly ridiculed him on the stage; and it was thus that, at a later period, the reformed of Holland persecuted Descartes, who had taken refuge amongst them.

But the most certain method of reaching Galileo was to begin by prohibiting the doctrine of Copernicus, which he supported and propagated with so much distinction. This was accordingly effected by representing it as contrary to Scripture, and denouncing it to the holy see. Galileo endeavoured in vain to allay the storm, by publishing, in 1616, a letter addressed to the Grand Duchess of Tuscany, in which he undertook to prove theologically, and by reasons deduced from the Fathers, that the terms of Scripture might be reconciled with his new discoveries respecting the constitution of the universe. But this production only afforded a new handle to his adversaries, who maintained that he had rested his defence on an opinion which was itself erroneous in point of doctrine. He was cited to appear personally at Rome, and constrained to repair thither to defend himself. But neither the arguments which he urged in support of his opinions, nor the justice which they were forced to render to his knowledge, his merit, and even his catholicity, could prevent an assembly of theology, named by the pope, from coming to the following conclusion: "To maintain that the sun is placed immoveable in the centre of the world, is an opinion absurd in itself, false in philosophy, and formally heretical, because it is expressly contrary to the Scriptures; to maintain that the earth is not placed in the centre of the world, that it is not immoveable, and that it has even a daily motion of rotation, is also an absurd proposition, false in philosophy, and at least erroneous in point of faith." Confounded at this deliverance, Galileo employed all the arguments which the truth suggested to him in defence of a doctrine which his observations had rendered indubitable; but his efforts were unavailing; his reasonings were disregarded; and as he had not showed sufficient deference to the decision of the holy office, he was personally interdicted from professing in future the opinion which had just been condemned.[2]

---

[1] "The interpreter of the works of nature is experiment," says Leonardo da Vinci; "that is never wrong: it is our judgment which is sometimes deceived, because we expect results which experiment refuses to give. We must consult experiment, and vary the circumstances, till we have deduced general rules, for it alone can furnish us with them. But, it will be asked, what is the use of these general rules? I answer, that they may direct us in our inquiries into nature and the operations of art. They keep us from deceiving ourselves and others, by promising ourselves results which we can never obtain." (Venturi, *Essai sur les Ouvrages de Leonardo da Vinci.*)

[2] It has been contended that the treatment which Galileo experienced on this and a subsequent occasion was caused, not by his maintaining the true system of the world, which, in the above declaration, is formally condemned as "false in philosophy and erroneous in faith," but solely by his persisting in the endeavour to prove that the Scriptures were reconcilable with the Copernican theory. "Ce philosophe (Galileo)," says Bergier, "ne fut point persécute comme bon astronome, mais comme mauvais théologien. C'est son entêtement à vouloir concilier la Bible avec Copernic, qui lui donna les juges. Mais vingt auteurs, surtout parmi les Protestans, ont écrit que Galilée fut persécuté et imprisonné pour avoir soutenu que la terre tourne autour du soleil, que ce système a été condamné par l'Inquisition comme faut, erroné, et contraire à la Bible." (*Encyclopédie Méthodique*, art. *Sciences humaines*, Paris, 1790.) This is a complete misrepresentation of facts known to every one. So far was Galileo from persisting in an attempt to reconcile the Bible with Copernicus, that he regarded this as a matter altogether indifferent, and indeed beside the real question. "I am inclined to believe," says he in his letter to the Grand Duchess of Tuscany, "that the intention of the sacred Scriptures is to give mankind the information necessary for their salvation, and which, surpassing all human knowledge, can by no other means be accredited than by the mouth of the Holy Spirit. But I do not hold it necessary to believe that the same God who has endowed us with senses, with speech, and with intellect, intended that we should neglect the use of these, and seek by other means for knowledge which they are sufficient to procure us; especially in a science like astronomy, of which so little notice is taken in the Scriptures, that none of the planets, except the sun and moon, and once or twice only Venus, under the name of Lucifer, are so much as named there. This therefore being granted, I think that in the discussion of natural problems we ought not to begin at the authority of texts of Scripture, but at sensible experiments and necessary demonstrations; for from the divine word sacred Scripture and nature did both alike proceed; and I conceive that, concerning natural effects, that which either sensible experience sets before our eyes, or necessary demonstrations prove unto us, ought not upon any account to be called in question, much less condemned, upon the testimony of Scripture texts, which may under their words couch senses seemingly contrary thereto." Can any thing be more explicit than the contradiction of the assertion of Bergier contained in these words? Is there any evidence here of Galileo's alleged "entêtement à vouloir concilier la Bible avec Copernic?" But the philosopher proceeds in continuation: "Again, to command the professors of astronomy that they of themselves should see to the confuting of their own observations and demonstrations, is to enjoin a thing beyond all possibility of being done; for it is not only to command them not to see that which they do see, and not to understand that which they do understand, but it is to order them to seek for and find the contrary of that which they happen to meet with. I would entreat these wise and prudent fathers that they would with all diligence consider the difference which exists between opinionative and demonstrative doctrines; to the end that, well weighing in their own minds with what force necessary inferences urge

Galileo returned to Florence in 1617, and resumed, with what grief may be easily imagined, the course of his astronomical labours. But his love for these sublime truths, of which he considered himself as the depositary, increasing in proportion to the efforts made to extinguish it, he undertook to silence, if he could not persuade, his adversaries, by collecting into a body all the physical proofs of the motion of the earth and the constitution of the heavens; and during sixteen entire years he was engaged in this work. All that the finest genius could imagine in point of ingenuity, or the purest taste admit in point of elegance, he employed to render the truth attractive. But it is not a learned treatise which he presents to us as the fruit of his labour and talents; it is merely a continued simple dialogue between two of the most distinguished personages of Florence and Venice, and a third interlocutor, who, under the name of Simplicius, undertakes to re-produce the "invincible arguments" of the peripatetics; and each perfectly sustains the part assigned to him. The two men of the world possess instruction, without system, and without prejudices; they discuss, examine, propose doubts, and only yield to cogent reasons. The good Simplicius, on the other hand, is altogether scholastic; he neither understands nor desires to comprehend any thing but Aristotle; he judges things true or false according as they are conformable or opposed to the assertions of his master; the least pleasantry on this subject is insupportable to him, and he yields not to any kind of conviction. The style of each of the interlocutors is also perfectly adapted to his character, without ceasing however to preserve, amidst these shades of distinction, an exquisite elegance, united with the most felicitous choice of expressions.

But if great genius was required for the composition of such a work, equal address was necessary to obtain permission to publish it; and this Galileo undertook to procure even in Rome itself. In 1630 he proceeded to that city, and having waited on the master of the sacred palace, boldly presented his work as a collection of new scientific fancies, at the same time requesting him to have the goodness to examine it scrupulously, to retrench whatever might appear to him exceptionable, and indeed to criticise it with the greatest severity. The prelate, not suspecting any thing, read it once and again; handed it to one of his colleagues for his opinion; and, not seeing any thing reprehensible in the work, set his hand to the most ample approbation of its contents. But the permission thus obtained was not sufficient; for, in order to profit by it, the work must be printed at Rome; and the numerous enemies of Galileo in that city would not have failed to explode the mine which the philosopher was himself charging to blow them up. On the pretext of some difficulty of communication between Rome and Florence, occasioned by a contagious distemper which then prevailed, Galileo accordingly wrote to the master of the sacred palace, soliciting permission to print his work at Florence, on the condition of having it again examined in that city. But the prelate, who perhaps began to suspect some deception, made difficulties; pointed out to Galileo a new censor; and demanded to see the approbation which he had previously given, in order, as he said, to revise the terms in which it had been conceived. With this request Galileo could not refuse to comply; but the prelate having once got hold of the document, refused to restore it, or to give any answer in explanation of his conduct; so that Galileo, after making every effort to recover it, and even causing it to be demanded by the ambassador of Tuscany, was compelled to abandon the pursuit as hopeless; and, contenting himself with the approbation of the censor of Florence, which he now managed to obtain, he published his work in 1632.

To shield himself as much as possible from prosecution, he however imagined the singular expedient of presenting his dialogues to the public as an apology for the judgment of Rome, by which the doctrine of Copernicus had been condemned. "Some years ago," says he, in the commencement of the introduction, which is addressed to discreet readers, "a salutary edict was promulgated at Rome, which, in order to obviate the perilous scandals of the age, enjoined an opportune silence as to the Pythagorean opinion of the earth's motion. There were not wanting persons who rashly asserted that this decree had originated, not in a judicious examination, but in ignorance and passion; and complaints were even heard that councillors unexperienced in astronomical observations should have attempted by hasty prohibitions to clip the wings of speculative minds. When I heard these rash lamentations, my zeal would not suffer me to remain silent; and being fully informed in regard to that most prudent determination, I thought it proper to appear publicly on the theatre of the world as a witness of the actual truth. I happened at that time to be in Rome; I was admitted to the audiences, and enjoyed the approbation, of the most eminent prelates of that court; nor did the publication of the decree pass without my receiving some previous intimation of the circumstance.[1] Wherefore it is my intention, in this present work, to show to foreign nations that as much is known of this matter in Italy, and particularly in Rome, as ultramontane diligence ever formed any notion of; and, collecting together all my own speculations on the Copernican system, to give them to understand that the knowledge of these preceded the Roman censures, and that from this country proceed not only dogmas for the salvation of the soul, but also ingenious discoveries for the gratification of the understanding. With this object in view, I have taken up in the dialogue the Copernican side of the question, treating it as purely a mathematical hypothesis, and endeavouring in every artificial manner to represent it as having the advantage, not over the opinion of the stability of the earth absolutely, but according to the manner in which that opinion is defended by some who indeed profess to be peripatetics, but retain only the name, and are contented without improvement to worship shadows, not philosophizing with their own reason, but only from the recollection of four

---

us, they might the better assure themselves that it is not in the power of professors of demonstrative sciences to change their opinions at pleasure, and adopt first one side and then another; and that there is a great difference between commanding a mathematician or a philosopher, and the disposing of a lawyer or a merchant; and that the demonstrated conclusions touching the things of nature and of the heavens cannot be changed with the same facility as the opinions are what is lawful or not in a contract, bargain, or bill of exchange. Therefore, first let these men apply themselves to examine the arguments of Copernicus and others, and leave the condemning of them as erroneous and heretical to whom it belongs; yet let them not hope to find such rash and precipitate determinations in the judicious and holy fathers, or in the absolute wisdom of him who cannot err, as those into which they suffer themselves to be hurried by some particular affection or interest of their own. In these and such other positions, which are not directly articles of faith, no man doubts but his holiness has always an absolute power of admitting or condemning them; but *it is not in the power of any creature to make them to be true or false, otherwise than of their own nature and in fact they are.*"

[1] Delambre, whose prejudice against Galileo is as unreasonable as his partiality to Kepler is marked, quotes this sentence as an instance of mis-statement of facts on the part of Galileo. With all his acknowledged ability, the historian of astronomy does not seem to have perceived, what must be obvious to almost every reader, that the whole passage is ironical, and that in the very sentence which he has cited there lurks a bitter sarcasm. (*Histoire de l'Astronomie Moderne*, tome i. p. 666.)

principles imperfectly understood." Any one who peruses a few pages of the dialogues will be at no loss how to interpret this declaration, nor will he feel any surprise that those whom Galileo here pretended to vindicate should have evinced but little gratitude for such a justification. But what can scarcely be imagined now, is the fury which the appearance of this work excited amongst the theologians of Rome, almost all of whom were ardent peripatetics. In vain did Galileo attempt to escape by alleging that his book had been submitted to the judgment of the holy see; in vain did he, as a last resource, protest that his only object had been to expound, in a philosophical manner, the two systems of Ptolemy and Copernicus. His enemies would not suffer any such excuse to be listened to. Still there remained to him some hope, founded upon the personal esteem of Pope Urban VIII., who, on a former occasion, had given him a most gracious reception, and had even paid his astronomical discoveries the compliment of celebrating them in bad verse; but the holy father having been persuaded that Galileo had intended to represent him under the character of Simplicius, his wounded self-love rendered his severity inexorable.[1] Notwithstanding the intercession of the Grand Duke of Tuscany, and the earnest solicitations which this prince caused to be made by his ambassador, the work of Galileo was delated to the Inquisition, and the author himself ordained to appear before that formidable tribunal.

The power of Rome was then supreme; it was necessary to obey. Neither the infirmity of his health, nor the pain he suffered from a rheumatic complaint which afflicted him, could procure an exemption from that sorrowful journey. This was in 1633, Galileo being then in the sixty-ninth year of his age. "I arrived at Rome," says he, in one of his letters, "on the 10th February, and was remitted to the clemency of the Inquisition, and of the sovereign pontiff, Urban VIII. who had some esteem for me, although I could not compose epigrams or write little amatory sonnets. I was put under arrest in the delicious palace of the Trinità de' Monti, the residence of the ambassador of Tuscany. Next day I received a visit from Father Lancio, commissary of the holy office, who took me with him in his coach. By the way he put to me a number of questions, and showed a great desire that I would repair the scandal which I had given to all Italy by maintaining the opinion of the motion of the earth; and to all the mathematical reasons which I could oppose to him, he could make no other answer than this: *Terra autem in æternum stabit, quia terra in æternum stat.* In discoursing thus we arrived at the palace of the holy office. I was presented by the commissary to the assessor, with whom I found two religious Dominicans, who civilly informed me that I would be permitted to explain my reasons before the congregation, and that afterwards I should be heard as to my grounds of excuse, if I was found guilty. The Thursday following I appeared before the congregation, and applied myself to the exposition of my proofs. But, unfortunately for me, they were not apprehended; and, notwithstanding all the pains I took, I could not succeed in making myself understood. My reasonings were cut short by bursts of zeal; they spoke to me only of the scandal which I had occasioned; and always opposed to me the passage of Scripture on the miracle of Joshua as the victorious piece of my process. This brought to my recollection another passage where the language of the sacred book is evidently conformable to popular ideas, since it is said that *the heavens are solid, and polished like a mirror of brass.* This example appeared to me one in point to prove that the expression of Joshua might be similarly interpreted; and the consequence seemed to me perfectly just. But no regard whatever was paid to it; and all the answer I received consisted of shrugs of the shoulders."[2] On the 30th of April Galileo was sent back to the residence of the ambassador, with a prohibition not to go beyond the *enceinte* of the palace, but with permission to walk freely in the extensive gardens attached to it. On the 22d of June he was again brought before the tribunal to hear the sentence read, and pronounce the abjuration dictated to him, according to which the venerable philosopher was made to say, "I abjure, curse, and detest the error and heresy of the motion of the earth," &c. and to promise that he would never more in future say or assert any thing, verbally or in writing, importing "that the sun is the centre of the world, and immoveable; and that the earth is not the centre of the world, and moveable." This expiation being completed, his dialogues were prohibited; he was condemned to suffer imprisonment for an indefinite period; and, as a salutary punishment, he was ordained to recite once a week for three years, the seven penitential psalms. Such was the unworthy recompense of one of the greatest geniuses that has ever enlightened humanity.[3]

---

[1] See Letter written by Galileo from Acastri, 26th June 1636, and cited by Targioni-Tozzetti in his History of the Sciences in Tuscany, tome ii. p. 147.

[2] Letter of Galileo, cited by Tiraboschi.

[3] The sentence of the Inquisition on Galileo, one of the most remarkable records of intolerant ignorance and bigoted folly to be found in the history of science, is conceived in the following terms:—"We, the undersigned, by the grace of God, cardinals of the Holy Roman Church, Inquisitors General throughout the whole Christian Republic, Special Deputies of the Holy Apostolical Chair against heretical depravity: Whereas you, Galileo, son of the late Vincenzo Galilei of Florence, aged seventy years, were denounced in 1615 to this holy office, for holding as true a false doctrine taught by many, namely, that the sun is immoveable in the centre of the world, and that the earth moves, and also with a diurnal motion; also, for having pupils whom you instructed in the same opinions; also, for maintaining a correspondence on the same with some German mathematicians; also, for publishing certain letters on the solar spots, in which you developed the same doctrine as true; also, for answering the objections which were continually produced from the holy Scriptures, by glozing the said Scriptures according to your own meaning; and whereas thereupon was produced the copy of a writing, in form of a letter, professedly written by you to a person formerly your pupil, in which, following the hypothesis of Copernicus, you include several propositions contrary to the true sense and authority of the holy Scripture: therefore this holy tribunal, being desirous of providing against the disorder and mischief which was thence proceeding and increasing, to the detriment of the holy faith, by the desire of his holiness, and of the most eminent lords cardinals of this supreme and universal Inquisition, the two propositions of the stability of the sun, and motion of the earth, were *qualified* by the *theological qualifiers* as follows: 1st, *The proposition that the sun is in the centre of the world, and immoveable from its place, is absurd, philosophically false, and formally heretical, because it is expressly contrary to the holy Scripture*; 2dly, *The proposition that the earth is not the centre of the world, nor immoveable, but that it moves, and also with a diurnal motion, is also absurd, philosophically false, and, theologically considered, at least erroneous in faith.* But whereas being pleased at that time to deal mildly with you, it was decreed in the holy congregation, held before his holiness on the 25th day of February 1616, that his eminence the Lord Cardinal Bellarmine should enjoin you to give up altogether the said false doctrine; if you should refuse, that you should be ordered by the commissary of the holy office to relinquish it, not to teach it to others, nor to defend it, nor ever mention it, and in default of acquiescence that you should be imprisoned; and in execution of this decree, on the following day, at the palace, in presence of his eminence the said Lord Cardinal Bellarmine, after you had been mildly admonished by the said lord cardinal, you were commanded by the acting commissary of the holy office, before a notary and witnesses, to relinquish altogether the said false opinion, and in future neither to defend nor teach it in any manner, neither verbally nor in writing; and upon your promising obedience you were dismissed. And in order that so pernicious a doctrine might be altogether rooted out, nor insinuate itself farther to the heavy detriment of the Catholic truth, a decree emanated from the holy congregation of the index prohi-

It is said that, after having pronounced his abjuration, Galileo, as he rose from the kneeling posture, indignant at the monstrous injustice of his age, stamped on the ground, and said in an under tone, *E pur si muove*, It moves notwithstanding. No doubt it does move, and this is the only answer which those who study nature should at all times make to their detractors and persecutors. What signifies the opinion of men when nature herself speaks? Of what value are their prejudices, or even their wisdom, in opposition to her laws? Why denounce as an impiety the observation of the works of God? Such, indeed, are now the sentiments of persons the most enlightened on the subject of theology; the motion of the earth and the immobility of the sun are no longer contrary to the words of Scripture; it is at length admitted that the Holy Spirit spoke to men in the only language which they could comprehend. It is true that this interpretation, which is now universally received, did not appear good in the time of Galileo, since we have seen that he was himself reprehended for having attempted to give it effect; but, from what we have related of the history of his life, it is evident that the persecution exercised against him was the effect, unhappily too common, of the envy which always attaches to great celebrity. There are arms peculiar to every country. Galileo was a heretic in Italy, as Descartes was an atheist in Holland. However, in denouncing to posterity the shameful injustice done to this great man, it must in fairness be admitted that the formidable tribunal by which he was condemned did not exercise towards him its extreme severity. It has been pretended, without any probability, that he was put to the question. But although it is true that, in the inquisitorial style, this seems to be indicated by the words *rigorosum examen* which are found in the text of the judgment, and although, by a singular coincidence, he began about this time to be afflicted with an intestinal hernia, the ordinary consequence of the particular species of torture (*il tormento della corda*) to which he is supposed to have been subjected; yet, for the honour of humanity, these presump-

---

biting the books which treat of this doctrine; and it was declared false, and altogether contrary to the holy and divine Scripture. And whereas a book has since appeared, published at Florence last year, the title of which showed that you were the author, which title is, *The Dialogue of Galileo Galilei, on the two principal systems of the world, the Ptolemaic and Copernican;* and whereas the holy congregation has heard that, in consequence of the printing of the said book, the false opinion of the earth's motion and stability of the sun is daily gaining ground, the said book has been taken into careful consideration, and in it has been detected a glaring violation of the said order, which had been intimated to you; inasmuch as in this book you have defended the said opinion, already and in your presence condemned; although in the said book you labour with many circumlocutions to induce the belief that it is left by you undecided, and in express terms probable; which is equally a very grave error, since an opinion can in no way be probable which has been already declared and finally determined contrary to the divine Scripture. Therefore by our order you have been cited to this holy office, where, on your examination upon oath, you have acknowledged the said book as written and printed by you. You also confessed that you began to write the said book ten or twelve years ago, after the order aforesaid had been given. Also, that you demanded license to publish it, but without signifying to those who granted you this permission that you had been commanded not to hold, defend, or teach the said doctrine in any manner. You also confessed that the style of the said book was, in many places, so composed that the reader might think the arguments adduced on the false side to be so worded as more effectually to entangle the understanding than to be easily solved, alleging in excuse that you have thus run into an error, foreign (as you say) to your intention, from writing in the form of a dialogue, and in consequence of the natural complacency which every one feels with regard to his own subtilties, and in showing himself more skilful than the generality of mankind in contriving, even in favour of false propositions, ingenious and apparently probable arguments. And, upon a convenient time being given to you for making your defence, you produced a certificate in the handwriting of his eminence the Lord Cardinal Bellarmine, procured as you said by yourself, that you might defend yourself against the calumnies of your enemies, who reported that you had abjured your opinions, and had been punished by the holy office; in which certificate it is declared that you had not abjured, nor had been punished, but merely that the declaration made by his holiness, and promulgated by the holy congregation of the index, had been announced to you, which declares that the opinion of the motion of the earth, and stability of the sun, is contrary to the holy Scriptures, and therefore cannot be held or defended. Wherefore, since no mention is there made of two articles of the order, to wit, the order 'not to teach,' and 'in any manner,' you argued that we ought to believe that, in the lapse of fourteen or sixteen years they had escaped your memory, and that this was also the reason why you were silent as to the order, when you sought permission to publish your book, and that this is said by you not to excuse your error, but that it may be attributed to vain-glorious ambition rather than to malice. But this very certificate, produced on your behalf, has greatly aggravated your offence, since it is therein declared that the said opinion is contrary to the holy Scripture, and yet you have dared to treat of it, to defend it, and to argue that it is probable; nor is there any extenuation in the license artfully and cunningly extorted by you, since you did not intimate the command imposed upon you. But whereas it appeared to us that you had not disclosed the whole truth with regard to your intentions, we thought it necessary to proceed to the rigorous examination of you, in which (without any prejudice to what you had confessed, and which is above detailed against you, with regard to your said intention) you answered like a good Catholic. Therefore, having seen and maturely considered the merits of your cause, with your said confessions and excuses, and every thing else which ought to be seen and considered, we have come to the underwritten final sentence against you. Invoking, therefore, the most holy name of our Lord Jesus Christ, and of his most glorious Virgin Mother Mary, by this our final sentence, which, sitting in council and judgment for the tribunal of the reverend masters of sacred theology, and doctors of both laws, our assessors, we put forth in this writing touching the matters and controversies before us, between the magnificent Charles Sincerus, doctor of both laws, fiscal proctor of this holy office of the one part, and you, Galileo Galilei, an examined and confessed criminal from this present writing now in progress as above of the other part, we pronounce, judge, and declare, that you, the said Galileo, by reason of these things which have been detailed in the course of this writing, and which, as above, you have confessed, have rendered yourself vehemently suspected by this holy office of heresy; that is to say, that you believe and hold the false doctrine, and contrary to the holy and divine Scriptures, namely, that the sun is the centre of the world, and that it does not move from east to west, and that the earth does move, and is not the centre of the world; also that an opinion can be held and supported as probable after it has been declared and finally decreed contrary to the holy Scripture, and consequently that you have incurred all the censures and penalties enjoined and promulgated in the sacred canons, and other general and particular constitutions against delinquents of this description. From which it is our pleasure that you be absolved, provided that, first, with a sincere heart and unfeigned faith, in our presence, you abjure, curse, and detest the said errors and heresies, and every other error and heresy contrary to the Catholic and apostolic church of Rome, in the form now shown to you. But, that your grievous and pernicious error and transgression may not go altogether unpunished, and that you may be made more cautious in future, and may be a warning to others to abstain from delinquencies of this sort, we decree that the book of the Dialogues of Galileo Galilei be prohibited by a public edict, and we condemn you to the formal prison of this holy office, for a period determinable at our pleasure; and, by way of salutary penance, we order you, during the next three years, to recite once a week the seven penitential psalms, reserving to ourselves the power of moderating, commuting, or taking off the whole or part of the said punishment and penance. And so we say, pronounce, and by our sentence declare, decree, and reserve, in this and in every other better form and manner, which lawfully we may and can use. So we, the subscribing cardinals, pronounce. Felix, Cardinal di Ascoli; Guido, Cardinal Bentivoglio; Desiderio, Cardinal di Cremona; Antonio, Cardinal S. Onofrio; Berlingero, Cardinal Gessi; Fabricio, Cardinal Verospi; Martino, Cardinal Ginetti." This document is decisive as to the fallacy of the allegation, that "Galileo was not persecuted as a good astronomer, but only as a bad theologian."

tions seem completely destroyed by the conduct which was subsequently observed towards him. It is certain, from the letters of the ambassador of Tuscany, that he was not thrown into the dungeons of the holy office, although the judgment bears so. The prison assigned him was the lodging of one of the superior officers of the tribunal, with permission to walk throughout the whole palace; he was allowed to retain his domestic; and, so far from being put in solitary confinement, he was permitted to receive the visits of his friends as often as he pleased. All this is established by numerous letters of Galileo himself, dated at this period, and which, fortunately for the cause of truth and humanity, have been preserved. If he did not at once recover his entire liberty, his captivity was at least mitigated as much as it could well be, since the prison assigned him was the magnificent palace of the Archbishop of Sienna, Piccolomini, his friend and pupil, surrounded with beautiful gardens, in which he was allowed to take exercise at pleasure. In the beginning of December 1633, the pope granted him permission to reside openly in the country near Florence; and at a somewhat later period, he was allowed to enter the city as often as his infirmities required. Nevertheless, these restrictions prove that he still remained under the surveillance of the Inquisition; and the Italian writers even say that he several times received, from that tribunal, threatening letters, on account of the pursuits to which he still applied himself, and on pretence of the too intimate connection which he maintained with the learned in Germany.

It was no doubt too much thus to afflict an old man who had committed no other error than that of unfolding truths previously unknown. This treatment made a deep impression on his mind, as may be seen from the preface to his two new dialogues on the motion and resistance of solids, which he confided in manuscript to the Count de Noailles, when the latter was on his return to France from Rome, where he had been ambassador. "Confounded and afflicted with the bad success of my other works," says he, "and having resolved to publish nothing more, I have wished at least to place in sure hands some copy of my works; and as the particular affection with which you have honoured me will certainly make you desirous to preserve them, I have chosen to confide these to you." The count lost no time in communicating them to the Elzevirs, by whom they were printed at Leyden, in 1628, 4to; and it may be presumed that this publication did not occasion Galileo as much uneasiness as his disciple Viviani, writing, like himself, near Rome, would lead us to believe; a presumption confirmed by several letters, addressed to his intimate friends, which have fortunately been preserved. In these two dialogues Galileo created a science altogether new, namely, that of the resistance of solids; and he established, with admirable sagacity, the laws, not less novel, of the accelerated motion of heavy bodies, whether falling freely through space or descending on inclined planes. Nor is this the only production of Galileo which the French have had the honour of saving from his enemies. It was a Frenchman, Father Mersenne, who first published his mechanics; a book which, in a few pages, contains, among other discoveries, a demonstration of the laws of equilibrium on the inclined plane, and that other principle so fruitful in consequences, since called the principle of virtual velocities, which consists in this, that, in any machine whatsoever, the power and the weight in equilibrio are inversely proportional to the spaces which they would pass through in a time infinitely small, if the equilibrium were ever so little disturbed.

Oppressed with the weight of years and misfortunes, Galileo still pursued his observations, and worked with indefatigable courage to continue his tables of Jupiter's satellites, when the loss of sight obliged him, at the age of seventy-four, to discontinue his labours. But his faculties survived this deprivation, and he did not cease to meditate on nature though it was now concealed from his view. Surrounded by attentive and respectful pupils, and by the most distinguished persons of Florence, he lived four years in this state of blindness, after which a slow fever terminated his long and brilliant career, on the 9th of January 1642 (the same year in which Newton was born), at the advanced age of seventy-eight. His body was transported to Florence, and buried in the church of Santa Croce; but it was not until near a century later that the splendid monument was erected which now covers his remains and those of his celebrated pupil and friend Viviani.

The most masterly, and at the same time the most impartial estimate which has yet appeared of the services rendered to the cause of human knowledge by the Florentine philosopher, will be found in the Third Dissertation prefixed to this work (see particularly p. 469, 470), to which the reader is accordingly referred; more especially with respect to the preference which Biot, supported by Hume, has been pleased to assign to Galileo over Bacon in pointing out the true method of studying nature, and showing the art, if it may be so called, of interrogating her by means of experiment. On this subject Professor Playfair has left little or nothing to be said by those who come after him. The accomplishments of Galileo as a scholar were scarcely less remarkable than his discoveries in science. His style, which has been happily characterised by Hume, is so elegant and pure that it has become a classical authority; and we have already shown by what happy preparation he attained this excellence in the art of writing. He loved literature, especially poetry, and was so passionate an admirer of Ariosto that he knew the whole of the Orlando by heart. This predilection indeed he carried so far as to suffer it to betray him into injustice towards Tasso; at least if we may judge from an early composition published after his death, but which he most probably never intended to see the light. But if the manner in which he speaks of the *Jerusalem Delivered* be not always consistent with the respect due to so great a poet, something must at the same time be allowed for that freedom with which the mind gives scope to its own impressions when it converses as it were with itself alone, and is not obliged to observe any of those restraints which publication imposes. It is probable that Galileo would have softened his criticism if he had published it; and it may be believed that when his taste was formed, he would have judged it proper to suppress it entirely; for in several passages of his letters he renders justice to the merit of Tasso, although Ariosto always appeared to him superior as a poet. We have entered into this detail, because an interest attaches to all the distinctive characteristics or peculiarities of celebrated men. For the same reason, we shall add, that Galileo was a man of amiable character and agreeable appearance, particularly in his old age; that his temperament was animated, his manners cheerful, and his conversation attractive; and that he preferred living in the country, where his favourite relaxations consisted in the cultivation of his garden, and in the conversation of his friends. He was never married; but he left three natural children, a son, and two daughters, who, after his death, entered a convent, and took the veil.

Without pretending to give an accurate list of all the works of Galileo, we shall content ourselves with the following enumeration of his principal productions:—1. Nuncius Sidereus, Florence, 1610, in 4to, reprinted the same year at Venice in 4to, and at Frankfort in 8vo; 2. Il Saggiatore, nel quale, con bilancia esquisita e giusta, si ponderano le cose contenute, &c. Rome, 1623, in 4to, being a refutation of the Libra Astronomica of the Jesuit Grassini; 3. Dialogi quattro sopra i due massimi Sistemi del

Mondo, Tolemaïco e Copernicano, Florence, 1632, in 4to, translated into Latin by Bernegger, with other pieces, under the title of Systema Cosmicum; 4. Epistolæ Tres de conciliatione Sacræ Scripturæ cum Systemate Telluris mobilis, quarum duæ posteriores nunc primum cura M. Nevræi prodeunt, Lyons, 1649; 5. Considerazioni al Tasso, printed for the first time in 1793, Venice, in 12mo, and Rome, in 4to; 6. Lettere inedite di Uomini Illustri, published by Fabroni, Florence, 1773, in 8vo, in which are included several unedited letters of Galileo. His treatise on Fortification and Military Architecture is preserved in manuscript in the Bibliotheca Riccardiana, of which Lami published a catalogue in 1756. The editions of his collected works, in which is contained much that was never published separately, are, 1. Opere di Galileo Galilei, Bologna, Charles Manolessi, 1656, in 2 vols. 4to, but very incomplete; 2. Opere, &c., Florence, Bothni, 1718, in 3 vols. 4to, scarcely less so; 3. Opere, &c., Padua, 1744, in 4 vols. 4to, being the first edition of the collected works, containing the Dialogue on the System of the World, after the copy corrected and improved by the author; 4. Opere, &c., Milan, 1811, in 11 vols. 8vo, which is the most complete of all. The most extended life which has yet appeared of this illustrious philosopher is that by Louis Brenna, which has been inserted by Fabroni in the first volume of his *Vitæ Italorum*, 1778. Many precious notices are also to be found in Tiraboschi, and in the work of Targioni-Tozetti on the History of the Sciences in Tuscany. (See *Biographie Universelle*, art. Galileo Galilei, by Biot; *Saggio della Filosofia del Galileo*, by Andrès; and Drinkwater's Life of Galileo, in the *Library of Useful Knowledge.*) (A.)

GALIPOLI, a city of Turkey, on the peninsula formerly known as the Adriatic Chersonesus, and the capital of the province of the same name. It is situated on the Dardanelles, at the opening of the Sea of Marmora. It is an open city, and is defended by an old but strong citadel on a height near to it. It contains mosques, Greek churches, and Jews' synagogues, and about 17,000 inhabitants, of whom 10,000 are Turks, 3500 are Greeks, and 3500 are Jews. It has two havens, both spacious and safe, and bazars, which are stored with every description of Asiatic and European merchandise. The inhabitants make the best Morocco leather, and carry on manufactures of cotton and silk, spinning and weaving, and have several establishments for making porcelain ware. It is governed by an aga, who represents the Capudan Pasha, the commander in chief of the province. It is in long. 26. 32. 10. E. Lat. 40. 25. 33. N.

GALL, in the animal economy, the same thing as *bile*. Gall was generally given amongst the Jews to persons suffering death under the execution of the law, to make them less sensible of pain; but gall and myrrh are supposed to have been the same thing, because at our Saviour's crucifixion, St Matthew says that they gave him vinegar to drink mingled with gall; whereas St Mark calls it wine mingled with myrrh. The truth of the matter perhaps is, that they distinguished every thing bitter by the name of gall. The Greeks and Romans also gave such a mixture to persons suffering a death of torture.

GALL, in *Natural History*, denotes any protuberance or tumour produced by the puncture of insects on plants and trees of different kinds. These galls are of various forms and sizes, and not less different in their internal structure than in their external form. Some have only one cavity, and others a number of small cells communicating with one another; and some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy. The former are termed *gall-nuts*, and the latter *berry-galls* or *apple-galls*.

GALL, JOHN JOSEPH, the founder of Phrenology, as it is now called, was descended of a respectable family residing at Tiefenbrunn, two leagues distant from Pforzheim, in Suabia, and born on the 9th of March 1757. His father was a shopkeeper or merchant, and mayor of the village. His parents, who were of the Roman Catholic persuasion, originally intended him for holy orders; but his natural dispositions were adverse to such a destination. He pursued his studies first at Baden, then at Brucksal, and afterwards at Strasburg, where he completed his literary education. Having resolved to study medicine with a view to the practice of physic, he, in 1781, proceeded to Vienna, the medical school of that capital having acquired great celebrity, particularly since the times of Van Swieten and Stoll; and, after passing through the ordinary course, he took his degree.

Being early given to observation, Gall, whilst yet a boy, was struck with the fact, that each of his companions and schoolfellows possessed some peculiarity of talent which distinguished him from the others. One excelled in penmanship, another in arithmetic, a third in the acquisition of languages. The compositions of some were remarkable for elegance, whilst those of others were hard, stiff, formal, and dry; several connected their reasonings in the closest manner, and clothed their arguments in forcible language; many were devoid of the talent for logical arrangement, and incapable of expressing themselves with clearness and precision. Nor were their dispositions less various than their intellectual endowments. Not a few manifested a capacity for employments which they had not been taught, such as cutting figures in wood, or delineating them on paper; some devoted their leisure to drawing or gardening, whilst others abandoned themselves to noisy games, or traversed the woods to gather flowers, search for birds' nests, or catch butterflies. In short, each presented a character peculiar to himself, and Gall did not observe that the individual who, one year, displayed selfish or knavish propensities, became a kind and faithful friend the next. Of his schoolfellows, those with whom he experienced the greatest difficulty in competing, were the boys who committed their lessons to memory with the greatest facility; and such individuals frequently gained from him by their repetitions the places which he had obtained by the merit of his original compositions. Several years afterwards, having changed his place of residence, and still meeting with individuals possessed of the same faculty, he observed that the individuals so gifted had all prominent eyes, and he also recollected that his rivals in the first school had been distinguished by the same peculiarity. On entering the university, he accordingly directed his attention to those students who had large eyes, and, upon inquiry, he found that they all excelled in committing pieces to memory and giving correct recitations, although many of them were by no means remarkable for general talent. As the coincidence thus observed was recognised by the other students in the classes, Gall conceived that it could not be entirely accidental; and hence, from this period, he seems to have come to the conclusion that they stood in an important relation to each other. But if verbal memory was thus indicated by an external sign, it required no great effort of generalization to conceive that the other intellectual powers might have each its appropriate manifestation. Proceeding on this idea or assumption, Gall now directed his attention to individuals distinguished by any remarkable faculty; and, after a course of observation, he conceived himself to have discovered and defined the external characteristics indicative of decided talents for painting, music, and the mechanical arts. Having also become acquainted with several persons remarkable for determination of character, he observed that a particular part of their heads was largely developed, and this development he set down as the external sign or manifestation of the character referred to.

His next step was to look in the head for the indications of the moral sentiments as well as of the intellectual faculties; but here he experienced considerable difficulties. Hitherto he had been ignorant of the opinions of physiologists concerning the brain, and of metaphysicians respecting the mental faculties; and, on turning to books, he became so much perplexed by the discordance of the views therein inculcated, that, for a time, he hesitated as to the correctness of his own observations. He found that, whilst Pythagoras, Plato, Galen, Haller, and others, placed the sentient soul in the brain, Aristotle fixed its residence in the heart, Van Helmont in the stomach, Descartes in the pineal gland, and Drelincourt in the cerebellum; that, according to many philosophers and physiologists, all men are born with equal mental faculties; and that the differences observable amongst mankind are not ascribable to any original or constitutional inequality of powers, but the result partly of education, and partly of the diversified circumstances in which individuals are placed. But if all differences are accidental, it is evident that there can be no natural signs of predominating faculties, and, consequently, that the project of attempting, by observation, to discover the functions of the different portions of the brain, must be abandoned as hopeless. Sensible of this, Gall combated the difficulty by denying the truth of the doctrine of original equality on which it is founded. He contended that persons who have all received the same or very nearly the same education unfold each a distinct character, over which circumstances appear to exercise only a limited control; that individuals, whose education has been conducted with the greatest care, and on whom the labours of instructors have been most freely lavished, frequently remain far behind their companions in attainments; that many, even with the most ardent desire, followed out by the most persevering efforts, cannot, in some pursuits, attain even to mediocrity; that, in point of fact, instructors of youth do not appear to attach much faith to the system which teaches the equality of mental faculties, and think themselves entitled to exact more from one scholar and less from another; that the doctrine of Scripture, according to which, each will be required to render an account only in proportion to the gifts which he has received, serves to confirm this view, and is, moreover, in accordance with observation and experience. On these grounds, Dr Gall concluded that there is a natural and constitutional diversity of talents and dispositions amongst men; and that, supposing the exercise of the mental faculties dependent on the functions of the brain, the external signs of these faculties may be determined by observation.

Abandoning every theory and preconceived opinion, therefore, he applied himself to the discovery of those signs of the existence of which he had thus satisfied his own mind. Being physician to a lunatic asylum at Vienna, he had opportunities of making observations on the insane; he visited prisons, and resorted to the seats of learning; he was introduced to the courts of princes and the tribunals of justice; wherever he heard of an individual remarkable either for his mental endowments or defects, he studied the development of his head; and at length he conceived himself warranted in maintaining that particular mental powers are indicated by particular configurations of the shell or case in which the brain is lodged. Hitherto he had resorted only to physiognomical indications in order to discover the functions of the brain; but, being convinced that physiology is imperfect when separated from anatomy, he felt the necessity of instituting anatomical researches into the structure of the brain.[1] Accordingly, in every instance where an individual whose head he had examined whilst alive happened to die, he used every means to obtain permission to examine the brain, and frequently did so; and he states it as a general fact, that, on the skull being removed, the brain, covered by the dura mater, presented a form corresponding to that which the skull had exhibited in life. Thus, by successive steps, by first observing a concomitance between particular talents and dispositions, and particular forms of the head, and next by ascertaining that the figure and size of the brain were indicated by these external forms, Dr Gall conceived that he had determined the intellectual dispositions corresponding to about twenty organs, or, in other words, ascertained the residences of as many intellectual faculties of the first order; and these organs he named according to the faculty or propensity which he attributed to each respectively. In short, he maintained that the intellectual dispositions being innate, have their seats in the brain, where the organs of the faculties are also situated; that the more prominent any isolated point on the skull is, the greater is the activity of the faculty, the organ of which is there placed; and that the part of the brain where such faculty resides and acts, by pressing on the skull, forms, on its convex surface, a protuberance, which indicates externally the organ, and is, in fact, its invariable sign.

Dr Gall first became known as an author by the publication of two chapters of a work entitled *Philosophisch-Meicinishe Untersuchungen über Natur und Kunst im gesunden und krauken Zustande des Menschen*, Vienna, 1791. This work was not continued; but in the two chapters published, Dr Gall evinced the spirit which subsequently guided his researches into the intellectual and moral nature of man. The first written notice of his inquiries respecting the differences of form observable in the human head was contained in a familiar letter addressed to Baron Retzen, which appeared in the *Deutschen Mercur* of December 1798; but two years before this Dr Gall had commenced giving courses of private lectures at Vienna, where his doctrines soon attracted general attention; and Froriep, Martens, and Walther, were among his hearers. He continued his lectures for five years, with increasing success, when, at length, upon the 8th of January 1802, the Austrian government issued an order, interdicting them, on the ground that the doctrines therein promulgated were dangerous to religion; and, in a general regulation which accompanied the order, all private lectures were prohibited, unless specially permitted by the public authorities. Dr Gall understood the object of this regulation, and never solicited permission; but, as usually happens, the prohibition stimulated curiosity, and the doctrines thus interdicted were studied with greater zeal than before. It is difficult to perceive what object the Austrian government proposed to attain by this foolish interposition, more especially as publications on the subject continued to be permitted, provided they abstained from reflecting on the government for issuing the order above mentioned. On the 6th March 1805, Dr Gall left Vienna, in company with Dr Spurzheim, whom he had now associated with him in his pursuits, and proceeded to Berlin, where he remained a short time; he then visited all the principal towns and universities of Germany, and in November 1807 repaired to Paris, where he established himself as a medical practitioner, and remained till the time of his death. To the charge of Spinozism or atheism, which was strongly urged against him, particularly by some of the French scholars, Dr Gall replied in a work entitled *Des Dispositions innées de l'Ame et de l'Esprit, ou du Matérialisme*, Paris, 1812, in 8vo, which he seems to have intended as an authoritative exposition of the metaphysics of the new science. But a much ruder onset awaited it. In 1815, and again in 1826, craniology was attacked in able articles inserted in the *Edinburgh Review*, where the united powers of argument and ridicule were forcibly directed against it by writers possessing an equal mastery over both; but the results of Dr Gall's observations were not, in the opinion of his followers, destroyed, nor even materially affected, by the critical severity with which these had been examined in the Review; and their confidence in the truth of the system, which to the uninitiated appeared to be overthrown, gained strength from each successive shock to which it was exposed. But whatever may be thought of Dr Gall's discoveries, either in reference to the philosophy of mind, or to the moral and religious opinions of mankind, it seems to be pretty generally conceded, that, by his dissections and observations, he has considerably advanced the knowledge of the cerebral system, and that, even if he be accounted a bad philosopher, he has at least shown himself an able anatomist. He demonstrated, what before was only conjectured, that cerebral matter does not derive its origin from the brain, but from the spinal marrow; which, expanding as it proceeds, at length forms the two hemispheres into which the brain is divided. In conjunction with Spurzheim, Dr Gall published at Paris, in 1810, *Anatomie et Physiologie du Système nerveux en général, et du Cerveau en particulier;* but of this work there only appeared a volume and a half. The most elaborate of his productions, however, is *Organologie, ou Expositions des Instincts Penchans, &c. et du siège de leurs Organes*, which was completed in 1825. His *Histoire des Fonctions du Cerveau* had appeared in 1822, in two vols. 8vo. In 1828 Dr Gall died at Paris, where he had for many years practised medicine with success, leaving his mantle to Dr Spurzheim, who had been long associated with him both in the pursuit and the propagandism of phrenology. (See *Biographie des Hommes Vivants*, art. Gall; and *Transactions of the Phrenological Society*, Edinburgh, 1824; *Nécrologie*, 1828; *Edinburgh Review*, vols. xxv. and xlv.) (A.)

---

[1] Having observed a woman, aged fifty-four years, who from her youth had been afflicted with water in the head, yet possessed a mind as active and intelligent as that of any other individual of her class, Dr Gall declared his conviction that the structure of the brain must be different from what it was generally supposed to be; a conclusion which Tulpius had already drawn from observing a hydrocephalic patient, whose mental faculties remained unaffected by the disease under which he was labouring. This, and other analogous cases, convinced Dr Gall of the necessity of instituting minute anatomical researches into the structure and functions of the brain.

GALL, *St*, a canton of Switzerland. It is bounded on the north by the canton of Thurgau, on the north-east by the Lake of Constance, on the east by the Austrian dominions and the principality of Lichtenstein, on the south-east by the Grey Bunden, on the south-west by Uri, and on the west by Schwitz and Zurich. It is 870 square miles in extent, and contains 45,342 houses, with 146,700 inhabitants, about equally Catholics and Protestants. It is divided into eight *amtsbezirke* or bailiwicks. The greater portion of the land is mountainous; but the districts of Rhinethal, Norschach, and Gossau, have some fine plains intermixed with gentle hills. In the other divisions the mountains are rather lofty, varying in height from 4300 to 7500 feet. None of the mountain regions of Switzerland have been less explored, or are less known, than those of this canton. From them issue many of those rivers which increase the volume and the rapidity of the Rhine before it enters into the Lake of Constance.

Although the cultivation on the plains is good, the canton does not produce sufficient corn for the consumption of the inhabitants; but potatoes are extensively planted, and fruits of all kinds are raised in large quantities and of excellent sorts, especially apples, which furnish cider as the common drink. The milk of the cows is more used for butter than for cheese. Some wine is made; but for want of care it will not bear to be long kept.

The manufactures of the canton are prosperous and increasing. The muslins, printed calicoes, and cotton goods, find ready sale at the German fairs. There are many large mills for spinning cotton and linen. The chief trade is in the capital, at Utznach, and Sargans. The government is republican, residing in two assemblies chosen by those who possess property to a stipulated amount, whilst the members to be chosen must have a prescribed amount of capital. The canton contributes to the general fund of the confederacy 39,450 francs yearly, and furnishes for the general defence a contingent of 2630 men; but all the population capable of bearing arms are regimented, and taught the use of them.

GALL, *St*, the capital of the canton of that name in Switzerland. It stands between two hills, on the river Steinach. It is surrounded with walls and ditches, but is well built, with broad streets and good houses. It contains 960 houses, and about 9500 inhabitants, of whom 8000 are Protestants. It is a flourishing city, of great industry in manufactures of cotton, linen, and silk, and some in woollen goods. Long. 9. 21. 37. E. Lat. 47. 21. 50. N.

GALLA, an Abyssinian nation. See ABYSSINIA.

GALLAND, ANTONY, a celebrated orientalist and numismatist, was born, in 1646, at Rollat, near Montdidier, in Picardy. His life shows what may be effected by the love of study, firm resolution, and irreproachable morals. By a rare perseverance in his pursuits, Galland triumphed over the caprices of fortune; by the rectitude and nobleness of his character he was enabled to overcome all the disadvantages of his humble lot. Born of poor parents, he lost his father at the age of four, being the youngest of seven children. But his mother, though reduced to live by the labour of her hands, contrived to place him in the college of Noyon, where the principal and a canon of the cathedral charitably undertook the care and expense of educating young Galland. At the age of fourteen he lost both his benefactors at the same time, and returned to his mother with no other wealth than the knowledge of a little Latin, Greek, and Hebrew, a decided taste for letters, and a firm resolution to apply himself to learning. But as his mother could not of course furnish the means necessary for the completion of his studies, it became necessary to learn a trade and renounce literature. This cruel distraction Galland supported for a year, when, finding it intolerable, he one day set out for Paris, with no other resource than the address of an old relation who was in good circumstances, and that of an ecclesiastic whom he had sometimes seen at the house of the canon of Noyon. The hardihood of this resolution created an interest in his favour; the sub-principal of the college of Plessis made him continue his studies at that seminary, and then confided him to the care of M. Petitpied, doctor of the Sorbonne. Anything more fortunate could not have happened to Galland than this last act of kindness, which may be said to have prepared, and indeed ensured the success of his literary career. He now extended his knowledge of Hebrew and the other oriental languages, attended the courses of instruction in the Royal College, and even undertook to make a catalogue of the oriental manuscripts of the Sorbonne. Doctor Petitpied had just placed him in the house of M. Godouin, professor in Mazarin College, when M. de Nointel set out, in 1670, on his embassy to Constantinople, and took along with him young Galland, whose labours and acquirements had already attracted notice. The intention of this minister was to employ Galland in procuring from the Greek churches formal attestations of the articles of their faith, which then formed the subject of a grand controversy between Arnauld and Claude. Galland soon acquired at Constantinople a knowledge of the vulgar Greek, from his long conferences with the Greek prelates, and obtained from them attestations, along with much information on the subjects discussed in France. De La Croix, secretary of the embassy, makes no mention of these researches in his *Mémoires;* but it may be supposed that he found them useful in the composition of *Etat présent de l'Eglise Grecque et Maronite*, published in 1695, 12mo, and reprinted without any alteration under the title of *Turquie Chrétienne.* Galland accompanied M. de Nointel in his journey to Jerusalem, and availed himself of the opportunity to copy a great number of inscriptions, and even to remove them, as often as he found it practicable to do so. Of these, Montfaucon has published some fragments in his *Palæographie.* From Syria Galland returned directly to France, whence he immediately set out again for the Levant with the intention of collecting more medals. In 1679 he undertook a third voyage, being charged by the India company to collect every thing calculated to enrich the cabinet of Colbert; but this commission having ceased in consequence of changes which took place in the company, Colbert, and, after his death, Louvois, instructed Galland to continue his researches, and caused the title of antiquary to the king to be conferred on him. At the moment when he was about to embark at Smyrna to return to his native country, he was on the point of perishing in an earthquake. The house which he occupied fell, and buried him in the ruins, under which he remained until next day, breathing with difficulty through accidental openings in the rubbish. On his return to Paris, Thevenot, keeper of the king's library, and D'Herbelot, the celebrated oriental scholar, availed themselves of his labours. But death having soon deprived him of both these learned men, he attached himself to Bignon, a zealous protector of men of letters, whom he also lost the following year. It appears to have been the fortune of Galland continually to lose those useful protections which acknowledged merit is sometimes long in obtaining; but such was the esteem inspired by his attainments and his character, that death no sooner deprived him of one support than he found another. Foucault, intendant of Lower Normandy, supplied the place of Bignon, and received Galland into his house, where, in the midst of a fine library, and a numerous collection of medals, he applied himself to the composition of different works, in which he turned to account his knowledge of the Arabic, Persian, and Turkish languages, with which he had rendered himself familiar during his residence in the East. In 1701, he was admitted into the Academy of Inscriptions, although he resided at Caen; in 1706 he returned to take up his habitation in Paris; and, three years afterwards, he obtained the chair of Arabic in the Royal College of France. This learned man terminated his laborious, useful, and irreproachable life, on the 17th of February 1715, at the age of sixty-nine. The following is a list of his printed works: 1. Trois Lettres touchant la critique M. de Guillet, sur le Voyage de Grèce de Spon, printed in the reply of Spon, Lyons, 1679, in 12mo; 2. Paroles remarquables, bons mots, et maximes des Orientaux, traduits de leurs ouvrages Arabes, Persans, et Turcs, avec des remarques, Paris, 1694, in 12mo; 3. Lettres touchant l'Histoire des quatre Gordiens, prouvée par les Médailles, Paris, 1696, in 12mo; 4. Lettre touchant quatre médailles antiques, publiées par le P. Chamillard, Caen, 1697, in 12mo; 5. Lettre touchant la nouvelle explication d'une médaille d'or du cabinet du Roi, Caen, 1698, in 12mo; 6. Lettre sur le même sujet, printed in the Journal des Savants, 15th August 1705: 7. Observations sur quelques médailles de Tétricus le père, et d'autres tirées du cabinet de M. Ballonseaux, Caen, 1701, in 8vo; 8. De l'origine et du progrès du Caffé, translated from an Arabic manuscript in the library of the king, Caen, 1699, in 12mo; 9. Les Mille et Une Nuits, contes Arabes, traduits en Français, Paris, in 12 vols. 12mo; 10. Relation de la Mort du Sultan Osman, et du couronnement du Sultan Mustapha, translated from the Turkish, Paris, 1678, in 12mo; 11. Several articles in the Journal de Trévoux; 12. Letters written from Smyrna and Constantinople; 13. Contributions to the Menagiana, as well as to the Bibliothèque Orientale of D'Herbelot, who died before the printing of the work was completed; 14. Ten dissertations and memoirs for the collection of the academy of which he was a member. Since the death of Galland there have been published of his, 1. Contes et Fables Indiènnes de Pidpaï et de Lokman, Paris, 1724, in 12mo; 2. Dissertation sur une médaille Grecque de l'Empereur Diaduménien, frappée à Ephèse, 1739; 3. Relation de l'esclavage d'un Marchand Français de la ville de Cassis à Tunis, 1809. The manuscripts left by Galland were, 1. Histoire des Princes de la lignée de Tamerlan, depuis le Sultan Abou-Saïd-Bahadur, jusqu'au Sultan Abou-Saïd-Kourkan; 2. Histoire Othomane, traduite du Turc de Naïma Effendi; 3. Vocabularium Turcico-Latinum; 4. A translation of the History of Djenguyz-Khan, extracted from the Persian History of Mirkhoud; 5. Catalogue d'écrivains Arabes, Persans, et Turcs; 6. Journal de mon séjour à Constantinople pendant l'année 1672 et 1673; 7. Dictionnaire Numismatique; 8. Relation de ses Voyages; 9. Traduction de l'Alcoran; 10. Nécrologie de la mort des Savants pour chaque jour de l'année de 1500 à 1701; 11. Relation d'un Voyage fait à Constantinople en 1679 et 1680; 12. Etat présent des îles de Samos, de Nicaire, de Patmos, et du Mont Athos; 13. Description de la Ville de Constantinople en 1671 et 1672; 14. Relation des Evénemens qui se sont passés à Constantinople en 1671 et 1672. (A.)

GALLEON, in naval affairs, a sort of ship or vessel employed by the Spaniards in the commerce of the West Indies.

GALLEOT, a small galley designed only for chase, and carrying one mast, with two pattereroes.

GALLERY, in *Architecture*, a covered place in a house, of much greater length than breadth, and usually in the wings of a building, its use being chiefly to walk in.

Gallery, in *Fortification*, a covered walk across the ditch of a town, made of strong beams covered with planks, and loaded with earth. Sometimes it is covered with raw hides, to defend it from the fire of the besieged.

Gallery of a Mine is a narrow passage or branch of a mine carried on under ground to a chamber in a work designed to be blown up.

GALLEY, a kind of low flat-built vessel, furnished with one deck, and navigated with sails and oars, particularly in the Mediterranean. By the Greek authors under the eastern empire this kind of vessel was called *γαλαια* and *γαλεια*, by the Latin authors of the same time *galea;* and hence, according to some, the modern denomination. Some say it was called *galea*, because a casque or helmet was carried on the prow, as Ovid attests (*de Tristibus*). The French call it *galère*, because it seems the top of the mast is usually cut in the form of a hat, which the Italians call *galero*. Others derive both *galea* and *galère* from a fish called by the Greeks *γαλεωτης* or *ξιφιας*, and by us the *sword-fish*, which this vessel resembles. Others, again, derive *galley*, *gallea*, *galère*, *galleasse*, &c. from the Syriac and Chaldee *gaul*, and *galin*, a man exposed on the water in a vessel of wood.

GALLI, in *Antiquity*, a name given to the priests of Cybele, from the river Gallus in Phrygia; but of the etymology of the name we have no certain account.

GALLICIA, a division of the Austrian empire, usually designated as a kingdom. The whole of it formerly constituted a part of the kingdom or republic of Poland, and, by the successive dismemberments of that unfortunate country, has been transferred to the house of Austria. It is a long tract of land, one part being the most northern territory of the empire, whilst another part enters into the middle region of it. It extends between 47. 10. and 50. 44. of north latitude, and between 18 47. and 26. 25. east longitude, over 33,572 square miles. It is bounded on the north by the republic of Cracow and the kingdom of Poland, on the east by Russia, on the south-east by Turkish Moldavia, on the south and south-west by Hungary, and on the west by the circle of Teschen, in Moravia.

According to the census of 1817, Gallicia contained ninety-eight cities, 191 market-towns, 6175 villages, and 617,210 dwelling-houses. The inhabitants then amounted to 3,761,922, of whom 182,650 were Jews. Since that period the population has rapidly increased, and in 1830 it was calculated at 4,500,000. The prevailing religion is the Catholic, but divided into the Latin and the Greek ritual. There are a bishop and thirty-six churches of the Greek church, nineteen congregations of Lutherans, and thirteen of Calvinists, while the Jews have 294 synagogues, which are governed by a rabbi and six elders. All are alike established and paid by the government.

The land stretches out gradually from the north side of the Carpathian Mountains, and terminates in that vast plain which extends to the Baltic Sea, with scarcely an intervening hill. The Carpathians form part of Gallicia, extending in some of their projections to the banks of the Vistula. The more eastern circles are very mountainous, and those of Bukovina and Czernowitz peculiarly so. The declination of the land is generally towards the north, and the streams, which all fall into the Vistula, are emptied into the Baltic Sea, excepting a small portion of the eastern part, the waters of which run to the Black Sea, after joining the Danube. The Vistula is not a river of Gallicia, but merely forms part of the boundary between it and the kingdom of Poland. It receives the waters of the following rivers: 1*st*, those of the Dunajew, which rises in the Carpathians, receives the waters of the Poprad, also a navigable river, and some smaller streams, and after a course of 115 miles through the circles of Sandec, Bochnia, and Tarnow, falls into the Vistula near Nowopole; 2*d*, those of the Wisloka, which rises in the Carpathians, and after a course of eighty miles through the circles of Jaslow and Tarnow, enters the Vistula; 3*d*, those of the San, which receives the tributary streams of the Wislok and Tanew, and, after a tortuous course of nearly 200 miles, is lost in the Vistula near Lapiszow; 4*th*, those of the Bug, which rises near Soligory, in the circle of Zloczow, and above Sokal enters the kingdom of Poland. The rivers which run to the Black Sea are but small till they quit Gallicia, though their sources are within the province. They are, the Dniester, the Stry, the Podhorze, the Pruth, the Sereth, and the Moldawa. There are no canals, and no lakes of any extent.

From the nature and extent of the country, the soil is very various. In the west and in the north there are many sandy tracts, in the vicinity of the rivers many morasses, and, taken as a whole, only indifferent land; but in the east and south-east divisions the soil is for the most part excellent and easily worked, and with moderate agriculture is found highly productive.

That part of the land which is most naturally fertile is so badly cultivated as to yield but little increase. Wheat and rye are said not to produce more than five times the measure of the seed that is sown, and barley and oats not more than six times. The poverty and the ignorance of the peasantry are impediments to their gaining much more produce than they consume; and for what little surplus corn they gain, it is generally sold to the usurious Jews before it is thrashed out. The working cattle and utensils are of the most miserable kind; and very little manure is applied to renovate the exhausted soil. About one third of the land is covered with forests, and some fine timber is annually supplied to commerce. The chief production is corn, some small portion of which is sent by the Vistula to Dantzick, but the larger part is sold to the inhabitants of the eastern parts of Hungary. Oxen, horses, and cows, are few, and of bad races, though the Austrian government have taken much pains to introduce better breeds.

The chief mineral production is rock-salt, from the great mine near Cracow, which supplies a considerable part of Gallicia, Bohemia, and Austrian Silesia. The mine in question, Wieliczka, yields annually near 25,000 tons of culinary salt. There are also some mines of iron, and others of zinc, but they are not very productive.

There is scarcely any commerce except for the native productions, but the contraband trade is very extensive, being conducted by the Jews from Lemberg and Brody, over the boundaries of the Russian empire, and with Cracow for colonial wines. The manufactures are almost exclusively of a domestic kind.

GALLICISM, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages. With us it is used to denote such phrases or modes of speech in English as are formed after the French idiom.

GALLIPOLI, a sea-port, the seat of a bishop, in the province of Otranto, in the kingdom of Naples. It is situated on an island in the Bay of Taranto, but connected by a bridge with the main land. The haven is connected by a mole, but the entrance is dangerous on account of the rocks. It is strongly fortified both on the land and the sea side. It contains, besides the cathedral, ten churches, an ecclesiastical seminary, with some other establishments for education, and, with the suburbs, 8141 inhabitants. The land near it yields oil of great celebrity. In the city, cotton, hosiery, and muslins, are manufactured, and an extensive tunny fishery is carried on. Long. 17. 2. E. Lat. 40. 20. N.

GALLOIS, JOHN, one of the founders of the *Journal des Savans*, was born at Paris on the 11th of June 1632. From his infancy he evinced a strong inclination for learning, which his father, an advocate in the parliament, cultivated with the greatest care. Having embraced the ecclesiastical state, he turned his studies towards theology, and at the same time endeavoured to perfect himself in the knowledge of Greek and of Hebrew, that he might be able to read the sacred books in the originals; he also devoted his leisure hours to literature and the sciences; and as he was endowed with an excellent memory, as well as a sound judgment, his different acquisitions arranged themselves without confusion or disorder in his mind. To learning equally solid and various he joined the talent, then rare among scholars, of writing his mother tongue with precision and elegance; and hence no one could be better qualified than he for conducting a work having for its object to make known the literary and scientific productions of other nations. Such was the object of the *Journal des Savans*; and as the privilege had been withdrawn from Sallo, on the complaints of some writers whom he had censured with too great bitterness, Colbert bestowed it on the Abbé Gallois in 1666. The latter had the sole charge of this journal till 1674, when the amount of labour which it imposed, and his other avocations, forced him to abandon it altogether. Colbert, who had appreciated the merit of Gallois, gave him at first an apartment in his hôtel, and afterwards, during his journeys to Versailles, intrusted it entirely to his care. It has been alleged that this great minister desired to learn Latin, and that he retained the Abbé Gallois for the purpose of instructing him in that language. But, however this may be, it is certain that, while Colbert lived, Gallois enjoyed the highest favour, although he never took advantage of it to promote his own advancement or fortune. On the contrary, he was singularly moderate and disinterested; the only benefice he possessed was the abbey of Corres, the revenue of which was so small that he resigned it because it had become chargeable to him, and never thought of asking another. But if he was careless of all that concerned himself, none was more active or more indefatigable in soliciting assistance for unfortunate men of letters. It is believed that it was he who gave to the minister the plan of the Academy of Inscriptions, although he did not become a member; but he had been admitted into the Academy of Sciences in 1668, and in 1673 he filled the place of Bourzéis in the French Academy, being admitted the same day with Fléchier and Racine. After the death of his illustrious protector, he obtained the place of keeper of the king's library; and, some years afterwards, when he lost this situation, he was, by way of compensation, appointed professor of the Greek language in the Royal College. After the remodelling of the Academy of Sciences, he was placed in the class of geometry; and he then proposed to publish the treatise of Pappus, of which there only existed a defective Latin translation; but this design was not carried into execution. The Abbé Gallois died on the 19th of April 1707, in the fifty-seventh year of his age. Notwithstanding the extreme mediocrity of his fortune, he had collected more than twelve thousand choice volumes, a catalogue of which was printed in 1710. Besides his contributions to the *Journal des Savans*, the Abbé Gallois wrote, 1. Traduction Latine du Traité de Paix des Pyrenées, Paris, 1659, in fol.; 2. Remarques sur le projèt de l'Histoire de France, dressé par Ducange, printed in the new edition of the *Bibliothèque Historique de France*, tome iii.; 3. Réponse à l'écrit de David Gregory, touchant les lignes appelées Robervalliennes, qui servent á transformer les figures, Mém. de l'Acad. des Sciences, 1692; with some others of less note. The éloge of Gallois was pronounced by Fontenelle. (A.)

GALLON, a measure of capacity both for things dry and liquid, containing four quarts.

GALLOP, in the manège, is the swiftest natural pace of a horse, performed by reaches or leaps; the two forefeet being raised almost at the same time, and when these are in the air, and just ready to touch the ground again, the two hind feet are lifted almost at once. The word is borrowed from the barbarous Latin *calupare*, or *calpare*, to run. Some, however, derive it from *caballicare*; and others from the Greek *καλπαζειν, to spur a horse.*

GALLOWAY, a province of Scotland, divided into two districts, comprehending the stewartry of Kirkcudbright and Wigtonshire. See KIRKCUDBRIGHT and WIGTONSHIRE.

GALLOWS, an instrument of punishment, on which persons convicted of capital crimes are executed by hanging. Amongst our ancestors it was called *furca*, or fork; the gallows being a fork driven into the ground, across the legs of which was laid a beam, to which the rope was fastened.

GALLUS, C. CORNELIUS, a native of Forum Julii, now *Frejus*, in Gaul, was distinguished amongst Latin poets for his elegiac poetry, being the intimate friend of Virgil, who speaks in the very highest terms of his works. He was appointed prefect of Egypt by Augustus 30 B. C., and was governor at the time when Antony and Cleopatra put an end to their lives. A short time afterwards he was recalled, and being accused of treason, was tried and condemned to death (26 B. C.); but he escaped the ignominy of a public execution by suicide, at the age of forty, according to Eusebius. Of his four books of elegies, which he addressed to his beloved Lycoris, nothing has been preserved. The six elegies known under his name are the work on Maximianus Gallus Etruscus, who flourished under Anastasius (491, A. D.). Besides these elegies, Gallus translated a Greek poem of Euphorion of Chalcedon; and some ascribe also to him the poem Ciris, generally considered as the work of Virgil. (Fabric. *Bibl. Lat.* i. 14; Souchay, in the *Mém. de l'Acad. des Inscript.* tom. xvi. p. 399.)

GALVANI, LOUIS, a celebrated natural philosopher, was born in 1737, at Bologna in Italy, where many of his relations had arrived at distinguished eminence in jurisprudence and divinity. From boyhood he became enamoured of the austerities of the Catholic religion, and attached himself to a convent, the monks of which were celebrated for their attention to the solemn duty of visiting the dying. He wished much to become a member of this order, but was prevailed on by one of the brotherhood to relinquish the idea, and then turned his attention to the study of medicine in its various branches. He studied under Beccaria, Tacconi, Galli, and especially Galleazzi, whose daughter he afterwards married. In 1762 he acquired great reputation by his inaugural thesis *De Ossibus*, and was soon afterwards chosen as public lecturer in the university of Bologna, and reader in anatomy to the institute of that city. His talent for lecturing was so much admired that vast numbers constantly attended him; and he employed his few leisure hours in making experiments and in the useful study of comparative anatomy. We find in the Memoirs of the Institute of Bologna a number of curious observations by Galvani on the urinary organs, and also on the organs of hearing in birds.

Soon after his reputation for anatomical and physiological knowledge had been fully established in the Italian schools, a mere accident led him to that interesting discovery which will transmit his name to the latest posterity. His wife, for whom he cherished the most ardent affection, and with whom he had been united for a number of years, being in a declining state of health, was using a soup made of frogs by way of restorative. Some of these animals, skinned for the purpose, happened to be lying on a table in Galvani's laboratory, where also stood an electrical machine, when one of the persons who assisted him in conducting his experiments unintentionally brought the point of a scapel near the crural nerves of a frog which lay near the conductor, and immediately the muscles of the limb were violently convulsed. Signora Galvani, a woman of a penetrating understanding, and a lover of science, having witnessed the phenomenon, instantly informed her husband. On his arrival Galvani repeated the experiment, and discovered that the convulsions only happened when the scapel was in contact with the nerve, and when a spark was at the same time drawn from the conductor. After an almost endless variety of experiments, conducted with great ingenuity, but which it would be foreign to the design of this article to enumerate here, he concluded that all animals have within them an electricity of a peculiar nature; that this fluid is contained in other parts, but is most apparent in the nerves and muscles; and that it is secreted by the brain, and diffused by the nerves through various parts of the body. To this new principle, which is now commonly called *Galvanism*, he gave the name of *Animal Electricity*.

He compared each muscular fibre to a small Leyden phial, and attempted to explain the phenomena of muscular motion by analogies taken from that instrument. He also thought of its pathological influence in rheumatic, convulsive, paralytic, and other nervous affections. His first publication on this grand discovery was entitled *Aloysii Galvani de viribus Electricitatis in Motu Musculari Commentarius*, which made its appearance in 4to in the year 1791, and was printed for the Institute of Bologna. This work instantly attracted the attention of philosophers both

Galvani.

in Italy and other countries; and it was soon followed by numerous publications, in some of which the sentiments of Galvani were defended, and in others opposed. The celebrated Volta turned his attention to the subject, and produced a number of arguments to prove that Galvani's opinion respecting animal electricity was erroneous, deriving the phenomena from the electric matter of the atmosphere, and allowing the nerves and muscles no higher function than that of being the most sensible tests hitherto discovered. The doctrine of Volta met with many admirers and advocates; yet there are still to be met with in the learned world many persons who support the opinions of Galvani, and adhere to his original theory, in the defence of which he displayed equal candour and ingenuity, and by which he may be justly considered as deserving that distinguished place amongst experimental philosophers, which the union of his name with the most interesting natural phenomena will probably for ever secure to him.

These important inquiries, joined to the duties of his office as professor, and his extensive practice as surgeon and accoucheur, in both of which capacities he eminently excelled, afforded abundant scope for his indefatigable industry. He composed a variety of memoirs upon topics connected with his profession; but these have not, as far as we know, been published. He delighted to converse with men of science, and to read and investigate the merits of new publications in their society, which he found a valuable source of intellectual improvement.

The character of Galvani in private life is allowed to have been most exemplary; and his sensibility, which was naturally strong, received a violent shock in the death of his wife, Lucia Galleazzi, in 1790. This event brought on an alarming melancholy, which he delighted to encourage, by visiting her tomb in the nunnery of St Catharine, and pouring out his unavailing lamentations over her grave. He was punctual in the discharge of his religious duties, and retained through life the pious impressions which had been early made on his mind. To this may probably be traced the misfortune which afterwards befel him, and which undoubtedly hastened his end. The Cisalpine republic having required of all those holding public employments an oath to the government, Galvani refused to take it. Who can blame him, says M. Alibert, for having followed the voice of his conscience, that internal and sacred voice which alone prescribes the duties of men, and which preceded all human laws? Who can avoid commending him for having sacrificed, with exemplary resignation, all the emoluments attached to the office which he held? Besides, this learned professor entertained strict notions as to those solemn obligations, which are so often abused in the hope of strengthening the laws of empires; he thought, with reason, that they were only suitable to nations incapable of violating them. Deprived of his rank and employment, and almost reduced to indigence, Galvani retired to the residence of his brother James, and soon afterwards fell into a state of extenuation and languor, which, notwithstanding all the skill and attention, equally enlightened and generous, of Doctors Uttini and Cingari, continued to gain ground. Moved by his great celebrity, and ashamed of the severity with which they had treated a man who valued his conscience above all earthly possessions or distinctions, the Cisalpine government now decreed that, notwithstanding his obstinacy, he should be reinstated in his chair. But the indulgence was useless; it came too late. His sensibility had received too many violent shocks to leave a hope of recovery; and death, which he had for some time desired, at length came to his relief on the 4th December 1798. In the Memoirs of the Institute of Sciences of Bologna are to be found the works, few in number, but of the highest importance, which have immortalized the name of Galvani. These are, 1. De renibus atque ureteribus volatilium; 2. De volatilium aure; 3. De viribus Electricitatis in motu musculari Commentarius, already mentioned.

GALVANISM is the name which has been given to that branch of physical science which treats of the chemical agencies of electricity, and of its influence upon the animal frame. The chemical effects of electrical action had been previously studied by Cavendish as a branch of ordinary electricity, and it was not till the year 1790, when Galvani made the interesting discovery that muscular contractions were excited in dead frogs by the contact of metals, that the new science of Galvanism was established. The boundaries of Galvanism were widely extended by the invention of the pile in 1800, by M. Volta of Corna, in consequence of which the name of Voltaic Electricity has been very generally substituted instead of Galvanism.

Had we been disposed to adopt the earlier and more popular name, and to have treated the subject under the foresaid head, the state of the science would have forced us to abandon our design. The splendid discoveries of Mr Faraday, to which we have referred in various parts of our article on electricity, have given a new form to electrical science; and as but a part of them have been published, we could only have presented our readers with an imperfect and disjointed article, the defects of which it would have been necessary to supply in a subsequent part of the alphabet. The subject of Galvanism, including *Animal Electricity*, will therefore be treated under the head of VOLTAIC ELECTRICITY, which will contain a complete view of Mr Faraday's discoveries, as well as of those which may be made by other philosophers before that article is required for the press.

GALWAY, a county in the province of Connaught, in Ireland, is bounded on the north by the counties of Mayo and Roscommon; on the east by those of Roscommon, King's County, and Tipperary; on the south by the county of Clare and by Galway Bay; and on the west by the Atlantic Ocean.

Its name is generally supposed to be derived from Gal, a stranger, or Gael, a merchant, and Iv, a territory, indicating a country inhabited by foreigners, or frequented by merchants. In the time of Ptolemy it was inhabited by the Auteri. In a later period it was divided into the districts of Clanconow, Hy-Maine, Maghullen, Lilanchia, Hy-Fiacrin-Aidne, afterwards Clanrickard, and Hy-Tartagh. In the commencement of the sixteenth century it was portioned out amongst a number of families or septs, of which the principal were the O'Flahertys and O'Maleys in the west; the Burkes and Berminghams in the north; the O'Naghtens, O'Kellys, and O'Dalys in the east; and the O'Heynes, the O'Maddens, and the O'Shaughnerrys in the north. It was made shire-ground by Elizabeth in 1569, and is now divided into seventeen baronies, of which Balymore and Dunmore are in the north; Athenry, Clare, Dunkellin, and Tyaquin, in the centre; Killian, Kilconnel, and Clonmacnoon, in the east; Longford, Loughrea, Leitrim, and Kiltartan, in the south; and Arran, Ballynahinch, Moycullen, and Ross, in the west. These are subdivided into a hundred and six parishes, and nine parts of parishes, the remaining parts of which are in some of the adjoining counties.

According to the ecclesiastical divisions of Ireland, the county contains a hundred and sixteen parishes, of which forty-nine are in the archdiocese of Tuam, thirty-seven in the diocese of Clonfert, twenty in Kilmacduagh, eight in Elphin, and two in Killala. The episcopal seats of the first three of these sees are in this county. The archdiocese of Tuam extends also over a large portion of Mayo and Roscommon, comprehending a space of seventy-seven miles by sixty-three, being the largest see in the country in extent of surface. The bishop's lands, whence he derives the greater part of his income, are estimated at 49,281 acres, and his revenue is returned as amounting to L.5549 per annum. In the town of Tuam there is a neat but small cathedral, which is used as the parish church. The Roman Catholic archbishop has just completed another cathedral, which is one of the most splendid fabrics for religious worship in Ireland. The see of Ardagh, in the county of Longford, is united to Tuam. The diocese of Clonfert, founded at the close of the sixth century, and extending into the county of Roscommon, is in the south-eastern part of the county. Its lands, together with those of Kilmacduagh, which were united with it in 1602, amount to 6555 acres, but no return of the amount of its income is extant. Part of the bishop's emoluments arises from what are called the *quarta pars*, being a portion, generally a fourth, of the tithes of certain parishes. The cathedral, which is also the parish church of Clonfert, is an ancient and capacious structure; the bishop's palace is in its immediate neighbourhood. The cathedral of Kilmacduagh is now the church of one of the parishes which constitute the deanry. According to the new episcopal arrangements, the dioceses of Killala and Achonry are to be united with Tuam on the next vacancy, and those of Clonfert and Kilmacduagh with that of Killaloe.

Galway is naturally divided by Lough Corrib into two great divisions, differing from each other in several striking points. The eastern division, which comprehends all the county except the four western baronies, rests on a limestone base, is convertible into good tillage land, and is, generally speaking, level; the western, comprehending the three last-named baronies (for that of Arran is a cluster of islands at the mouth of Galway Bay), has a substratum of granite, and is barren, rugged, and mountainous. The southern part of the former of these divisions is supposed by some to be a continuation of the Golden Vale of Limerick, so celebrated for its fertility, and produces the finest wheat, except in the region of the Slieveboghta Mountains, which form part of the boundary between this county and Clare. The northern part of the same division is also rich pasture and tillage ground, and beautifully diversified with hill and dale. Some of the intermediate country is comparatively barren; but those parts which would not repay the expense of tillage form excellent pasturage for sheep, which is the great staple commodity of the county.

The western division is divided into the three districts of Connemara, Tar-Connaught, and Joyce's Country, which correspond in boundary with the three modern baronies of Ballynahinch, Moycullen, and Ross. The name of Connemara is, however, often applied to the whole district, and signifies the Bays of the Ocean. Its highest mountains are the group of Benabola, or the Twelve Pins, which occupy a space of about five square miles, midway between Lough Corrib and Aghris Point, the most western projection of the county. Knockenhiggen, the highest of these, is 2400 feet high. The cliff to the south of Glen Ina presents a naked perpendicular cliff 1200 feet in elevation, over which a considerable sheet of water is precipitated. But this district, although mountainous, is not an elevated country; the surface of most of it is not a hundred feet above the level of the sea, rising from the edge of Galway Bay, in a gently sloping plain, to a height of not more than three hundred feet, where there are some hills about seven hundred feet high. Joyce's Country, more northwards, is an elevated tract, with flat-topped hills of from 1300 to 2000 feet high, with deep narrow valleys lying between them.

The rivers are few and small. The Suck, the largest, rises in Roscommon, and forms the eastern boundary, passing by Athleague and Ballynasloe, till it joins the Shannon at Shannon harbour. This latter river then forms part of the boundary to Mount Shannon. The Suck is joined by the Shevin and Ahascragh rivers. The Blackwater, which forms part of the northern boundary between Galway and Mayo, discharges itself into Lough Corrib. Near Shruil it sinks at once into the ground through an open called a shallow, and, after a short underground course, bursts forth again through several springs. The Carnamart passes through the southern baronies, and falls into Galway Bay. The Ballynahinch rises in the Twelve Pins Mountains, and after a short but rapid course empties itself into Birterbuy Bay.

The lakes are numerous. Lough Corrib extends from Galway town northwards thirty miles, affording a large scope for inland navigation. It communicates with the sea by the Galway river, but as its level is fourteen feet above high-tide mark, the fall is such as to prevent a water passage by the river from the bay to the lake. An attempt made to connect them by a canal having failed, is still pointed out under the name of Lynch's Folly. The lake is studded with many islands, some of them thickly inhabited. Near it is Lake Ross, which, with some smaller lakes, receives a large supply of water from streams, but has no visible outlet. In Connemara are a number of lakes extending nearly twenty miles from Lough Corrib to the sea, besides several others in other parts. About twenty-five of these are more than a mile in length each, and there are upwards of an hundred of a smaller diameter. The principal are lakes Ina, Derryclare, Ballynahinch, Poulagopple, and Fea. Lough Reagh, at the town of the same name, is more remarkable for scenic beauty than extent. Besides these perennial lakes, there are several low tracts which are covered with water during a great part of the year: they are called Turloughs. The largest is Turloughmore, extending from Tuam nearly to Clare Galway. Another of large size is near Rahasane. A few sheep are grazed on them during four months in summer, but they are unprofitable in winter. They are mostly of easy drainage; the main obstacle being the conflicting rights of the proprietors of the soil.

Galway enjoys the advantage of a very extended line of sea-coast, indented by numerous and safe harbours. Commencing at Killery Bay in the north, which separates the counties of Galway and Mayo, the first bay on the western coast is Ballynakill, capable of accommodating large ships, and sheltered by Truchelaun or Heath Island. Next in succession is Cleggan Bay, having Ennisbofin in its offing. From Cleggan to Aghris Cape, the most western point of the county, the shore is a low granite, outside of which are Crua, High and Friar Islands, and Omey Island on its south. Streamstown is a narrow inlet, within which are the inhabited islands of Tarbert and Innisturk. Ardbear harbour divides itself into two inlets, the northern of which is terminated by the rising village of Clifden; the latter has a fine salmon fishery. Mannin Bay, though large, is but little frequented by shipping. From Slyne Head the coast turns eastward to Roundstone Bay, having its entrance protected by the islands of Innisnee and Innislacken; here the whole British navy could lie in safety. Next in order is Birterbuy Bay, deep and safe, and near it is the island of Cruanakeely. Between it and Kilkerran Bay, the next in order eastwards, are the islands of Mason, Mynish, and Fynish, all inhabited; Elanmacdara and Cruanakeely, now a deer park. Kilkerran Bay has a most productive kelp shore of nearly a hundred miles, including its islands of Annaghvane, Garomna, Lettermore, Lettermullen, Knappagh, and Furnish, yet its mouth is but eight miles broad. Between Garonna and the main-land is Greatman's Bay, and close to it Costello Bay, the most eastern of those in Connemara. Next is the harbour of Galway, at the mouth of the River of Galway, having the village of Claddah on its western bank, inhabited by a most industrious and singular tribe of fishermen, by whom the town and neighbouring country is chiefly supplied with fish. At Oranmore the coast turns southwards, and presents the harbours of Rynville, Ardfry, Ballynacourty, Stradbally, Killeen or New Arran, Kinvarra, and Duras, where the county joins that of Clare. The whole of this coast, from Greatman's Bay eastward, together with the northern shore of Clare, to Blackhead, comprehends the Bay of Galway, the entrance of which is protected by the three islands of Arran, forming a distinct barony, and remarkable as well for many relics of ancient pagan and monastic institutions, as for the singular mode of life of the inhabitants.

The climate, though moist, variable, and exposed to frequent and violent gales from the west, is mild and salubrious. The country is subject to no diseases except those incident to a population not attentive to domestic neatness, and frequently in a state of great destitution. Frost or snow seldom remains long on the western coast, and cattle of every description continue unhoused during the winter.

The boundary line between the limestone and granitic district is easily discernible to an intelligent eye, by the diminution of the verdant hue which marks the latter. The high road from Galway to Oughterard nearly marks the division. All the country to the north and east of this limit is limestone, all to the south and west granite, excepting some detached masses of primitive limestone between Oughterard and Clifden, and some scattered portions of other minerals, of great variety of appearance. The component rock of Benebola is quartz, in general distinctly stratified, or at least schistose. The position of its beds is various. Towards the western shore they are vertical, easily splitting by intervening mica plates, and affording a good building stone. Limestone occurs in some places along the foot of these mountains, where also is some green serpentine, which is conveyed to Galway and elsewhere for ornamental purposes. Round the basis of this group are also gneiss and mica slate, with bands of hornblende and primitive mica. Along the north side of Lough Corrib to Ballynakill the mica slate and hornblende rise into mountains, and the limestone disappears. From Lough Mask to Killery Bay is a transition country of greenstone and grauwacke slate, covered by the old red sandstone or glomerate. The hill of Glan on the shore of Lough Corrib exhibits, in a small compass, all the formations which occur in the district. The western end is quartz; the north-eastern side mica slate; the middle is penetrated by beds of mica slate, containing hornblende and granular mica covered by thick beds of pyritous greenstone. On the south and east are granite and syenite, which runs under the sandstone, conglomerate towards Oughterard, and this again passes under the flœtz limestone, which, passing Lough Corrib, occupies the greater part of Connaught and Leinster. Along the borders of the flœtz limestone is a series of vast caverns, usually traversed by subterraneous rivers, a phenomenon which, though not of unfrequent occurrence in limestone countries, is peculiarly striking here. The succession of the stratified rocks may be distinctly seen at the water-fall at Oughterard. A fine gritstone, highly valued for making mill-stones, is raised near Dunmore. Crystalline sand, of a superior quality for scythe boards, occurs at Lough Coutra; and mowers come for it from great distances. Lead has been found near Lough Corrib and other parts of Connemara, manganese at Slieve-an-oir in the south. Iron was raised at Woodford, and smelted until the timber was exhausted. The mountains of Slieveboghta, which separate Galway from Clare, are siliceous. A beautiful black marble, without spots or flaws, and susceptible of a high polish, is raised near the town of Galway in large quantities, particularly for chimney-pieces. Mineral spas, mostly chalybeate, are abundant. That at Kingston was pronounced by Kirwan to be one of the best in Europe. At the village of Quose is a well which instantly kills poultry that drink of it. A spa at Oughterard draws many invalids to that town. Others at Athenry, Woodbrook, Rathglass, Killimore, and Abbert, are equally prized in their respective neighbourhoods.

The inhabitants of Galway are not distinguished by any striking peculiarities from those of the rest of the province. It is known that, on the settlement of Ireland after the Restoration, great pains were taken to remove to Connaught such of the native Irish as had been allowed to retain their property, insomuch that many proprietors of this description, who had resided in other provinces, were compelled to exchange their properties for lands in it supposed to be of equal value with what they were forced to surrender. They were also prohibited from settling in any of the corporate towns, or within a mile of the sea-coast, the boundary of which was called the mile-line. Thus cooped up, and debarred all opportunities of intermixing with strangers, it is not surprising that they have retained many peculiarities of appearance and manners. But these peculiarities are not confined to this county. One very remarkable variety of the species is exhibited in the fishermen of Claddagh. This village is supposed to have been the germ of the now populous and once commercial town of Galway. The inhabitants form a community of about 1100 souls, who intermarry among one another, and jealously resist the residence of strangers. The men are all fishermen. This is their sole occupation. They are governed by a mayor, elected by themselves, whose only mark of office is the white sail of his boat, and a flag at its mast-head; but to him they pay implicit deference. He regulates the time of the sailing of the fishing fleet, and its movements when at sea. At home the women are mistresses; the moment the boats' cargoes are unloaded, the whole is transferred to them; they make the sales and spend the produce, their husbands being fully satisfied with the liberal allowance of spirits and tobacco they receive from them; but on their fishing expeditions no ardent spirits are suffered in their boats; their stock then consists solely of potatoes, oaten bread, fire, and water. Their language is Irish, which they speak with a harsh discordant accent. Literary education is almost unknown among them. The dress of the men consists of three flannel vests under a fourth of white dimity, a blue rug jacket, and blue plush breeches never fastened at the knees, blue worsted stockings, a horizontal-brimmed hat, and a red silk neckerchief. Among the women, the matron's dress is a blue mantle, a red body gown and petticoat, and a silk handkerchief on the head. Unmarried women are known by their muslin caps trimmed with the richest lace; ribbons are not worn. Females of all ages are remarkable for attention to neatness, both in their persons and household. It is scarcely necessary to add, that their religion is almost exclusively Roman Catholic, there being but one or two exceptions. Marriages are generally preceded by an elopement, and followed by a boisterous merrymaking. The possession of a boat, or at least a share of one, is deemed the qualification requisite to justify a young man in taking upon himself the charge of a family. The great village festival is celebrated on St John's day in midsummer, when all the young men of the village march through Galway in uniform white jackets, with silken sashes, and flowers in their hats, carrying flags and standards with fanciful devices, and preceded by two or three of the most arch wags among them, disguised as mummers. The day terminates with bonfires, dancing, and village merriment. St Patrick's day is also a season of peculiar festivity, which continues for two or three days.

The population of the county was as follows at the periods stated in the under-cited authorities:

1760	De Burgo	82,188
1792	Beaufort	142,000
1812	Parliamentary return	261,000
1821	Do.	309,599
1831	Do.	394,287

According to these calculations, the population has increased with extraordinary rapidity, having nearly tripled in the course of forty years.

Notwithstanding its great extent and proportionate population, the county sent but eight members to the Irish parliament; two for the county at large, and two each for the boroughs of Galway, Athenry, and Tuam. By the act of Union the number of borough members was reduced to three, two for the county and one for the town of Galway. By the reform act this number was increased to four; the county and town now returning two members each. The constituency previously to the disfranchisement of the forty-shilling freeholders was the most numerous of any county in Ireland. The changes produced on its numbers by the Catholic relief act, and by the reform act, will best appear by the following table:

	L.50.	L.20.	L.10.	40s.	Total.
1829	828	274	950	32,055	34,107
1830	897	299	1812	...	3,008
1831	326	191	2540	...	3,057

From the population returns of 1821, and those of the commissioners of education in 1824–26, the state of education was as follows:

	Boys.	Girls.	Sex not ascertained.	Total.
1821	7,690	3161	...	10,851
1824–26	11,874	6487	463	18,824

Of the number of pupils stated in the latter return, 1471 were of the established church, and 17,090 Roman Catholics. The number educated by grants of public money was 1600, of those educated by the contributions of societies or individuals 3626, and of those who paid for their instruction 13,598. The average proportion of Protestants to Catholics, estimated from the relative numbers of the children of each persuasion receiving scholastic instruction, was as 1 to 11½ nearly.

The eastern part of the county produces the best wheat, the growth of which requires the preparatory culture of potatoes. Oats are frequently sown after potatoes in moory soils less adapted for wheat. Manure is generally abundant, but most so in the western districts, which do not admit the growth of wheat. The flat shores of the bays there are formed of coralline sand, and the quantities of sea-weed thrown up after storms affords a copious supply of vegetable manure. Limestone gravel and marl is to be had in most other parts. When this substance is applied to reclaimed bog, the admixture of animal manure, however small the quantity, is said to render it much more effective. When a sufficient quantity of manure for potatoes cannot be had, the usual practice is to pare and burn the surface, for which purpose a broad and sharp spade, with a considerable bend in the blade to prevent the necessity of stooping, is made use of. Potatoes are still planted in ridges by the small farmers, who make much use of spade culture, particularly in the upland districts, where the ruggedness of the surface is unfavourable to the application of the plough. They also pay great attention to the weeding of their crops. When sea-weed is used for potato ground, it is previously dried, but used fresh in preference to being thrown up in heaps to putrefy. In many places on the sea-shore fine early potatoes are raised in several feet of sea-sand, manured with sea-weed, which is succeeded by barley. Oxen are little used in husbandry, excepting by a few extensive farmers. The plough is clumsy and defective. The fences most in use are formed of the stones collected from the surface, and raised to the height of five or six feet in dry walls, broad at base, and narrowing upwards. Thrashing-mills are uncommon; carts are not generally employed, as the small cars are cheaper in construction, and more easily worked in the mountainous parts. Slide-cars are still in use in some places, as being the only kind fit to draw loads down steep hills. The chief markets for grain are Galway, Loughrea, Tuam, Ballynasloe, Gort, Eyrecourt, and Mount Bellew. Flour-mills are numerous. Those parts of the eastern district less fitted for grain are employed in pasturage. Heathy sheep-walks occupy a very large tract between Monivæ and Galway. An extensive range from Athenry, stretching to Galway Bay at Kinvarra, is also chiefly occupied by sheep. Tracts of coarse moory ground are attached to many farms, which only require draining, a practice little known or encouraged to repay the labour of tillage amply.

A breed of small hardy horses is raised in Connemara; but, in consequence of the introduction of stallions of large size, it is declining. The breed of black cattle is chiefly long-horned. A great improvement has taken place in sheep as to the carcass, but to the deterioration of the fleece. Some of the old stock of red deer are occasionally seen, and hunted down or shot. The great fairs for cattle and wool are held at Ballynasloe, in May and October. Dairies on an extensive scale are unknown; but excellent butter is made in the neighbourhood of Galway. In Connemara cows are very frequent with the cottage farmers.

Manufactures are not carried beyond the demand caused by the domestic consumption of the people. Coarse friezes, flannels, and blankets are made in all parts, and sold largely in Galway and Loughrea. Connemara has been long celebrated for its woollen stockings. They are knit by the hand, and have a softness and elasticity superior to that of the woven article; but they are slight, and therefore give but little wear. The fineness of the wool is one great cause of their excellence. The women adhere to a very primitive practice in the manufacture. When about to commence a pair, the operator goes to the mountain, clips off from the living animal the quantity she deems sufficient, and works it up. Hence it is noways uncommon to see a sheep with one side shorn, or a part of the neck and shoulders bare of wool, according to the judgment or fancy of the stocking knitter. Coarse linen, of a narrow breadth, called bandle linen, is also made for home consumption; but sufficient attention to the spinning and reeling of the yarn, and to the weaving of the cloth, is wanting to entitle it to appear to advantage in foreign markets. Coarse sacks of tow, for packing wool and bacon for exportation from the great provision marts of the south, are in much demand. The manufacture of finer linens and diapers was attempted, but with little success. That of kelp is one of the great sources of profit on the western shores. It was introduced about the year 1700. At first the kelp sold as low as from 14s. to 16s. a ton, but rose progressively until it advanced to L.16 a ton in 1810; but since that time it has fallen, both on account of the increased supply from other quarters, and from negligence or fraud in the preparation of the home-made article. The price is now about L.4 the ton, and the quantity manufactured about 10,000 tons. Of the minor manufactures, marble is wrought for domestic and sepulchral purposes in Galway. Coarse pottery and tobacco pipes are made in the same town, and at Creggs and Dunsandle. Felt hats and coarse straw bonnets are made in several places. Feathers are brought in great quantities from the islands of Arran, where they are procured from the puffins and other sea-fowl that frequent the cliffs on the coasts. They are caught by men trained to the practice, who are let down at night from the projecting crags above, by means of a rope tied round their waist, to the haunts of the birds; and on supplying themselves with all they can capture, they are hauled up again in the morning. Sea fowls' eggs are collected in large quantities in the same manner.

Amongst the relics of antiquity are the round towers of

Ardrahan, Ballygaddy, Kilbannon, Kilmacduagh, Meelick, and Murrough. The last-named of these is of very small dimensions; that of Kilmacduagh, which is still fifty feet high, inclines seventeen feet from the perpendicular. Raths are numerous, and several cromleachs are still to be seen in good preservation. The ruins of monastic buildings are also numerous. That of Knockmoy, about six miles from Tuam, contains the monument of O'Connor, one of the kings of Ireland. It is adorned with fresco paintings, which are still in a state of some preservation. Ancient castles are likewise numerous; some have been kept in repair, and are still inhabited; but by much the greater number are in ruins. The castle of Tuam, built in 1161 by Roderic O'Connor, king of Ireland, is said to have been the first building of this description of stone and mortar in Ireland. The remains of a round castle, a form of building very uncommon in the military architecture of the country, is to be seen between York and Kilmacduagh.

Galway, the county town, is also a county in itself, having an exclusive local jurisdiction, which extends two miles on every side except the south. It stands on the northern shore of the Bay of Galway, on the eastern bank of the river of the same name, and is enclosed on the land side by the baronies of Clare, Dunkellin, and Moycullen. It is supposed by some to be the Nagnata or Naguata of Ptolemy. It certainly was considered a position of much importance from the earliest period, as in the divisions of the island into north and south, at first made by the descendants of Heremen, and afterwards repeated by Conn and Eogan, it was fixed upon as the eastern extremity of the line of demarcation, which proceeded eastwards to Dublin. Little, however, is known of it until after the arrival of the English, at which time it was under the protection of O'Flaherty, who possessed the adjoining district to the west. On the extinction of the native dynasty of the O'Connors, the town fell into the hands of the De Burgos, the head of a branch of which, under the name of M'William Eighter, long governed it by magistrates of his own appointment. After it had been secured by walls, which began to be built in 1270, it became the residence of a number of enterprising settlers, through whom it attained a position of much commercial celebrity. Of these settlers the principal families, fourteen in number, are still known by the name of the Tribes of Galway. Their names are preserved in the following distich :—

Athy, Blake, Bodkin, Browne, Deane, Darcy, Lynch,
Joyes, Kirwan, Martin, Morris, Skerrett, French.

The tribe whose name is not included in the rhyme was called Ffont. These families became so closely connected by intermarriages, that dispensations are frequently requisite for the canonical legality of marriages among them at present. The town rapidly increased from this period in wealth and commercial rank, in this respect far surpassing the rival city of Limerick. Richard II. granted it a charter of incorporation with liberal privileges, which was confirmed by his successor. It had the right of coinage by act of parliament; but there is no evidence to show that it exerted the privilege. Another charter, granted in 1545, extended the jurisdiction of the port to the islands of Arran, permitted the exportation of all kinds of goods except linens and woollens, and confirmed all the former privileges. The commercial prosperity of the town, which had been steadily advancing under the protecting favour of the government, received its first check from an unfavourable decision of the Court of Chancery, respecting the prisage of wine; a toll paid by every sea-port to the head of the Ormond family, in right of his office of chief butler to the king, and from the payment of which Galway claimed an exemption which had been hitherto acquiesced in. Wine was the great staple of commerce. The payment of prisage, which consisted of two pipes of wine from every vessel discharging at the port, was a heavy drawback upon its profits. But soon after, its municipal privileges were extended by a charter from James I., whereby the town, and a district of two miles round in every direction, were formed into a distinct county, with exclusive jurisdiction and a right of choosing its own magistrates. During the civil wars of 1641, the town took part with the Irish, and was surrendered on articles to the parliamentary forces under Sir Charles Coote; after which the ancient inhabitants were mostly driven out, and their property given to adventurers and soldiers, chiefly from England. On the accession of James II. the old inhabitants entertained sanguine hopes of recovering their former rights. But the successes of King William soon put an end to their expectations; and the town, after undergoing another siege, again capitulated to the force brought against it by General Ginkell, on condition of a safe conduct for the garrison to Limerick, pardon and the protection of property and civil rights to the townsmen, and the free exercise of their religion in private. The penal statutes passed by Queen Anne against the Roman Catholics in general rendered the latter clause of the capitulation nugatory, and exposed that portion of the population which stood in need of its protection to much hardship, particularly on the breaking out of the rebellions of 1715 and 1745 in Scotland. During the period of volunteering, Galway embodied a corps of eight companies; and in the subsequent insurrection in 1798, the merchants, at an hour's notice, furnished General Hutchinson with fifteen hundred guineas, to enable him to join Lord Lake at Castlebar, whither the yeoman company of the town accompanied him, and took part in the battle at that place. In the beginning of the present century the walls were thrown down, and buildings erected on their site. Several streets have also been carried out eastwards, to which the name of the New Town is given.

Galway is governed by a mayor, two sheriffs, the free burgesses, and the commons, with a recorder, town-clerk, and other subordinate officers. The mayor is permitted to have a sword of state carried before him. The right of returning members was exercised at an early period. By the act of union the number of representatives was reduced to one; but the other was restored to it by the reform act. The population in 1821 amounted to 27,775, and in 1831 it had increased to 33,120.

In its ecclesiastical arrangements the town formed part of the ancient diocese of Enachdune or Annaghdown, which was incorporated in 1314 with the archdiocese of Tuam. But in 1484 it was erected into an exempt jurisdiction by the name of the wardenship of Galway, to be governed by a warden and eight vicars, chosen by the corporation; the parishes of Furanmore, Moycullen, Skreen, and Ballenclare, were united to the wardenship. At the Reformation it was deprived of much of its property; and since that time there have been two wardens, a Protestant, nominated by the corporation, and a Catholic, chosen by the ancient inhabitants or tribes.

The town is situated on the extremity of a projecting neck of land, rising with a gentle acclivity between the river and the sea. The space within the walls formed an oval of about 3426 square perches, covered with strongly built houses, chiefly in the antique Spanish fashion, being square, with a court in the centre, and a gateway opening into the street. St Nicholas' Church is the most remarkable building in the town. It is cruciform, 152 feet long by 126 broad, having a steeple rising over the nave, and the side aisles separated from the centre by Gothic pillars. Its interior can accommodate upwards of 5000 individuals. There are several antique monuments in it. The exchange, or tholsel, near the church, consists of an open corridor, 90 feet long by 28 broad, with a front of arches supporting an upper story, in which are apartments for holding the town courts, and for other public purposes. The county court-house is an elegant modern building, having ample accommodations for all the purposes of its erection; and near it are the county and town prisons, both modern structures; the former being considered as the best constructed prison in the province. The barracks are small buildings detached from each other. The town has also a county infirmary, in which between 800 and 900 patients are annually relieved, and also a fever hospital. A grammar school, under the board of Erasmus Smith, is in the immediate neighbourhood of the town; and a charter-school was opened in 1750, but closed in the year 1798; the building is now a nunnery. It has been succeeded by a public school for the education of 150 indigent children. The meat and fish markets are convenient, well kept, and plentifully supplied. The small mutton from the island of Arran is peculiarly esteemed for its flavour. The river is crossed by two bridges; the one near its mouth was built in the year 1342, and, after setting at defiance the impetuosity of the current for five centuries, appears sufficient to brave it for as many more; the other, higher up the stream, an elegant modern structure, connects the county court-house and the jail. A literary association, called the Amicable Society, has collected a library of some extent, to which a news-room is attached. There are several charitable institutions for the relief of disease, the maintenance of the aged and impotent, and the care and instruction of orphans.

Galway, though much reduced in the scale of mercantile importance, is still an extensive exporting town, particularly of grain, flour, and kelp. For some years the average export of grain was 4000 tons. Large quantities of flour are manufactured in the town and its vicinity; much of it is transported to Dublin by the canals. The imports are flax-seed, timber, hemp, tallow, iron, and coal. The port duties are little more than sufficient to defray the expenses of the establishment employed in their collection.

Amongst the eminent characters to which this town has given birth were, Patrick Darcy, the author of the argument for the independence of Ireland before the House of Commons in 1641; John Lynch, author of *Cambrensis Eversus*, and other tracts on the antiquities of the country; Roderic O'Flaherty, author of the *Ogygia*, who died in 1718; Sir George Staunton, secretary to Lord Macartney in India, and author of the account of that nobleman's embassy to Pekin; Walter Blake Kirwan, celebrated as a popular preacher in Dublin; and Richard Kirwan, the chemist and mineralogist.

The other towns of much notoriety are Ballinasloe, on the borders of Roscommon, the great cattle and wool staple for Ireland, where fairs are held twice a year, in May and in October, at which immense droves of black cattle and flocks of sheep are disposed of; (the grand canal from Dublin terminates here); Athenry, a town of considerable importance in the earlier periods of Irish history; and Loughrea, beautifully situated on the borders of a small lake of the same name.

GAMA, Vasco de, born at Synis, a sea-port in Portugal, was admiral of the fleet which first doubled the Cape of Good Hope in 1497, and arrived on the coast of India. The historians who have transmitted to us his discoveries, have contented themselves with informing us of the facts connected with his first voyage, and the establishment of the Portuguese in India, but they have left us in ignorance of the details of his private life. This is the more to be regretted, as Gama is one of those men who, by important discoveries, have contributed to the prosperity of their country and the increase of human knowledge. The progress of the art of navigation, and the desire of exploring our globe, excited by the prospect of gain, had about this time taken possession of the minds of men; and the success of the expedition of Christopher Columbus had given a fresh stimulus to this spirit of adventure. This extraordinary man had taught navigators the means of conducting themselves with safety across the ocean; and his example had encouraged them to brave all dangers. The Portuguese who, under the guidance of Prince Henry, had been the first to turn their views in this direction, observed with jealousy that the fruits of their researches were about to enrich the Spaniards, and they sought to indemnify themselves by pursuing, with more activity than ever, their discoveries on the side of Africa, in the hope of passing to the south of that continent, and penetrating into India, or into the kingdom of Abyssinia, of which they had acquired some notion by the relations which they maintained with the Moors. As they believed that the inhabitants of this last kingdom were Christians, they gave to the sovereign thereof the name of *Prester John*, by which people had hitherto designated a powerful prince whom they believed to be Christian, without, however, knowing where his dominions were to be found. It appears, indeed, from what has been said on the subject, that this name has been applied to the great Khan of Tartary, and to the Grand Lama of Thibet, as well as to the king of Abyssinia. The existence of this Christian king was confirmed by Peter of Covilham, who, in 1487, had set out with Alphonso de Paiva, in order to reach India by the Red Sea. The latter, however, proceeded to Abyssinia, where he remained some time, but he died soon after his return to Cairo. Having visited Goa, Cananor, Calicut, and acquired some knowledge of the coast of Sofala, situated in the canal of Mozambique, Covilham, on returning to Cairo, found the narrative of Paiva's voyage, which he transmitted to Portugal, together with an account of what he had himself done. He descended the Red Sea a second time, touched at Ormus, and lastly penetrated into Abyssinia, where he was detained during twenty years. His first voyage had been conceived on a very wise plan; and the information which he procured put him in a condition to enter the Indian Seas, with the certainty of deriving great advantages from such an enterprise, if it should only be found practicable to pass to the south of the continent of Africa. In fact, some knowledge had already been obtained of great cities in India, abounding in wealth derived from commerce; and it was also known that, on the eastern coast of Africa, at a great distance from the places where the Indian Sea might be entered, were commercial nations, amongst whom it would be possible to refit and procure pilots for proceeding further. Bartolomeo Diaz, having sailed from Lisbon in 1486, proceeded in search of the southern extremity of Africa, and had the good fortune to discover it. The storms which he had encountered, however, induced him to denominate the promontory by which the African continent is terminated, the Cape of Tempests; but this name was changed by the king of Portugal into that of the Cape of Good Hope, with the intention of obviating the unfavourable impression likely to be produced by a sinister name. Diaz returned to Lisbon in December 1487. There seemed now to be no obstacle calculated to prevent navigators entering the Indian Sea; but daring enterprises remain long in suspense, until men are found capable of carrying them into execution. It was not until five years after the discovery of the New World by Columbus, and ten years after that of the Cape of Good Hope by Diaz, that Emanuel king of Portugal resolved to send a fleet into India, and chose as its commander a gentleman of his own household, named Vasco de Gama, already known by his prudence, firmness, and ability in navigation.

The expedition destined for this great enterprise consisted of three vessels, having on board as crews a hundred and sixty men. Vasco de Gama sailed from the Tagus on the 8th of July 1497. He first shaped his course towards

Gama.

the Cape de Verd Islands, which he doubled, and making his way to the southward, anchored in the bay of St Helena, situated on the western coast of Africa, at a little distance to the north of the Cape of Good Hope. On the 16th of November he quitted this bay, and in two days after arrived at the extremity of Africa; but in attempting to make his way to the eastward, his little squadron had to contend with the south-eastern monsoon, which blows almost continually during that season of the year, and generally with great impetuosity. His crews, discouraged by the boisterous weather, attempted to force him to return; but he managed to allay their mutinous despondence, and by his firmness succeeded in overcoming all obstacles. He made to the eastward along the southern coast of Africa, stood in to the bay of St Blaise, and, on the 17th of December, arrived at the rock of Cruz, where Diaz had terminated his discoveries. It is at this point where the eastern coast of Africa begins to trend towards the north, and here the Portuguese for the first time entered the Indian Sea. Vasco de Gama, whose intention it was to go in quest of the countries which had been visited by Covilham, kept in sight of land; he proceeded northward, and several times sent his people to visit places where he observed inhabitants. He also went ashore himself as often as the population appeared considerable; but not finding any people who could give him information, he continued his voyage, passed the Cape of Currents, situated nearly under the tropics, and advanced beyond the coast of Sofala, including the city of that name, where Covilham was believed to have touched, but without discovering any establishment which could induce him to stop. At length, in one of the first days of March 1498, he anchored before the city of Mozambique, then inhabited by Moors or Mahommedan Arabs, who lived under the authority of a prince of their religion, and carried on a considerable trade with the Red Sea and the Indies. The hope of trafficking with the new-comers procured the Portuguese a favourable reception; but as soon as it became known that they were Christians, snares were laid for them, with the intention of massacring them. Obliged to withdraw from the perfidy of these fanatics, Gama set out from Mozambique, and sailed northward, along the coast for Quiloa, conducted by a pilot of Mozambique, whom he had carried along with him; but having approached the land to the north of that city, the currents prevented him from returning southward, and accordingly he veered away towards Monbaze, still following the line of the coast. This city, which was better built than Mozambique, and carried on a more extensive commerce, was also inhabited by Mahommedan Moors, who evinced the same hostility towards the Portuguese as those of Mozambique had done. Gama therefore withdrew without obtaining any thing, and advancing eighteen leagues further, reached Melinda, which is only three degrees south of the equator. Here he was more fortunate. Although this city was also peopled with Mussulmans, commerce appeared to have softened their manners; the prince of the country gave the strangers a most favourable reception, and went on board the Portuguese squadron, where he was received with the greatest honours. At this place Gama obtained a pilot, one of the most skilful navigators of the country, called Malemo-Cana, an Indian of Guzerat, to conduct him to Calicut; and having left Melinda, he, in twenty-three days, reached the coast of Malabar, and cast anchor before Calicut on the 20th of May 1498. Here Gama, as his custom was, sent ashore several of the convicts he carried along with him, accompanied by a Moor who happened to be on board his fleet, and who fortunately discovered a countryman of his own who was then in attendance at the court of Calicut. They were favourably received by the prince or zamorin, who granted the Portuguese permission to enter the port, and consented to receive Gama with the same honours which he rendered to the ambassadors of the greatest monarchs. But this good understanding was soon interrupted. The Mahommedan Moors and Arabs, inflamed with a fierce and bigoted hatred of all Christians, represented the strangers to the zamorin as pirates, who came to disturb the tranquillity of his dominions, with the intention of pillaging them. Distrust and suspicion were thus excited in the mind of the prince; and at length a plot was formed to burn the Portuguese ships and massacre their crews. Apprised of this design by Malemo-Cana, the pilot who had conducted him to Calicut, Gama, who had gone ashore, sent intelligence to his brother Paul de Gama, to be on his guard, and at the same time to keep a considerable offing; and having, by a rare mixture of firmness and address, managed to withdraw his people in safety, he immediately set sail, and having repaired his vessels at the Angedive Isles, situated on the coast to the north of Calicut, he proceeded on his return to Europe. In passing Melinda, he took on board an ambassador of the prince of that country, the only friend whom the Portuguese had yet acquired in India; and coasting along the African continent in the opposite direction to that which he had followed in the voyage outwards, he doubled the Cape of Good Hope in the month of March 1499, and arrived at Lisbon in the September following, after an absence of more than two years. The king, Emanuel, received Gama with the greatest magnificence, celebrated his return with festivities, gave him the title of Dom, and created him admiral of the Indies.

A second Portuguese fleet was immediately fitted out, and sent to India under the command of Alvarez Cabral, who succeeded in establishing a factory at Calicut; but in his absence the Portuguese were massacred at the instigation of the Moors. Cabral, however, managed to obtain the friendship of the king of Cochin, with whom he contracted an alliance; but the reports made by him on his return convinced Emanuel that he would never succeed in establishing the Portuguese power in India except by open force. A more considerable armament was accordingly fitted out, consisting of twenty vessels, which were divided into three squadrons, the most numerous of which, consisting of ten ships, sailed under the conduct of Gama, whilst the two others, of five each, under the orders of Vincent de Sodre and Stephen de Gama, left Portugal separately, with instructions to effect a junction in India. In this expedition Gama spread the terror of the Portuguese name along the whole eastern coast of Africa; formed establishments at Mozambique and Sofala; punished the zamorin and people of Calicut for their meditated treachery during the former voyage; renewed the treaty which Cabral had concluded with the king of Cochin; and, in conjunction with Albuquerque, founded the port and factory of Cochin, the first of the Portuguese settlements in India, and the cradle of their power in the east. They began by violence, and nothing but the heroic and enterprising spirit with which they were animated could have enabled them to perform the prodigies of valour by which they signalised their proceedings, and triumphed over every effort made for their expulsion. Gama left the squadron of Vincent de Sodre on the coast of Malabar, and returned to Lisbon, where he arrived on the 20th December 1503, with thirteen ships. His title of Admiral of the Indies was now confirmed, and the king added to it that of Conde de Videgueyra.

Vasco de Gama, covered with glory, now remained in absolute repose during the long period of twenty years. At length the court of Portugal having, in 1524, come to the resolution of appointing a viceroy of India, Vasco de Gama was the first person invested with that dignity. But he died soon after his arrival at Cochin, where his body was deposited until 1558, at which period it was transported to Portugal, where John III. caused the greatest honours to be paid to it. Gama was a man of the middle height, extremely corpulent, and with a red and inflamed visage, which, under the excitement of passion, assumed an expression of downright ferocity. In too many instances, particularly during his second voyage, he allowed himself to be betrayed into an excess of cruelty as impolitic as it was unrelenting; but it is nevertheless just to add, that this may in part at least be attributed to the harsh and severe manners of the times in which he lived. The history of his discovery of India has been transmitted to us by Barros, in his Decades, printed at Lisbon in 1628, and also by Hernan Lopez de Castanheda, in an extended account of the conquests of the Portuguese in the East Indies. In the Collection of Ramusio, in the works of Faria y Sousa, and in the history of Lafitau, the reader will also find detailed narratives of this memorable event in the Portuguese annals. All the world knows that Camoens made it the subject of his Lusiad. (A.)

GAMBIA, a large river of Negroland, in Africa, running from east to west to the Atlantic Ocean.

GAMBIER'S ISLANDS, a group of small islands in the South Pacific Ocean, discovered by Captain Wilson of the Duff in May 1797. They extend about five or six miles in length. An elevated mountain in the middle is in Long. 225. E. Lat. 23. 12. S.

GAME, in general, signifies any diversion or sport which is performed with regularity, and conducted according to certain rules.

Games are usually distinguished into those of exercise and address, and those of hazard. To the first belong chess, tennis, billiards, and others; to the latter those performed with cards or dice, as backgammon, ombre, piquet, whist, and others.

GAMES, in *Antiquity*, were public diversions, exhibited on solemn occasions. Such were the Olympic, Pythian, Isthmian, and Nemean games, among the Greeks; and the Apollinarian, Circensian, Capitoline, &c. games, among the Romans.

GAME LAWS. The term *game*, in a large sense, seems to comprehend all animals obtained by fowling and hunting, animals *feræ naturæ*, as contradistinguished to tame animals, such as horses, cows, sheep, and the like, which do not fly the dominion of man, but generally keep within the same pastures and closes; but in its stricter acceptation it applies only to those wild animals which the *game laws* and other arbitrary constitutions have distinguished by that appellation.

The view taken on this subject by Judge Blackstone is this: By the law of nature, says he, every man, from the prince to the peasant, has an equal right of pursuing and taking to his own use all such creatures as are *feræ naturæ*, and therefore the property of nobody, but liable to be seized by the first occupant; and so it was held by the imperial law even so late as the time of Justinian. But this right, like others of the same kind, may be restrained by positive laws, and we find has been so restrained by the municipal laws of many nations. Yet however defensible these provisions may in general be, on the footing of reason, or justice, or civil policy, we must notwithstanding acknowledge, that in their present shape they owe their immediate origin to slavery, having been introduced into Europe along with the feodal system. On the Norman conquest, the right of pursuing and taking such animals as were accounted *game* was held to belong to the king, or to such only as were authorized by him. And this, the learned commentator says, as well upon the principles of the feodal law, that the king is the ultimate proprietor of all the lands in the kingdom, as upon another maxim of the common law, that these animals are *bona vocantia*, and, having no other owner, belong to the king by his prerogative. Wherefore, he concludes, all persons, of what property or distinction soever, who kill game without the king's grant, are guilty of encroaching on the royal prerogative; and those persons who do so without having what is called a qualification, are guilty not only of the original offence, but also of the aggravations created by the statutes for preserving the game; which aggravations are so severely punished, and those punishments so implacably inflicted, that the offence against the king is seldom thought of, provided the miserable delinquent can make his peace with the lord of the manor.

The doctrine thus promulgated, novel and startling as it was, maintained itself long on the mere name and reputation of the author. It is now, however, admitted to be incorrect. The law of Canute, noticed by Blackstone, "quilibet homo dignus venatione sua, in sylva et in agris sibi propriis et in dominio suo," was confirmed by many succeeding kings; and there is no instance, civil or criminal, in which a person has been sued or prosecuted on behalf of the king for taking game, unless he took it out of some privileged place. On the contrary, there is a current of dicta and decisions showing that owners of land have uniformly been considered as having a local property in game, and a right to take it whilst upon their own land.

However, the legislative provisions are in restraint of the common law right; and these provisions were till lately many and various, and not a little obscure and intricate. But in October 1831 an important act was passed to amend the laws of England relative to game, namely, 1 and 2 Gul. IV. c. 32, which repealed about thirty previous statutes on the subject, and, excepting as to game certificates, may be looked upon as containing nearly the whole law in relation to game.

This statute of William begins by enacting that the word *game* shall, for all the purposes of the act, be deemed to include hares, pheasants, partridges, grouse, heath or moor game, black game, and bustards. It then sets out the *days* and *times* during which game shall not be killed, declaring that if any person shall kill or take any game, or use any dog, gun, net, or other engine or instrument for the purpose of killing or taking any game on a *Sunday* or *Christmas day*, he shall, on conviction, forfeit and pay, for every such offence, such sum of money, not exceeding L.5, as to the justices shall seem meet, together with the costs of conviction; and prohibiting, under a penalty, the killing or taking any *partridge* between 1st February and 1st September; *pheasant* between 1st February and 1st October; *black game* (except in the county of Somerset or Devon, or in the new Forest of Southampton) between 10th December and 20th August, or in the above excepted places between 10th December and 1st September; *grouse* or red game between 10th December and 12th August, or any *bustard* between 1st March and 1st September; and it further declares, that if any person, with intent to destroy or injure any game, shall at any time put any poison or poisonous ingredient on any ground, whether open or enclosed, where game usually resort, or in any highway, every such person shall, on conviction, forfeit and pay such sum of money, not exceeding L.10, as to the justices shall seem meet, together with the costs of conviction; and further, that if any person *licensed* to deal in game shall buy or sell, or knowingly have in his house, shop, stall, possession, or control, any bird of game after the expiration of ten days (one inclusive and the other exclusive) from the respective days in each year on which it shall become unlawful to kill or take such birds of game respectively as aforesaid, or if any person not being licensed to deal in game, shall buy or sell any bird of game after the expiration of ten days from the respective days in each year on which it shall become unlawful to kill or take such birds of game respectively as aforesaid, or shall knowingly have in his house, possession, or control any bird of game (ex-

Game Laws

cept birds of game kept in a mew or breeding place) after the expiration of forty days (one inclusive and the other exclusive) from the respective days in each year on which it shall become unlawful to kill or take such birds of game respectively as aforesaid, every such person shall, on conviction, forfeit and pay, for every head of game so bought or sold, or found in his house, shop, possession, or control, such sum of money, not exceeding L.1, as to the justices shall seem meet, together with the costs of conviction. The act then provides that the same, except as therein mentioned, shall not affect or alter the laws respecting *game certificates;* and declares that all regulations and provisions contained in any act relative to game certificates, as far as they relate to gamekeepers of manors, and to the amount of duty for game certificates to be charged upon or in respect of gamekeepers of manors in the cases specified in such act, shall apply to all gamekeepers of lands appointed under this act; and it further declares, that every person who shall have obtained an annual game certificate shall be authorized to kill and take game, but subject to the law of trespass, and provided always that no game certificate on which a less duty than L.3. 13s. 6d. is chargeable under the acts relating to game certificates shall authorize any gamekeeper to kill or take any game, or to use any dog, gun, net, or other engine or instrument, for the purpose of killing or taking game, except within the limits included in his appointment as gamekeeper; but that in any case where such gamekeeper shall kill or take any game, or use any dog, gun, net, or other engine or instrument, for the purpose of killing or taking game, beyond such limits, he may be proceeded against as if he had no game certificate whatsoever. Then follow certain clauses which determine the rights of landlords in relation to the game. The act declares, that in all cases where any person shall occupy any land under any lease or agreement made previously to the passing of the act, the lessor or landlord shall have the right of entering upon such land, or of authorizing any other person or persons who shall have obtained an annual game certificate to enter upon such land, for the purpose of killing or taking the game thereon; and no person occupying any land, under any lease or agreement, either for life or for years, made previously to the passing of this act, shall have the right to kill or take the game on such land, except where the right of killing the game has been expressly allowed to such person by the lease or agreement, or except where, upon the original granting or removal of the same, a fine shall have been taken, or except where, in the case of a term for years, the lease or agreement shall have been made for a term exceeding twenty-one years; provided always that nothing contained in the act shall authorize any person seised or possessed of land to kill or take the game, or to permit any other to do so, where, by any deed, grant, lease, or any written or parole demise or contract, a right of entry on such land for the purpose of killing or taking the game has been or shall be reserved or retrieved by, or given or allowed to, the granter or other person whatsoever; nor shall the act affect any reservation or agreement already made in relation to game, nor in any manner prejudice the rights of manor, forest, chase, or warren, nor any of his majesty's forest rights, nor the rights of any grantee of the crown; nor shall the act be deemed to give to any owner of cattlegates, or rights of common, upon or over any wastes or commons, any interest or privilege which he had not before, nor authorize him to pursue or kill the game found on such wastes or commons, nor defeat or diminish the rights and privileges of any lord, or of any steward of the crown, of any manor, lordship, or royalty, in or over such wastes or commons; but that the lord or steward of the crown, of any manor, &c. shall have the right to pursue and kill the game upon the wastes or commons therein, and to authorize any other person who shall have obtained an annual game certificate to enter upon such wastes or commons for the purpose of pursuing and killing game thereon. And it is further enacted, that where the lessor or landlord shall have reserved to himself the right of killing the game upon any land, it shall be lawful for him to authorize any other person who shall have obtained an annual game certificate, to enter upon such land for the purpose of pursuing and killing game thereon; and also, that where the right of killing game is by the act given to any lessor or landlord, in exclusion of the right of the occupier of the land, or where such exclusive right has been or shall be specially reserved by or granted to, or does or shall belong to, the lessor, landlord, or any person whatsoever, other than the occupier of such land, then and in every such case the occupier, if he shall pursue, kill, or take any game upon the land, or give permission to any other person so to do, without the authority of the lessor, landlord, or other person having the right of killing the game, shall on conviction forfeit and pay for such pursuit, such a sum of money, not exceeding L.2, and for every head of game so killed or taken, such a sum of money, not exceeding L.1, as the justices shall be pleased to award, together with the costs of conviction. Then follow certain provisions allowing lords of manors and stewards of the crown-manors to appoint one or more gamekeepers to preserve or kill the game, and with power to seize dogs, guns, nets, and other engines and instruments used within the limits by uncertificated persons, and also allowing lords of manors and stewards of crown-manors to grant deputations to persons as gamekeepers; and, after particular regulations respecting appointments of gamekeepers in Wales, the act declares that no appointment or deputation of a gamekeeper shall be valid, unless registered with the clerk of the peace.

These provisions are followed by a series of important clauses in regard to the *possession, purchase, and sale* of game. The act declares, that every person who shall have obtained an annual game certificate, shall have power to sell game to any person *licensed* to deal in game, provided always that no game certificate on which a less duty than L.3. 13s. 6d. is chargeable, shall authorize any gamekeeper to sell game, except on the account and with the written authority of the master whose gamekeeper he is; and the act appoints special sessions of the peace, to be holden in the month of July yearly, for the purpose of granting licenses to persons therein pointed out to deal in game; and every person so licensed shall annually, and during the continuance of his license, and before he shall be empowered to deal in game under his license, take out a certificate, with a duty of L.2, to be paid to the collector of assessed taxes for the district, under a penalty of L.20. And further, the act declares, that if any person licensed to deal in game shall, during the period of license, be convicted of any offence whatever against the act, his license shall thereupon become null and void. Other clauses which follow create penalties for *killing or taking game*, or using any dog, gun, or other engine, for the purpose of searching for or killing or taking game without a game certificate; for *destroying or taking the eggs* of any bird of game, or of any swan, wild duck, teal, or widgeon, without having right to kill the game, or permission from the person having such right; for *selling or offering to sale* any game, without a game certificate or license, or to unlicensed persons, excepting always innkeepers or tavern-keepers, who, without license to deal in game, may sell game for consumption in their own houses, such game having been procured from some person licensed to deal in game; for *buying game* without a license from unlicensed persons; lastly, on licensed dealers for buying game from uncertificated or unlicensed persons, or for not having up a sign-board, and on unlicensed persons assuming or pretending to be licensed; and the whole is closed by a proviso as to the purchase and sale of game by the *servants* of licensed dealers. Then follows the 30th section, with this preamble: “ And whereas, after the commencement of this act, game will become an article which may be legally bought and sold, and it is therefore just and reasonable to provide some more summary means than now by law exist for protecting the same from trespassers;” whereupon various regulations are made respecting *trespass* in search or pursuit of game. These, however, we shall hereafter specify, because they are substantially the same with those contained in an act since passed for Scotland, to which kingdom the unrepealed act 9 Geo. IV. c. 69, also extends.

In this country there was originally, as in England, no restraint on the taking of game within one's own land. It is particularly noticed, that in the time of King Alexander it was not defended nor forbidden to any man to hunt nor to chase the hare and fox, and other wild beasts, without forests and warrens, wheresoever they were found (M. T. C. c. 52); and as late as the time of King James III. an act was passed (1474, c. 60), declaring that it should not be lawful to hunt or destroy game “ in *utheris* closes or parkes,” without the owner's leave. In the following century the idea of game as the subject of gentlemen's pastime appears; and the act 1551, c. 9, was passed, to restrain certain modes of detroying birds then commonly practised, “ quhairthrow the noblemen of the realme can get na pastime of halking and hunting, like as hes beene had in times bypast.” In the beginning of the seventeenth century the principle of the first English qualification act (13 Rich. II. c. 13), the title of which is, “ None shall hunt but they who have a sufficient living,” was adopted by the Scottish legislature in the act 1600, c. 23; and upon that principle, no doubt, soon followed the statute 1621, c. 31, which enacts “ that no man hunt or hawk at any time hereafter, who hath not a plough of land in heritage, under the pain of L.100 Scots, half to the king and half to the prosecutor.” This is the substantive *Game Qualification Act* of Scotland; and under it the courts have held, that a qualified person may communicate the right of shooting to any individual over the lands of the former; and that a qualified landlord may hunt on his ground in the hands of tenants, paying damage; but that neither a servitude of pasturage nor a lease of land carry a right to kill game, nor yet a lease of game, as against singular successors; nor can a qualified person hunt on the property of another without the owner's leave.

To the qualification required by the act 1621 has been added, by subsequent statutes, that of a *game certificate*, as in England. To make the privilege valuable, various penalties have also been enacted against *poachers;* and lately the act of 9 Geo. IV. c. 69, was passed, applicable to both England and Scotland, to prevent persons *going armed by night* for the destruction of game and rabbits. To all these is now to be added the act above alluded to, namely, 2 and 3 Gul. IV. c. 68, which, though limited to Scotland, is, as already mentioned, nearly a transcript of the 30th and following sections of the late English game act. It enacts and declares, that if any person shall commit any trespass, by entering or being in the daytime upon any land without leave of the proprietor, in search or pursuit of game, or of deer, roe, woodcocks, snipes, quails, landrails, wild ducks, or conies, such person shall forfeit and pay a penalty not exceeding L.2, which is enlarged in the case of the trespass being by a person having his face blackened, coloured, or disfigured, for the purpose of disguise, or by persons to the number of five or more together; and it further declares, that such trespassers may be required to quit the land, and give their names and abodes, and, on their refusal so to do, may be arrested. But it is provided, that the act shall not extend against persons hunting or coursing with hounds or greyhounds, and being in fresh pursuit of any deer, hare, or fox already started upon any other land on which such persons were entitled to hunt or course. The act also declares, that game may be taken from trespassers not delivering the same up when lawfully demanded; and it provides a summary means for ensuring the conviction and punishment of offenders; declaring also, that all penalties created by the statute shall go to the poor of the parish. (U. U. U.)

GAMELIA, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before a marriage. It was so called from a custom they had of shaving themselves on this occasion, and presenting their hair to some deity to whom they had particular obligations.

GAMELION, in the ancient chronology, was the eighth month of the Athenian year, containing twenty-nine days, and answering to the latter part of our January and beginning of February. It was so called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

GAMING, the art of playing or practising any game, particularly those of hazard, as cards, dice, tables, and so forth.

Gaming was particularly remarked by Tacitus as distinguishing the ancient Germans. “ They addict themselves,” says he, in his treatise *De Moribus Germ.* c. 24, “ to dice, as a serious employment, with such an extravagant desire to win or lose, that when everything else fails they will stake even their liberty and their very persons. The loser goes into a voluntary servitude: though younger and stronger than his antagonist, he suffers himself to be bound and sold; and this perseverance in so bad a cause they call the point of honour.” This passion we seem to have inherited; and by the ancient common law of the land it was not forbidden. Its pernicious consequences, however, are manifest; and both the legislature and the courts have interfered to restrain it.

In England there are three principal statutes on the subject, and a multitude of minor ones, the particular descriptions and prohibitions of the law being ever behind the inventions of sharpers and interested men. The first statute, 33 Hen. VIII. c. 9, was directed against the inferior classes, and prohibits to all but gentlemen the games of tennis, tables, cards, dice, bowls, and other unlawful diversions therein specified, unless in the time of Christmas, under pecuniary pains and imprisonment. But this was legislation at once unequal, cruel, and impolitic, and indeed, according to modern experience at least, it is gaming in high life which particularly requires to be restrained. Accordingly, by 16 Car. II. c. 7, it was enacted that if any person shall play at any of the games mentioned in the second section, namely, cards, dice-tables, tennis, bowls, skittles, shovel-board, or cock-fighting, horse-races, dog-matches, foot-races, or other pastimes or games whatsoever, or shall bet on the side or hands of such as play thereat, and shall lose any sum or sums of money or other thing exceeding L.100, at any time or meeting upon ticket, credit, or otherwise, and shall not pay down the same at the time of the loss, the value shall not be recovered; but all contracts for the same, judgments, statutes, recognisances, mortgages, &c. and all other acts, deeds, and securities for the same, shall be void, and the winner shall forfeit treble the value, in addition to the sum of L.100, half thereof to the king and half to the informer. At length came the gaming act (9 Anne, c. 14), which declares that all bonds and other securities given for money won at play, or money lent at the time to play withal, shall be utterly void; that all mortgages and incumbrances of lands made upon the same consideration shall be and revert to the use of the heir of the mortgager; that if any person at any time or sitting loses L.10 at play, he may sue the winner, and recover it back by action of debt at law; and in case the loser does not, any other person may sue the winner for treble the sum so lost; and the plaintiff may by bill of equity examine the defendant himself on oath. Moreover, if any person, by cheating at play, shall win any money or valuable thing, or shall at any time or sitting win more than L.10, he may be indicted thereon, and shall forfeit five times the value to any person who will sue for it, and shall be deemed infamous, and suffer such corporal punishment as in the case of wilful perjury. And this statute of 9 Anne is further enforced, and some deficiencies supplied, by 18 Geo. II. c. 34.

By the first of the above-named acts also (33 Hen. VIII. c. 9), to which may now be added 58 Geo. III. c. 70, and 3 Geo. IV. c. 114, the keeping a *gaming-house* was declared a nuisance, which indeed it is held to be, and an indictable offence at common law; and the courts largely construing the word, have held a cockpit a gaming-house within the meaning of the statute (3 Keb. 510, 2 Burr. 1233). By 9 and 10 Will. III. c. 17, all *lotteries* were declared public nuisances; and all state-lotteries which had in the interval been allowed were to be discontinued after 4 Geo. IV. c. 60. As to private lotteries, they were prohibited by various statutes of the reign of George II. under heavy pecuniary penalties. In the same reign, to prevent or restrain *horse-racing*, another kind of gaming, it was enacted by 13 Geo. II. c. 19, that no plate or match under L.50 value shall be run, under a penalty of L.200 to be paid by the owner of each horse running, and L.100 by such as advertise the plate, except at Newmarket and Black Hambleton, where a race may be run for a less sum than L.50: but though such horse-races are lawful, yet they are construed *games* within 9 Anne c. 14, and consequently wagers above L.10 are illegal. By 7 Geo. II. wagers relating to the present or future price of stocks are declared illegal and void; and it has been held that a wager between two electors upon the success of their respective parliamentary candidates is illegal, because it tends to corrupt the freedom of election (1 T. R. 56). The law of *wagers* is well and succinctly traced by Mr Christian in his note to 4 Blackstone, 173. Wagers, in general, says he, were by the common law lawful contracts; and all wagers may still be recovered in a court of justice which are not made upon unlawful games, or which are not such as are likely to disturb the public peace, or to encourage immorality, or such as will probably affect the interests, characters, and feelings of persons not parties to the wager, or such as are contrary to sound policy or the general interests of the community. And the recent editor of Blackstone subjoins to this note a case lately decided, to show the comprehensive ground on which one of these doctrines, that of public policy, rests. The case was this. In 1802 the defendant, in consideration of 100 guineas, agreed to pay the plaintiff one guinea a day during the life of Bonaparte. The defendant paid the money for some years, and then stopped. The action was brought to recover the arrears. The jury having found for the defendant, on a motion for a new trial it was contended in support of the verdict that the wager was illegal, inasmuch as it had a tendency to create an interest in the plaintiff in the life of a foreign enemy, and which in the case of an invasion might induce him to act contrary to his allegiance. The court being of opinion that the justice of the case had been satisfied, refused to disturb the verdict; and Lord Ellenborough, chief-justice, expressed a strong opinion against the legality of the wager, as well on the ground before mentioned, as also on the ground that the party suffering under such a contract might be induced to compass and encourage the horrid practice of assassination, in order to get rid of a life so burdensome to him (16 East. 150). So likewise, where a person had given L.100 on condition of receiving L.300 if peace were not concluded with France within a certain time, and he afterwards brought his action to recover the L.300, it was held that the wager was void, as being inconsistent with general policy; but he was allowed to recover the L.100 which he had paid, under a count for so much money received by the defendant to his use. Indeed we may remark frequent expressions of regret by the most eminent judges of England, that the law of wagers in that country is not the same with that of Scotland; and some, amongst whom was Justice Butler (3 T. R. 697), have thought it was not too late yet to retrace their steps, and to adopt the practice of the Scotch courts. So in Easter term 1825, Chief-Justice Abbot refused to allow a cause to proceed in which a person sought to recover L.100 which had been deposited as a stake on a dog-fight, observing that all such wagers were illegal. In like manner, the chief-justice discharged the jury from giving any verdict in an action to recover a deposit on a wrestling match (Kennedy, K. B. October 29, 1828).

The view taken in Scotland is, that courts of justice were instituted to redress wrong in the serious transactions of life; and that wagers and gaming debts do not partake of the character of serious business, but mere pastime and amusement. The judges therefore look upon such contracts as *sponsiones ludicræ*, and will not allow action for the recovery of sums lost or won by wagering or betting in any form; and this is now settled law, and sanctioned by the judgment of the House of Lords in the case of Bruce *v.* Ross, 14th February 1788. Where, however, a civil injury arises, though it be out of gaming, the party will be heard. So, in the case of Paterson, 1830 (8 Sh. and D. 573), a party brought an action setting forth that he had fairly won money at cards from the defender, who paid it, but afterwards demanded restitution, alleging the pursuer was a cheat at play; and that the pursuer thereupon repaid the money on condition that the defender should preserve silence on the subject, which he failed to do; and the defender offered to prove the pursuer a cheat. The court found the action relevant, and remitted it to the jury court, where it was tried as a question of defamation.

Scotland is also distinguished from England by the paucity of its legislative provisions on gaming. By 1621, c. 14, it was enacted that none play at cards or dice in any common house, town, hostelrie, or cook's house, and that it should not be lawful to play in any other private man's house but where the master of the family playeth himself; and if it should happen any man to win a sum exceeding 100 merks within the space of twenty-four hours, or to gain at wagers upon horse-races any sum above 100 merks, the surplus should go to the poor of the parish. This act is not altogether in desuetude, as might be thought from an old case, but it is available only to the poor, and not to the winner (Straiton, 19th July 1688; Maxwell, 14th July 1774). To the above act of 1621 are to be added the acts 9 Anne and 18 Geo. II. above noticed, which are received in Scotland, but have not always the same construction given them as in England. Thus, as remarked by Mr Brodie (Stair, b. i. tit. 10, sect. 8, note), it has been held in Nelson *v.* Bruce, Mor. 9507, and Stewart *v.* Hyslop, Mor. 9510, contrary to the settled construction in England, that the nullity was not effectual against an onerous indorsee not aware of the bill being granted for a game debt. Mr Brodie gives it as his opinion that the two Scottish decisions are on principle, abstractedly from the words of the statute, most consonant to substantial justice; but the English construction appears quite indisputable. (U. U. U.)

Chance, or *Hazard*, in GAMING. Hazard, or chance, is a matter of mathematical consideration, because it admits of more and less. Gamesters either set out upon an equality of chance, or are supposed to do so. This equality may be altered in the course of the game, by the greater good fortune or address of one of the gamesters, by which he comes to have a better chance, so that his share in the stakes is proportionably better than at first. This more and less runs through all the ratios between equality and infinite difference, or from an infinitely small difference till it come to be an infinitely great one, by which the game is determined. The whole game, therefore, with regard to the issue of it, is a chance of the proportion which the two shares bear to each other.

The probability of an event is greater or less, according to the number of chances by which it may happen, compared with the number of all the chances by which it may either happen or fail. See PROBABILITIES.

GAMMONING, among seamen, denotes several turns of a rope taken round the boltsprit, and reeved through holes in knees of the head, for the greater security of the boltsprit.

GAMUT, *Gam-ut*, in *Music*, a scale on which the musical notes, *ut*, *re*, *mi*, *fa*, *sol*, *la*, are sounded in their several orders and dispositions. See MUSIC.

GANDICOTTA, or WANDICOTTA, a district of Hindustan, in the Balaghaut ceded districts, situated between the fourteenth and fifteenth degrees of north latitude, and now chiefly comprehended in the Cuddapah collectorship. The river Pennar crosses it. The principal towns are Gandicotta, Tadimery, and Anantapooram. Gandicotta is the capital of the district, situated on the top of a lofty mountain. There is no passage to the fortress but by a narrow road cut out of the rock along the edge of the precipice. The surrounding plain is well watered and cultivated; and here was formerly a diamond mine. Long. 78. 20. E. Lat. 14. 44. N.

GANGES. This great river has its rise in the northern face of the Himalaya Mountains, and, after a course of about two thousand miles, falls into the Bay of Bengal through numerous channels. The remote sources of the Ganges were long imperfectly known, and afforded a fertile subject of conjecture and controversy to the geographers of Europe. Prior to the commencement of the nineteenth century, this river had been traced by Hindoo pilgrims to Gangoutri, the point at which it issues from the Himalaya Mountains; but all accounts agreed that its origin was still more remote. On the side of Thibet it had been surveyed by lamas or priests, sent for that purpose by the Emperor Camhi, whose route terminated at Kentaisse, a range of snowy mountains on the west and south of Thibet. The most general notion was, that it flowed within the Himalaya chain of snowy mountains for many hundred miles, from the imaginary lake of Mapama, to Gangoutri. In 1808, Lieutenant Webb was sent by the Bengal government to explore the sources of the Ganges. About seventeen miles beyond Gangoutri his further progress was stopt by the difficulties of the country, but the Moonshee who accompanied the party went forward; and as he proceeded upwards, after leaving Gangoutri, he occasionally perceived the river among the snow, which a little higher up so completely filled its bed that no trace of it could be discovered. Five hundred yards further on it again showed itself; but in front was a steep mountain, rising up like a huge wall, from an angle of which the Ganges appeared to issue, whilst all beyond was an impenetrable mass of snow. This is the furthest point to which the Ganges has been traced, and may be considered as its source; though others think the Dauli to be the main stream, owing to the length of its course from Gangoutri. Two miles higher up the river is the place called the Cow's Mouth. It is a large stone in the middle of the river, the water passing it on each side, and leaving only a small piece above the surface, to which the fancy of superstition has given the form of a cow's head, an animal held sacred by the Hindoos. From Gangoutri the Ganges flows, in the upper part of its course among the mountains, from south-east to north-west; and it is only from Sookie, where it fairly pierces through the Himalaya range, that it assumes a course south-west to Hurdwar. Here, in the latitude of 30° N. it gushes through an opening in the mountains, and flows with a smooth navigable stream to its conflux with the Jumna at Allahabad, the first large river that joins it in Hindustan proper. Its bed is of very unequal breadth. From its first arrival in the plains at Hurdwar to the conflux of the Jumna, it is generally from a mile to a mile and a quarter wide, and, compared with the latter part of its course, tolerably straight. From hence downward it becomes more winding; till, having successively received the waters of the Goggrah, the Soane, and Gunduck, besides numerous smaller streams, its bed has attained its full width, which varies from half a mile to three miles. The stream is always increasing or decreasing, according to the season; and in April, when it is lowest, the principal channel varies from four hundred yards to about a mile and a quarter. At the height of the inundation the breadth of the river is of course greater; and Bishop Heber mentions, that at Boglipoor, about six hundred miles from the sea, including the turnings of the river, the breadth was nine measured miles across. Though the Ganges be fordable in some places above the conflux of the Jumna, the navigation is never interrupted. Below, the depth of the channel is increased, the additional streams bringing a greater accession of depth than breadth. At five hundred miles from the sea, the channel is thirty feet deep when the river is lowest, and it continues at least this depth to the sea, when the sudden expansion of the stream deprives it of the force necessary to sweep away the bars of sand and mud thrown across it by strong southerly winds; so that the principal branch of the Ganges cannot be entered by large vessels. At about two hundred and twenty miles from the sea, or three hundred reckoning the windings of the river, commences the head of the Delta of the Ganges. The two easternmost branches, named Cossimbazar and Jellinghy rivers, unite and form what is afterwards denominated the Hooghly, which is the port of Calcutta, and the only branch of the Ganges that is commonly navigated by ships. Below the channel named the Songti Mohana, where the Ganges sends off these two branches which go to Calcutta, the main stream loses not only its name, but the greater part of its sanctity in the eyes of the natives. The Cossimbazar river is almost dry from October to May, nor is the Jellinghy river navigable during two or three of the driest months; so that the only subordinate branch of the Ganges which is at all times navigable is the Chandnah river, which separates at Moddapoor, and terminates in the Hooringotta river. That part of the Delta called the Sunderbunds consists of a labyrinth of rivers and creeks, which is two hundred miles broad at the junction of the Ganges with the sea. This tract is covered with woods which are infested with tigers, and its numerous canals form a complete inland navigation across the lower part of the Delta. The Ganges, like all tropical rivers, overflows periodically during the season of the rains in Bengal, on which it depends for its supplies, and not, as may be supposed, on the melting of the mountain snows. Its rise is thirty-two feet, fifteen and a half of which it rises by the latter end of June, and it is not until this time that the rainy season commences in the plains. By the end of April, when the rains from the mountains have reached Bengal, the rivers begin to rise at the rate of an inch per day for the first fortnight, which augments to two and three inches before any quantity of rain has fallen; and when the rain becomes general, the river increases, at a medium, to five inches per day. By the latter end of July all the lower parts of Bengal are inundated. The inundation is at a stand in the middle of August; and it gradually and slowly decreases in August and September, and until April, when it again begins to rise. The quantity of water discharged is calculated in the dry season to amount to 80,000 cubic feet per second, and during the inundation to 405,000 cubic feet. The descent of the river is about nine inches per mile, and estimating the windings of the stream, four inches per mile. In the dry season the current is three miles an hour; it increases during the wet season to five or six miles, and in particular situations to seven or eight miles. On the banks of the Ganges, where the soil is loose, and the current rapid, "such tracts of land," says Major Rennell, "are swept away in one season as would astonish those who have not been eye-witnesses to the magnitude and force of the mighty streams occasioned by the periodical rains of the tropical regions." Great changes are in this manner produced in the course of the river, what is lost on one side being gained on the other by the mere operation of the stream. In its course through the plains the Ganges receives eleven rivers, some of which are larger than the Rhine, besides many others of less importance. The Goggrah, the Soane, and the Coosy, are the largest of the tributary streams in Bengal and Bahar. The Brahmapootra has its rise near the source of the Ganges, and from hence the two rivers diverge widely asunder; but afterwards they intermix their waters before they fall into the sea, the Ganges having then performed a course, including its windings, of about 1500 miles.

GANGOUTRI, a celebrated place of Hindoo pilgrimage, situated among the Himalaya Mountains, in the province of Serinagur, on the Ganges, which is here not above fifteen or twenty yards broad, with a moderate current, and not in general above three feet deep. The course of the river is here north by east; and on the bank near Gangoutri there is a small temple about eight or ten feet high, in which are two images representing the Ganges and Bhagirathi rivers. The bed of the river adjoining the temple is divided off by the Brahmins into three basins, where the pilgrims bathe. One of these portions is dedicated to Brahma, the other to Vishnu, and the third to Seva. The pilgrimage to Gangoutri is considered as a great achievement of Hindoo piety, and efficacious in washing away all the previous sins of the devotee, and ensuring him eternal happiness in the world to come. The water taken from this sacred spot is exported by pilgrims to India, and sold at a high price; it is drawn under the inspection of a Brahmin, to whom a trifling sum is paid for the privilege of taking it; and the vessels are then sealed. In 1808 Lieutenant Webb and his party approached within sixteen or eighteen miles distance of this consecrated spot. The pilgrims report that the current of the Ganges, only a few miles from this place, issues from under a bed of perpetual snow, where the roads are so bad, that few persons have been able to penetrate to the spot. Long. 78. 9. E. Lat. 31. 4. N.

GANGPOUR, a small district of Hindustan, in the province of Gundwana, situated about the twenty-second degree of north latitude, and bounded on the north by the British district of Chuta Nagpoor, in Bahar. It was annexed to the province of Allahabad during the reign of Aurungzebe, though it was only reduced under nominal subjection to that monarch. It is a barren, mountainous, and unproductive country, still inhabited by uncivilized tribes of Hindoos. The chief river is the Soank, and the principal towns are Gangpoor and Padah.

GAN-KING-FOO, a large city of China, situated on the great river Yang-tse-kiang, and capital of the province of Kiang-nan. It is a place of considerable trade. Great part of the space within the walls consists of gardens and cultivated ground. The eastern quarter is composed chiefly of dwelling-houses, and the western of shops, which are well furnished, particularly with porcelain, horn lanterns, caps, drapers' and mercers' goods, &c. Long. 117. 20. E. Lat. 31. 30. N.

GANJAM, a town and sea-port of Hindustan, in the Northern Circars, and capital of a district of the same name. It is situated on the north-eastern bank of a river, which is only navigable during the rainy season, when a great part of the surrounding country is inundated. It possesses a fort, which is a regular pentagon on plain ground, well fortified, and capable, when properly garrisoned, of making a respectable defence. Ganjam is one of the five districts into which the Northern Circars have been subdivided, and is the residence of a judge and collector. This port is much frequented by country vessels; and formerly the East India Company were provided with a large investment from it. But since the great improvements which have taken place in the cotton manufactures in England, the demand for India cotton goods has greatly decreased, and the establishment now scarcely pays its expenses. Long. 85. 19. E. Lat. 19. 23. N. The district of Ganjam is in Cicacole, and one of the Northern Circars.

GANTLET, or GAUNTLET, a large kind of glove made of iron, and having the fingers covered with small plates. It was formerly worn by the cavaliers, when armed at all points. The word is derived from the French *gantelet;* and that from *gand* or *gant*, a glove. The casque and gauntlets were always borne in the ancient marches of ceremony. Gauntlets were not introduced until about the thirteenth century. The gauntlet was frequently thrown, like the glove, by way of challenge.

GANYMEDE, in *Mythology*, a beautiful youth of Phrygia, son of Tros, and brother of Ilus; but, according to Lucian, he was the son of Dardanus. Jupiter having been charmed with him, carried him away, and made him his cup-bearer in the room of Hebe. Some say that the chief of the gods caused him to be carried away by an eagle, whilst others affirm that he was himself the ravisher under the form of that bird. He deified this youth; and, to comfort his father, presented him with some of those very swift horses upon which the gods indulged in equitation.

GAOL (*Gaola*, Fr. *Géole*, that is, *Caveola*, a cage for birds) is used metaphorically for a prison. See PRISONS.

GAOL *Delivery.* The administration of justice being originally vested in the crown, our kings in former times rode in person through the realm once in seven years, to judge of and determine crimes and offences; but afterwards justices in eyre were appointed, and since that time justices of assize and gaol delivery. A commission of gaol delivery is a patent in the nature of a letter from the king to certain persons, appointing them his justices, or two or three of them, and authorizing them to deliver his gaol, at such a place, of the prisoners in it; for which purpose it commands them to meet at such a place, at such time as they themselves shall appoint; and informs them, that for the same purpose the king has commanded his sheriff of the same county to bring all the prisoners of the gaol, and their attachments, before them at the day appointed.

GAONS, a certain order of Jewish doctors who appeared in the East after the closing of the Talmud. The word *gaons* signifies excellent or sublime; as in the divinity schools we formerly had irrefragable, sublime, resolute, angelic, and subtile doctors. The Gaons succeeded the Seburæans, about the beginning of the sixth century. Chanan Meischtia was the head of the excellents, and restored the academy of Pandebita, which had been shut up for thirty years.

GAP, an arrondissement of the department of the Upper Alps, in France, extending over 445 square miles. It is divided into fourteen cantons and 122 communes, and inhabited by 63,825 persons. The capital, a city of the same name, is situated on the river Luie, on a kind of basin formed by hills, over which tower the snow-covered mountains of the Alps. It is an old and ill-built place, containing 8150 inhabitants, who are occupied in making linen and woollen cloths. There is in the city a museum, containing collections of the plants, minerals, birds, and antiquities of the Alps. Long. 5. 59. 42. E. Lat. 44. 33. 37. N.

GARAMOND, Claude, an ingenious letter-founder, was born at Paris, where he began, in the year 1510, to found printing types free from all the remains of the Gothic, or, as it is generally called, the black letter, and brought them to such perfection that he had the glory of surpassing all who went before him, and of being scarcely excelled by any of his successors in that useful art. His types were prodigiously multiplied, both by the great number of matrices he struck, and the types formed in resemblance of his in all parts of Europe. Thus in Italy, Germany, England, and Holland, the booksellers, by way of recommending their books, distinguished the type by his name; and, in particular, the small Roman was by way of excellence known amongst the printers of these nations by the name of *Garamond's small Roman.* By the special command of Francis I. he founded three sizes of Greek types for the use of Robert Stephens, who by means of them printed all his beautiful editions of the New Testament, and other Greek authors. He died at Paris in 1561.

GARASSE, Francis, a remarkable writer, and also the author of that irreconcilable enmity which still subsists between the Jesuits and Jansenists, was born at Angoulême in 1585, and entered the Jesuits' College in 1600. As he had a quick imagination, a strong voice, and a peculiar turn for wit, he became a popular preacher in the chief cities of France; but not content with this honour, he distinguished himself still more by his writings, which were bold, licentious, and produced much controversy. The most considerable in its consequences was entitled *La Somme Théologique des Veritez capitales de la Religion Chrêtienne,* which was first attacked by the abbot of St Cyran, who observing in it a prodigious number of falsifications of the Scriptures and of the fathers, besides many heretical and impious opinions, conceived that the honour of the church required him to undertake a refutation of it. Accordingly he published an answer, whilst Garasse's book was also under examination of the doctors of the Sorbonne, by whom it was afterwards condemned. Garasse replied to St Cyran; but the two parties of Jesuits and Jansenists, of whom these were respectively the champions, gradually conceived such an implacable animosity against each other, that it is not even now likely to subside. The Jesuits were forced to remove their brother to a distance from Paris, where, weary of his inactive obscurity, he begged leave of his superior to attend the sick, when the plague raged at Poitiers in 1631, and in this charitable office he caught the prevailing distemper, and died.

GARAWAL, a town of Hindustan, in the province of Allahabad, and district of Chunar. It is the last town of any consequence on the frontier between the British provinces and those of the rajah of Berar. Long. 83. E. Lat. 24. 50. N.

GARBE, in *Heraldry,* a sheaf of any kind of grain, borne in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

Garcias-Laso.

GARCIAS-LASO, or Garcilaso, or Garcilasso de la Vega, a celebrated Spanish poet, was born at Toledo, in 1503. He was the younger son of Garcilaso, counsellor of state to Ferdinand and Isabella, their ambassador at the court of Rome, and grand commander of Leon, and of Sanchette de Guzman, lady of Batres, a considerable property of the illustrious house of Guzman, where may yet be seen a fountain which has existed for several centuries, and still bears the name of Garcilaso. Ferdinand V. conferred on the father of Garcilaso the name of Vega, in memory of a single combat which the former maintained against one of the most valiant of the Moors on the Vega, or plain of Grenada; and which was celebrated in the Spanish romances and histories of that age. Garcilaso was intended by nature for a rural and solitary life, at least if a judgment may be formed from his poetical productions, which all breathe nothing but love and peace, and manifest extreme gentleness of character. But his birth having called him to the profession of arms, his life was passed in camps, and his career was brilliant and tumultuous. He entered early into the army of Charles V., followed that monarch in the war of the Milanese (1521), and, though still young, distinguished himself by his valour, particularly at the battle of Pavia. In 1523 he served in the Spanish corps, which, having joined the imperial army, distinguished itself by its bravery against the Turks. In acknowledgment of his courage, Charles V. conferred on him, at Vienna, the cross of the order of St James. Garcilaso, by his merit, established himself in the good graces of the emperor; but a gallant adventure for ever deprived him of the favour which his talents and bravery had won. One of his cousins having become enamoured of a lady of the court, who, it seems, had gained the affections of Charles, Garcilaso favoured by all means in his power the passion of his relation, whose intentions were honourable. When the fact became known to the emperor, he sent the cousin into exile, and banished Garcilaso to an island in the Danube. During his detention, which was not of long duration, the latter composed one of his *Canciones,* in which he deplores his misfortune, and at the same time celebrates the charms of the country watered by the divine stream of the Danube (*Danubio rio divino*). In 1535, he served in the expedition which Charles V. undertook against Tunis, whence he brought back nothing but wounds and glory. He then passed some time in Naples and in Sicily, where he indulged in his favourite occupation of poetry. Pouring out maledictions on war, as the bane of nations and the destroyer of human happiness, he pleased himself with creating an imaginary romantic Arcadia, free from all the passions, tumults, and anxieties which distract men in this every-day common-place world; but notwithstanding these benign and peaceful pictures painted by his fancy, he still remained the soldier, and, in addition to his acknowledged courage, evinced considerable military talents. Hence, in 1536, he marched with the imperial army into France, having under his orders thirty companies of Spanish troops. But this was the last campaign of Garcilaso, who, in the disastrous retreat from Marseilles, found a death worthy of his valour. A number of French peasants having occupied a tower, whence they greatly annoyed the imperial army on its retreat, the emperor ordered Garcilaso to carry it by assault. He obeyed, but executing his order with less prudence than valour, he mounted the first to the assault, and was overthrown by a mass of stone, which struck him on the head, and inflicted a mortal wound. He was conveyed in this state to Nice, where, after lingering twenty hours in great agony, he expired in November 1536, being then in the thirty-third year of his age. Arms and letters sincerely deplored his loss; and the emperor himself was so touched, that when the tower had been carried, he caused twenty-eight peasants who remained out of the fifty who formed its garrison to be hanged on the spot where the poet-soldier had fallen. At the age of twenty-eight Garcilaso had married an Aragonese lady, Doña Helena de Zuñiga, by whom he had a son, who, like his father, fell in the flower of his age (1569), in a combat with the Dutch.

Although the military career of Garcilaso is not without glory, yet he owes his reputation to his literary merit, more especially to the reformation he effected in Spanish poetry, and which forms an epoch in the age in which he lived. For several centuries before the birth of Garcilaso, the Spaniards possessed a species of poetry.[1] The first known compositions were romances, produced probably in the mountains of Asturias; and the first people amongst whom a less rude and incorrect kind of poetry appeared, were the Valencians and the Catalans, who wrote in their own particular language. The last of these troubadours was Jago Roig, who died at the commencement of the fifteenth century.[2] In the kingdoms of Leon and Aragon, where the Castillian dialect prevailed, the only poetical compositions at first known were these romances, composed of *redondillas* or *assonantes*,[3] each verse being subjected to a measure consisting of four trochees. Much about the same time appeared the verses of the *Arte Mayor*, composed of twelve syllables, like the following, in which Alfonso the Wise relates that he had learned from a celebrated alchemist how to make the philosopher's stone, by means of which he had been enabled to augment his revenues:

> La piedra que llaman philosophicàl.
> Sabia fazer, e mi la ensennò. .
> Fizimos la juntos, despues solo yò. .
> Con que muchas veces cresciò mi caudàl.

In the same century, that is, about the middle of the thirteenth, a Benedictine named Barceo introduced the verses called Martelliani by the Italians, and Alexandrine by the French:

> Quiero far una prosa en roman paladino
> En el qual suele el pueblo hablar a su vecino.

But this metre has for a long time fallen into almost total disuse, except in Spain. In fact, it was only under the reign of John II. a great protector of letters, who swayed the sceptre from 1401 to 1454, that Spanish poetry assumed a character truly national. This prince collected around him the ablest Valentian troubadours, and the most renowned Castillian poets; and it was then that the learned Marquis of Villenas, John of Mena, the Marquis Mendoza of Santillane, John of the Encina, and others, appeared, and that versification was subjected to some rules, conformably to the precepts laid down in *Arts of Poetry* composed by the two authors last named. But this versification was still very rude, when Dante, Petrarch, and Sannazaro had already made themselves admired in Italy and in all Europe, by the excellence and beauty of their compositions. At length came Boscan and Garcilaso, who, united from their earliest infancy in the closest friendship, and alike sensible of the merit of the three great Italian poets, the perusal of whose works had formed at once their taste and their understanding, resolved to effect a general reform in the bad taste which still prevailed in their own country. Boscan was the first to enter the field. He introduced the sonnet, the *canzoni*, the *stanze*, and the endecasyllabic measure of the Italians; and his efforts were crowned with success. Garcilaso merely followed Boscan, but, on the other hand, he had the talent to surpass him, and approached more nearly to the sweetness and softness of Petrarch, whilst his rival imitated the precision and energy of Dante. All the contemporary poets united in opposing a reform the success of which would infer their condemnation; but although they evoked the shades of their illustrious predecessors, the genius of the two wise innovators triumphed over their cabals. Garcilaso and Boscan obtained the title of Fathers of the Good School; Garcilaso was named the Spanish Petrarch, the Prince of Spanish Poetry; and the desired reform was effected. It was followed by good imitators,[4] till the apparition of Andalous Gongora, who appeared to have undertaken the task of banishing for ever good taste from his country; but, in spite of all his efforts, and those of his partisans, under the reign of Charles V. and the three Philips, his successors, Spain was fertile in good poets; and, in recent times, Iriarte, Cienfuegos, Moratin, Arellano, Quintana, and, above all, Melendez-Valdez, have enabled their countrymen to taste the delights of true poetry. Boscan, who survived Garcilaso six years, collected the works of the latter; but death surprised him before he was enabled to give them to the world. The first known edition is that of Venice, 1553, in 8vo. The celebrated grammarian Sanchez, called in Latin Sanctius, had corrected what he found defective in the oldest edition; but the most esteemed edition is that of Madrid, 1765, in 16to, containing a preface and notes, which prove the anonymous editor to have been an able and enlightened man of letters. It is not by the multitude of his works that Garcilaso has secured immortality, since they are all contained in a small volume; but this volume includes all that is necessary to serve as a model to the best poets of the Spanish nation.

The style peculiar to Garcilaso is the tender and the pathetic, which predominates, in a high degree, in all his compositions. Amongst the sonnets, which are thirty in number, may be particularly distinguished that one which commences,

> O dulces prendas por mi mal halladas;

and also another, not less beautiful, beginning,

> Si quexas y lamentos pueden tanto,

which Sismondi has translated with equal elegance and precision.[5] But the composition which forms the glory of Garcilaso is the first of his three eclogues, which has served as a model to a crowd of imitators, who have not of course succeeded in approaching it. This poem, consisting of about four hundred verses, was written at Naples, where the author seems to have at once imbibed the spirit of Virgil and of Sannazaro. Two shepherds, Salicio and Nemoroso, meet, and, by their plaintive songs, express the grief occasioned to the one by the infidelity,

> Por tì silencio de la selva umbrosa,

and to the other, by the death, of his shepherdess,

> Como al partir del sol la sombra cresce.

In the first, there is a softness, a delicacy, a submission;

---

[1] *Coleccion de Poesias Castellanas anteriores al Siglo* xv. by Don Antonio Sanchez, Madrid, 1782, in 4 vols. 8vo. In this collection are contained the poem of the *Cid*, written towards the middle of the eleventh century; that of *Alexander the Great*, which belongs to the twelfth; the pieces of the archpriest of Fita, who lived at the commencement of the thirteenth; and the poems of Barceo, who died in 1268.

[2] *Los Dones de Roig*, Valentia, 1735, in 4to.

[3] The *redondillas* consist of four verses, in which there is an exact and full rhyme, as *razon*, *corazon*, called *consonante*. The *assonante* is the echo of the final vowel, and not of the final consonant of the verse to which it corresponds, as *sano*, *raso*, *claro*, &c. When the romance is composed of redondillas, these change rhymes successively; but when it is composed of assonants, a single vowel predominates throughout the whole romance.

[4] These imitators, in adopting the Italian metres introduced by Boscan and Garcilaso, have nevertheless preserved their *redondillas*, their *assonantes*, and their *octaves*, which had been known in Spain since the fourteenth century.

[5] *Littérature du Midi de l'Europe*, tome iii. p. 270.

in the second a depth of grief; in both a purity of pastoral sentiment, which strike us the more forcibly when we recollect that the writer was a warrior destined to perish a few months afterwards in leading an assault. Each verse charms at once by the truth of an exalted but touching sentiment, by the happy choice of expression, and by a harmony which never fails to satisfy even the most delicate ear. Nevertheless, the song of Nemoroso is still more fascinating than that of his associate, perhaps, because it moves us more gently. The passage where he speaks of the buckle of his mistress's hair,

> Una parte guarde de tu cabellos,

which he carries on his heart, and with which he is resolved never to part, has no model, neither among the ancients nor among the moderns.[1] Garcilaso has also written elegies, of which one was composed at the foot of Mount Ætna; they are to be found in the same volume. Independently of the rare merit of all his compositions, which have placed the author in the first rank amongst the lyric and bucolic poets of his nation, the single eclogue to which we have just referred would of itself be sufficient to ensure him immortality.

This poet must not be confounded with another person of the same name, but surnamed the Inca, a Spanish historian, born at Cuzco in 1530, who wrote, 1. Part First of Royal Commentaries, treating of the origin of the Incas, their laws, and their government, Lisbon, 1609, in folio; 2. Part Second of the Incas, or General History of Peru, Lisbon, 1617, in fol.; 3. History of Florida by the Inca, Lisbon, 1605, in 4to. (A.)

GARD, a department of the south-east of France, formed in part of the ancient province of Nismes, and of Uzes and Alais, formerly portions of Languedoc. It is bounded on the north by the departments of Lozère and Ardêche, on the east by Vaucluse, on the south-east by the Mouths of the Rhone, on the south by the Mediterranean Sea, on the south-west by Herault, and on the west by Aveiron. It extends over 2314 square miles, containing, according to the royal almanack, 599,723 hectares. It is divided into four arrondissements, thirty-eight cantons, 365 communes, and contains 357,383 individuals, of whom about one third profess the Protestant religion. There is great variety in the face of the country. The southern part, which extends to the sea, and was probably once covered by it, is a level plain, with many morasses, lakes, and dykes. The northern parts are higher, and some of them mountainous. The range of the Cevennes Hills passes through these portions, and from them issue the rivers Allier towards the north, the Lot and the Tarn towards the west, the Hérault and the Bedourle towards the south, and the Ardêche and the Gardon towards the east, abundantly watering the valleys on both sides. The soil is generally either calcareous or schistose, resting on a bed of granite, and better adapted for the growth of olives, grapes, and other fruits, than for corn. The climate, especially to the south, is mild; snow rarely falls, and quickly disappears; but, on the other hand, the summers are excessively hot, and the air arid.

Although some good wheat is grown near Nismes, yet it is insufficient for the few who eat it, and the greater part of the inhabitants are fed with rye, oats, and buck-wheat, and during a great part of the year with chestnuts. This latter, amongst the peasantry, furnishes a meal three times a day, either boiled or fried in olive oil; and when a bad year for them happens, the sufferings of the poor are excessive. The chief products of the department are wine, brandy, and oil; but large quantities of silk are made in some districts. The yearly production at present is calculated to be 150,000 pounds of raw silk; before the Revolution it was 350,000 pounds. The horses and cows have no distinguishing properties, but the sheep are an excellent race, producing good wool, milk that is made into cheese, and very savoury meat. The manufacturing industry is not considerable, consisting of the fabrication of cloth, silks, hats, glass, earthenware, and perfumery.

The trade of the department is confined to the export of wine, brandy, raisins, chestnuts, capers, liquorice, coal, salt, and wool.

GARDA, a beautiful lake in the Austrian dominions in Italy, called by the ancients Benacus. It is situated at the foot of the Tyrolean Alps, and formed by numerous rivulets, chiefly issuing out of the province of Styria. It forms a river at Peschiera, then called by the name of the Mincio. It is about thirty-five miles in length, varying in its breadth, but nowhere more than fourteen miles across. In the centre it is said to be three hundred feet deep. A small town of the same name is situated on the eastern side of the lake, which, in the ancient civil wars, was a port of some importance. On the banks of this lake Bonaparte defeated the Austrians commanded by Wurmser in 1796.

GARDANT, or GUARDANT, in *Heraldry*, denotes any beast full faced, and looking right forward.

GARDELEGEN, a city of the Prussian province of Saxony, the capital of a circle of the same name. It is situated on the river Milde, is surrounded with walls, and contains 540 houses, with 4650 inhabitants, who carry on linen, woollen, and cotton manufactures, as well as breweries and distilleries. Long. 14. 15. E. Lat. 52. 32. N.

GARDEN, FRANCIS, better known as one of the Lords of Session in Scotland, under the title of Lord Gardenstone, was born at Edinburgh on the 24th of June, in the year 1721. His father was Alexander Garden of Troup, an opulent landholder in Aberdeenshire; and his mother Jane, daughter of Sir Francis Grant of Cullen. After passing through the usual course of liberal education at the school and the university, he betook himself to the study of law; and in the year 1744 was admitted a member of the Faculty of Advocates.

In his practice as advocate he soon began to be distinguished by a native rectitude of understanding; by that vivacity of apprehension and imagination which is commonly denominated genius; by manly candour in argument, often more persuasive than subtilty and sophistical artifice; and by powers which, with diligence, might easily have conducted him to the highest eminence in the profession. But the same strength, openness, and ardour of mind, which distinguished him so advantageously at the bar, tended to give him a fondness for the gay enjoyments of convivial intercourse, which was unfavourable to his progress in juridical erudition. Shining in the social and convivial circle, he became less ambitious than he might otherwise have been, of the character of an eloquent advocate, or of a profound and learned lawyer. The vivacity of his genius was averse from austere and plodding study, whilst it was captivated by the fascinations of polite learning and of the fine arts. He, however, became, in 1764, his majesty's solicitor-general for Scotland; and he was afterwards elevated to the bench, as a judge both in the Courts of Session and Justiciary.

In the year 1762 he purchased the estate of Johnston, in the county of Kincardine; and a few years afterwards he began to attempt a plan of the most liberal improvement of the value of this estate, by an extension of the village of Laurencekirk, adjoining. In the year 1779, he procured it to be erected into a burgh of barony, with a magistracy, an annual fair, and a weekly market. He provided in it a good inn for the reception of travellers, and furnished this inn with a library for their amusement. In the year 1785, upon the death of his elder brother, Lord Gardenstone succeeded to the possession of the family estates, which were considerable. His succession to an ample income, at a period when the vigour of his constitution was rapidly yielding to the infirmities of old age, enabled him to seek relief from his official duties, by a temporary residence on the Continent. In the month of September 1786, he set out from London for Dover, and passed over into France. After visiting Paris, he proceeded to Provence, and spent the winter months in the genial climate of Hiéres. In the spring of 1787 he returned northwards, visiting Geneva, Switzerland, the Netherlands, and the Dutch provinces, and passing through Germany into Italy. After an absence of about three years, he returned to his native country. His last years were spent in the discharge of the duties of his office as a judge; in social intercourse with his friends; in cherishing those fine arts, of which he was an eminent judge; and in promoting the comfort, and encouraging the industry of his dependents. St Bernard's Well, in the neighbourhood of Edinburgh, had long been distinguished for the medicinal virtues of its waters. But various circumstances had concurred to throw it into neglect. The qualities of this mineral water falling under Lord Gardenstone's notice, he was induced to purchase the property of the well; to direct it to be cleared from surrounding obstacles, which contaminated the virtues of the water, or made it inaccessible; to erect a beautiful and commodious edifice over it; and to appoint proper persons to distribute the water for a very trivial compensation to the public. As an amusement during the last two or three years of his life, when his increasing infirmities precluded him from more active exercise, and from mingling so frequently in the society of his friends as was agreeable to his social and convivial temper, he bethought himself of revising some of the *jeux d'esprit*, and light fugitive pieces, in which he had indulged the gaiety of his fancy in his earlier days; and a small volume of poems was published, in which the best pieces are, upon good authority, ascribed to Lord Gardenstone. He revised also the memoranda which he had made upon his travels, and permitted them to be sent to press. Two volumes were published, one after another, whilst his lordship was yet alive; the third appeared after his death. They met with a very favourable reception in the world, and were honoured with the high approbation of the most respectable writers of periodical criticism. His lordship's health had been long declining, and he died a bachelor, on the 22d of July 1793, lamented by his friends, and by all to whom his merits and virtues were known.

---

[1] Since the eclogues of John of the Encina, pastoral poetry had not made any progress in Spain. Garcilaso imitated the eclogues of Virgil and of Sannazaro, and in this imitation established the character of romantic poetry with the correctness of the ancients, so that his eclogues, one of which is a masterpiece, greatly surpass all the Italian pieces of the same description, if we except the *Arcadia* of Sannazaro. (*Littérature Espagnole*, tome i. p. 251.)

Garden, a piece of ground properly laid out for ornamental effect, or for the careful cultivation of fruits, flowers, and vegetable productions.

GARDENING,

The art of forming and cultivating garden grounds, whether of the Ornamental or Culinary kinds. The former, or Ornamental, commonly called Landscape Gardening, will be the subject of this article; the latter, or Culinary Gardening, will be treated of under the head of Horticulture.

I.—HISTORY OF GARDENING.

Gardening, as Mr Walpole observes,[1] was probably one of the first arts which succeeded to that of building houses, and naturally attended property and individual possession. Culinary, and afterwards medicinal herbs, were the objects of every head of a family; and it became convenient to have them within reach, without seeking them at random in woods, in meadows, or on mountains, as often as they were wanted. When the earth ceased to furnish spontaneously all those primitive luxuries, and cultivation became requisite, separate enclosures for rearing herbs were required. Fruits were in the same predicament; and those most in use, or which demand attention, must have entered into and extended the domestic enclosure. Noah, we are informed, planted a vineyard, and drank of the wine. Thus men acquired kitchen gardens, orchards, and vineyards. A cottage, and a slip of ground for a cabbage and a gooseberry bush, such as we see by the side of a common, were in all probability the earliest seats and gardens; a well and bucket succeeded to the Pison and Euphrates of Paradise. As settlements increased, the orchard and the vineyard followed; and the earliest princes of tribes possessed what are now only accounted the necessaries of a modern farmer. Matters, we may well believe, remained long in this situation; and we have reason to think that for many centuries the term *garden* implied no more than a kitchen-garden or orchard.

The garden of Alcinous, in the Odyssey, is the most renowned in the heroic times. Is there an admirer of Homer who can read his description of it without rapture, or who does not form to his imagination a scene of delights more picturesque than the landscapes of Tinian or Juan Fernandez? Yet what was that boasted Paradise with which

> the gods ordain'd
> To grace Alcinous and his happy land?

Why, divested of harmonious Greek and bewitching poetry, it was but a small orchard and vineyard, with some beds of herbs, and two fountains that watered them, enclosed within a quickset hedge. The whole compass of the celebrated garden enclosed only four acres of ground.

The garden of Alcinous was planted by the poet, and enriched by him with the gift of eternal summer, and was no doubt an effort of imagination surpassing any thing he had ever seen. As he has bestowed on the same happy prince a palace with brazen walls and columns of silver, he certainly intended that the garden should be proportionally magnificent. We are sure, therefore, that, as late as Homer's age, an enclosure of four acres, comprehending orchard, vineyard, and kitchen garden, was a stretch of luxury which the world at that time had never beheld.

Previously to this, however, we have in the sacred writings hints of a garden still more luxuriously furnished. We allude to the Song of Solomon, part of the scene of which is undoubtedly laid in a garden.[2] Flowers and fruits are particularly spoken of as the ornaments and the produce of it; and besides these, aromatic vegetables formed a considerable part of the gratification it afforded. The camphor and the cinnamon tree, with all trees of frankincense, and all the principal spices, flourished there.[1] Solomon tells us in another place,[2] that he made him great works, namely, gardens and orchards, and planted in them trees of every kind. Indeed we must suppose his gardens to have been both amply and curiously furnished, seeing that the kinds and properties of the vegetable tribes seem to have been a favourite study with the royal philosopher, and to have been deemed a subject worthy of his pen; for we are told that he wrote of plants, from the cedar of Lebanon down to the hyssop of the wall.[3] Fountains and streams of water appear also to have had a share in the composition.

[1] *History of Modern Gardening*, subjoined to the fourth volume of his *Anecdotes of Painting*.

[2] Chap. ii. 1.

The hanging gardens of Babylon formed a still greater prodigy. But as they are supposed to have been formed on terraces and the walls of the palace, whither soil had been conveyed on purpose, Mr Walpole concludes that they were what sumptuous gardens have been in all ages until the present, unnatural, enriched by art, possibly with fountains, statues, balustrades, and summer-houses, and any thing but verdant and rural. Others, however, have allowed them greater praise; and they seem, in many respects, to have been laid out with good taste. Their elevation not only produced a variety and extent of view, but was also useful in moderating the heat. Such a situation would likewise suit a greater variety of trees and plants than a plain surface, and would contain a larger as well as a more diversified extent. The suiting of the situation to the nature of the tree seems, from the account given by Josephus, to have been one view[4] in erecting the building in such a manner; and the success seems to have been answerable, as the trees are said to have flourished extremely well,[5] and to have grown as tall as in their native situations. On the whole, then, however different these may appear from modern gardens, they seem to have been formed with judgment and taste, and well adapted to the situation and circumstances in which they were placed.

It seems probable, from several circumstances, that the eastern gardens were adjoining to the house or palace to which they belonged. Thus, King Ahasuerus goes immediately from the banquet of wine to walk in the garden of the palace.[6] The garden of Cyrus at Sardis, mentioned by Xenophon,[7] was probably contiguous to the palace; as was that of Attalus, mentioned by Justin.[8] But the hanging gardens at Babylon were not so much adjacent to the palace, as part of the palace itself, since several of the royal apartments were beneath them.[9]

It is not clear what the taste for gardening was amongst the Greeks. The Academus, we know, was a wooded shady place; and the trees appear to have been of the olive species. It was situated beyond the limits of the walls, and adjacent to the tombs of the heroes; and though we are nowhere informed of the particular manner in which this grove was disposed or laid out, it may be gathered from Pausanias, in his Attica, that it was an elegant ornamented place. At the entrance was an altar dedicated to Love, which was said to have been the first erected to that deity. Within the Academus were the altars of Prometheus, of the Muses, of Mercury, of Minerva, and Hercules; and at a small distance was the tomb of Plato. So that in all probability it was highly adapted by art, as well as nature, to philosophic reflection and contemplation. We are told by Plutarch, that before the time of Cimon, the Academus was a rude uncultivated spot, which was planted by that general, who had water conveyed to it; but whether this water was brought merely for use to refresh the trees, or for ornament, does not appear. It was divided into gymnasia, or places of exercise, and philosophic walks shaded with trees; and these are said to have flourished very well, until destroyed by Sylla when he besieged Athens. Near the academy were the gardens of the philosophers, of Plato and of Epicurus; which, however, were probably but small. The scene of Plato's Dialogue concerning Beauty is elegantly described as being on the banks of the Ilissus, and under the shade of the plantain; but no artificial arrangement of objects is mentioned, nor any thing which can lead us to imagine the prospect to have been any other than merely natural.

Amongst the Romans, a taste for gardening, any otherwise than as a matter of utility, seems not to have prevailed till a very late period; at least the writers on husbandry, Cato, Varro, Columella, and Palladius, make not the least mention of a garden as an object of pleasure, but solely with respect to its productions of herbs and fruits. The gardens of Lucullus are the first we find mentioned of remarkable magnificence, though probably, from the extravagance to which these had arrived, they were not the first of the kind. Plutarch speaks of them as incredibly expensive, and equal to the magnificence of kings. They consisted of artificial elevations of ground to a surprising height, buildings projecting into the sea, and vast pieces of water made upon land. In short, his extravagance and expense were so great that he thence acquired the appellation of the Roman Xerxes. It is not improbable, from this account, and from the consideration that Lucullus had spent much time in Asia, in a situation in which he had an opportunity of observing the most splendid constructions of this kind, that these gardens were laid out in the Asiatic style. The vast masses of building said to have been erected might have borne some resemblance, in the arrangement and style, to the Babylonian gardens; and the epithet of the Roman Xerxes might be applicable to the taste as well as to the magnitude and expensive nature of his works.

The Tusculan villa of Cicero, though often mentioned, is not anywhere described in his works, so as to give an adequate idea of the style in which his gardens or grounds were disposed. And there is but little in Virgil relative to this subject. Pines,[10] it seems, were a favourite ornament in gardens; and flowers,[11] especially roses, were much esteemed, perfumes indeed having been always highly valued in warm climates. Virgil places Anchises in Elysium in a grove of bays, and is careful to remark that they were of the sweet-scented kind. The Pæstan roses were chiefly valued for their excellent odour; and on account of this quality they were placed by Tibullus as ornaments in the Elysian fields. There appears also to have prevailed amongst the Romans a piece of luxury relative to gardens, which is equally prevalent amongst us, namely, the forcing of flowers at seasons of the year not suited to their natural blowing.

When Roman authors, whose climate instilled a wish for cool retreats, speak of their enjoyments of this kind, they sigh for grottoes, caves, and the refreshing hollows of mountains, near irriguous and shady fountains; or boast of their porticoes, walks of planes, canals, baths, and breezes from the sea. Their gardens are almost never mentioned except as affording shade and shelter from the rage of the dog-star. Pliny has left us descriptions of two of his villas. As he used his Laurentine villa as his winter retreat, it is not surprising that the garden should form no considerable part of the account. All he says of it is, that the *gestatio*, or place of exercise, which surrounded the garden, was bounded by a hedge of box, and, where that had perished, with rosemary; that there was a walk of vines; and that most of the trees were fig and mulberry, the soil not being proper for any other sorts. On the subject of his Tuscan villa he is more diffuse; and the garden forms a considerable part of the description. And what constituted the principal beauty of that pleasure-ground? Exactly what was the admiration of this country above a century ago; namely, box-trees cut into monsters, animals, letters, and the names of the master and the artificer. In an age when architecture displayed all its grandeur, all its purity, and all its taste; when there arose Vespasian's amphitheatre, the Temple of Peace, Trajan's forum, Domitian's baths, and Hadrian's villa, the ruins and vestiges of which still excite our astonishment and curiosity; a Roman consul, a polished emperor's friend, and a man of elegant literature and taste, delighted in what the mob now scarcely admire in a college garden. All the ingredients of Pliny's corresponded exactly with those laid out in this country on Dutch principles. He talks of slopes, terraces, a wilderness, shrubs methodically trimmed, a marble basin, pipes spouting water, a cascade falling into the basin, bay-trees planted alternately with planes, and a straight walk whence issued others parted off by hedges of box and apple trees, with obelisks placed between every two. There wants nothing but the embroidery of a parterre, to make a garden in the time of Trajan serve for a description of one in that of King William. In one passage indeed Pliny seems to have conceived that natural irregularity might be a beauty; *in opere urbanissimo*, says he, *subita velut illati ruris imitatio.* Something like a rural view was contrived amidst so much polished composition. But the idea soon vanished, lineal walks immediately enveloped the slight scene, and names and inscriptions in box again succeeded to compensate for the daring introduction of nature.

In the paintings found at Herculaneum there are a few traces of gardens, as may be seen in the second volume of the prints. They are all small enclosures, formed by trellis-work and espaliers, and regularly ornamented with vases, fountains, and caryatides, elegantly symmetrical, and proper for the narrow spaces allotted to the garden of a house in a capital city.

From what has been said, it appears how naturally and insensibly the idea of a kitchen-garden slid into that which has for so many ages been peculiarly termed a *garden*, and by our ancestors in this country distinguished by the name of a *pleasure-garden*. A square piece of ground was originally parted off for the use of the family; and to exclude cattle, and ascertain the property, it was separated from the fields by a hedge. As pride and the desire of privacy increased, the enclosure was dignified by walls; and in climates where fruits were not lavished by the ripening glow of nature and soil, fruit-trees were assisted and sheltered from surrounding winds by the like expedient; for the inundation of luxuries, which have swelled into general necessities, have almost all taken their source from the simple fountain of reason.

When the custom of making square gardens enclosed with walls was thus established, to the exclusion of nature and prospect, pomp and solitude combined to call for something which might serve to enrich and enliven the insipid and unanimated partition. Fountains, first invented for use, received embellishments from costly marbles; and at last, to contradict utility, tossed their waste of waters into the air in spouting columns. Art, in the hands of rude man, had at first been made a succedaneum to nature; in the hands of ostentatious wealth, it became the means of opposing nature; and the more it traversed the march of the latter, the more nobility thought its power was demonstrated. Canals measured by the line were introduced instead of meandering streams, and terraces were hoisted aloft in opposition to the facile slopes which imperceptibly unite the valley to the hill. Balustrades defended those precipitate and dangerous elevations, and flights of steps reunited them to the subjacent flat from which the terrace had been raised. Vases and sculpture were added to these unnecessary balconies, and statues furnished the lifeless spot with mimic representations of the excluded sons of men. Thus difficulty and expense were the constituent parts of those sumptuous and selfish solitudes; and every improvement which was made seemed but a step farther from nature. The tricks of water-works to wet the unwary, not to refresh the panting spectator; and parterres embroidered in patterns like a petticoat; were but the childish endeavours of fashion and novelty to reconcile greatness to what it had surfeited on. To crown these impotent displays of false taste, the sheers were applied to the lovely wildness of form with which nature has distinguished each various species of tree and shrub. The venerable oak, the romantic beech, the useful elm, even the aspiring circuit of the lime, the regular round of the chestnut, and the almost moulded orange-tree, were corrected by fantastic and tasteless admirers of symmetry. The compass and square were of more use in plantations than the nurseryman. The measured walk, the quincunx, and the étoile, imposed their unsatisfying sameness on every royal and noble garden. Trees were headed, and their sides pared away; and many French groves seemed green chests set upon poles. Seats of marble, arbours, and summer-houses, terminated every vista; and symmetry, even where the space was too large to permit its being remarked at one view, was so essential, that, as Pope observed,

> each alley has a brother,
> And half the garden just reflects the other.

Knots of flowers were more defensibly subjected to the same regularity. Leisure "in trim gardens took his pleasure." In the garden of Marshal de Biron at Paris, consisting of fourteen acres, every walk was buttoned on each side by lines of flower-pots.

It does not precisely appear what our ancestors meant by a bower; it was probably an arbour; sometimes it meant the whole frittered enclosure, and in one instance it certainly included a labyrinth. Rosamond's bower was indisputably of that kind; though, whether composed of walls or hedges, cannot be determined. A square and a round labyrinth were formerly so capital ingredients of a garden, that in the architecture of Du Cerceau, who lived in the time of Charles IX. and Henry III., there is scarcely a ground plot without one of each. In Kip's *Views of the Seats of our Nobility and Gentry*, we see the same tiresome and returning uniformity. Every house is approached by two or three gardens, consisting perhaps of a gravel walk and two grass plats or borders of flowers. Each rises above the other by two or three steps, and as many walls and terraces, with so many iron gates, that we recollect those ancient romances in which every entrance was guarded by nymphs or dragons. Yet though these and such like preposterous inconveniences prevailed from age to age, good sense in this country had perceived the want of something at once more grand and more natural. These reflections, and the bounds set to the waste made by royal spoilers, gave origin to parks. The latter were contracted forests and extended gardens. Hentzner says, that according to Rous of Warwick, the first park was that at Woodstock. If so, it might be the foundation of a legend that Henry II. secured his mistress in a labyrinth; it was no doubt more difficult to find her in a park than in a palace, where the intricacy of the woods and various lodges buried in covert might conceal her actual habitation.

It is more extraordinary, that having so long ago stumbled on the principle of modern gardening, we should have persisted in retaining its reverse, symmetrical and unnatural gardens. That parks were rare in other countries, Hentzner, who travelled over a great part of Europe, leads us to suppose, by observing that they were common in England. In France they retained the name, but nothing was more different both in compass and disposition. Their parks were usually square or oblong enclosures, regularly planted with walks of chestnuts or limes, and generally every large town has one for its public recreation. "One man, one great man, we had," says Mr Walpole, "on whom nor education nor custom could impose their prejudices; who, 'on evil days though fallen, and with darkness and solitude compassed round,' judged that the mistaken and fantastical ornaments he had seen in gardens were unworthy of the Almighty hand that planted the delights of Paradise. He seems with the prophetic eye of taste to have conceived, nay to have foreseen, modern gardening; as Lord Bacon announced the discoveries since made by experimental philosophy. The description of Eden is a warmer and more just picture of the present style than Claud Lorraine could have painted from Hagley or Stourhead." Mr Walpole then quotes passages illustrative of this observation; and adds, "Recollect, that the author of this sublime vision had never seen a glimpse of any thing like what he has imagined; that his favourite ancients had dropped not a hint of such divine scenery; and that the conceits in Italian gardens were the brightest originals that his memory could furnish. But his intellectual eye saw a nobler plan, so little did he suffer by the loss of sight. It sufficed him to have seen the materials with which he could work. The vigour of a boundless imagination told him how a plan might be disposed that would embellish nature, and restore art to its proper office, the just improvement or imitation of it."

Let us now turn to an admired writer, posterior to Milton, and see how cold, how insipid, how tasteless, is his account of what he pronounced a perfect garden. We speak not of his style, which it was not necessary for him to animate with the colouring and glow of poetry. It is his want of ideas, of imagination, and of taste, that deserves censure, when he dictated on a subject which is capable of all the graces which a knowledge of beautiful nature can bestow. Sir William Temple was an excellent man; Milton, a genius of the first order. We cannot wonder that Sir William should declare in favour of parterres, fountains, and statues, as necessary to break the sameness of large grass plats, which he thinks have an ill effect upon the eye, when he acknowledges that he discovers fancy in the gardens of Alcinous. Milton studied the ancients with equal enthusiasm, but no bigotry; and he had the judgment to distinguish between the want of invention and the beauties of poetry. Compare his paradise with Homer's garden, both ascribed to a celestial design. For Sir William, it is just to observe that his ideas centred in a fruit garden. He had the honour of giving to his country many delicate fruits, and he thought of little else than disposing them to the best advantage.

"The best figure of a garden," says he, "is either a square or an oblong, and either upon a flat or a descent; they have all their beauties, but the best I esteem an oblong upon a descent. The beauty, the air, the view, make amends for the expense, which is very great in finishing and supporting the terrace walks, in levelling the parterres, and in the stone stairs that are necessary from one to the other. The perfectest figure of a garden I ever saw, either at home or abroad, was that of Moor Park in Hertfordshire, when I knew it about thirty years ago. It was made by the Countess of Bedford, esteemed amongst the greatest wits of her time, and celebrated by Dr Donne; and with very great care, excellent contrivance, and much cost; but greater sums may be thrown away without effect or honour, if there want sense in proportion to money, or if nature be not followed, which I take to be the great rule in this, and perhaps in every thing else, as far as the conduct not only of our lives but our governments. (We shall presently see how natural this admired garden was.) Because I take the garden I have named to have been in all kinds the most beautiful and perfect, at least in the figure and disposition, that I have ever seen, I will describe it for a model to those that meet with such a situation, and are above the regards of common expense. It lies on the side of a hill, upon which the house stands, but not very steep. The length of the house, where the best rooms and of most use or pleasure are, lies upon the breadth of the garden; the great parlour opens into the middle of a terrace gravel walk that lies even with it, and which may be, as I remember, about three hundred paces long, and broad in proportion; the border set with standard laurels and at large distances, which have the beauty of orange-trees out of flower and fruit. From this walk are three descents by many stone steps, in the middle and at each end, into a very large parterre. This is divided into quarters by gravel walks, and adorned with two fountains and eight statues in the several quarters. At the end of the terrace walk are two summer-houses, and the sides of the parterre are ranged with two large cloisters open to the garden, upon arches of stone, and ending with two other summer-houses even with the cloisters, which are paved with stone, and designed for walks of shade, there being none other in the whole parterre. Over these two cloisters are two terraces covered with lead and fenced with balusters; and the passage into these airy walks is out of the two summer-houses at the end of the first terrace walk. The cloister facing the south is covered with vines, and would have been proper for an orange-house, and the other for myrtles or other more common greens, and had, I doubt not, been cast for that purpose, if this piece of gardening had been then in as much vogue as it is now. From the middle of this parterre is a descent by many steps flying on each side of a grotto, that lies between them, covered with lead and flat, into the lower garden, which is all fruit-trees ranged about the several quarters of a wilderness, which is very shady; the walks here are all green, the grotto embellished with figures of shell rock-work, fountains, and water-works. If the hill had not ended with the lower garden, and the wall were not bounded by a common way that goes through the park, they might have added a third quarter of all greens; but this want is supplied by a garden on the other side the house, which is all of that sort, very wild, shady, and adorned with rough rock-work and fountains. This was Moor Park when I was acquainted with it, and the sweetest place, I think, that I have seen in my life, either before or since, at home or abroad."

It is unnecessary to add any remarks respecting this description. Any man might design and build as sweet a garden, who had been born in and never stirred out of Holborn. It was not, however, peculiar to Sir William Temple to think in this manner. How many Frenchmen are there who have seen our gardens, and still prefer unnatural flights of steps and shady cloisters covered with lead? Le Nautre, the architect of the groves and grottoes at Versailles, came hither on a mission to improve our taste, and planted St James' and Greenwich Parks; no great monuments, by the way, of his invention.

But, to do justice to Sir William Temple, we must not omit what he adds, "What I have said of the best forms of gardens is meant only of such as are in some sort regular; for there may be other forms wholly irregular, that may, for ought I know, have more beauty than any of the others; but they must owe it to some extraordinary dispositions of nature in the seat, or some great race of fancy or judgment in the contrivance, which may reduce many dis-agreeing parts into some figure, which shall yet, upon the whole, be very agreeable. Something of this I have seen in some places, but heard more of it from others who have lived much among the Chineses, a people whose way of thinking seems to lie as wide of ours in Europe as their country does. Their greatest reach of imagination is employed in contriving figures, where the beauty shall be great and strike the eye, but without any order or disposition of parts, that shall be commonly or easily observed. And though we have hardly any notion of this sort of beauty, yet they have a particular word to express it; and when they find it hit their eye at first sight, they say the Sharawadgi is fine or is admirable, or any such expression of esteem; but I should hardly advise any of these attempts in the figure of gardens among us; they are adventures of too hard achievement for any common hands; and though there may be more honour if they succeed well, yet there is more dishonour if they fail, and it is twenty to one they will; whereas in regular figures it is hard to make any great and remarkable faults."

Fortunately Kent and a few others were not quite so timid, or we might still be going up and down stairs in the open air. It is true, we have heard much, as Sir William Temple did, of irregularity and imitations of nature in the gardens or grounds of the Chinese. The former is certainly true; they are as whimsically irregular as European gardens were formally uniform and unvaried; but with regard to nature, it seems as much avoided as in the squares and oblongs and straight lines of our ancestors. An artificial perpendicular rock starting out of a flat plain, and connected with nothing, often pierced through in various places with oval hollows, has no more pretension to be deemed natural than a lineal terrace or a parterre. Mr Joseph Spence was so persuaded of the Chinese emperor's pleasure-ground being laid out on principles resembling ours, that he translated and published, under the name of Sir Harry Beaumont, a particular account of that enclosure, from the collection of the letters of the Jesuits. But except a determined irregularity, we can find nothing in it which gives any idea of attention being paid to nature. In short, this pretty gaudy style is the work of caprice and whim, and, when we reflect on the buildings, presents no image but that of unsubstantial tawdriness.

Having thus cleared our way by ascertaining what have been the ideas on gardening in all ages as far as we have materials to judge by, it remains to show to what degree Mr Kent invented the new style, and what hints he had received to suggest and conduct his undertaking. We have seen what Moor Park was when pronounced a standard. But as no succeeding generation in an opulent and luxurious country contents itself with the perfection established by its ancestors, more perfect perfection was still sought after; and improvements had gone on, till London and Wise stocked all our gardens with giants, animals, monsters, coats of arms, and mottoes, in yew, box, and holly. Absurdity could go no farther, and the tide turned. Bridgman, the next fashionable designer of gardens, was far more chaste; and, whether from good sense, or that the nation had been struck and reformed by an admirable paper in the Guardian (No. 173), he banished verdant sculpture, and did not even revert to the square precision of the foregoing age. He enlarged his plans, disdained to make every division tally to its opposite; and though he still adhered much to straight walks with high clipped hedges, they were only his great lines; the rest he diversified by wilderness, and with loose groves of oak, though still within surrounding hedges. As his reformation gained footing, he ventured, in the royal garden at Richmond, to introduce cultivated fields, and even morsels of a forest appearance, by the sides of those endless and tiresome walks which stretched out of one into another without intermission. But this was not until other innovators had also broken loose from rigid symmetry.

The capital stroke, however, the leading step to all that has followed, was the destruction of walls for boundaries, and the invention of fosses. A sunk fence may be called the *leading step.* No sooner was this simple enchantment made, than levelling, mowing, and rolling, followed. The contiguous ground of the park without the sunk fence was to be harmonized with the lawn within; and the garden in its turn was to be set free from its prime regularity, that it might assort with the wilder country without. The sunk fence ascertained the specific garden; but that it might not draw too obvious a line of distinction between the neat and the rude, the contiguous out-lying parts came to be included in a kind of general design; and when nature was taken into the plan, every step that was made pointed out new beauties and inspired new ideas. At that moment appeared Kent, painter enough to taste the charms of landscape, bold and opinionative enough to dare and to dictate, and born with a genius to strike out a great system from the twilight of imperfect essays. He leaped the fence, and saw that all nature was a garden. He felt the delicious contrast of hill and valley changing imperceptibly into each other, tasted the beauty of the gentle swell or concave scoop, and remarked how loose groves crowned an easy eminence with happy ornament, and, whilst they called in the distant view between their graceful stems, removed and extended the perspective by delusive comparison. Thus the pencil of his imagination bestowed all the arts of landscape on the scenes he handled. The great principles upon which he worked were perspective, and light and shade. Groups of trees broke too uniform or too extensive a lawn; evergreens and woods were opposed to the glare of the champaign; and where the view was less fortunate, or so much exposed as to be beheld at once, he blotted out some parts by thick shades, to divide it into variety, or to make the richest scene more enchanting by reserving it to a farther advance of the spectator's step. Thus selecting favourite objects, and veiling deformities by screens of plantation, and by sometimes allowing the rudest waste to add its foil to the richest theatre, he realized the compositions of the greatest masters in painting. Where objects were wanting to animate his horizon, his taste as an architect could bestow immediate termination. His buildings, his seats, his temples, were more the works of his pencil than of his compasses.

But of all the beauties which Kent added to the face of this beautiful country, none surpassed his management of water. Adieu now to canals, circular basins, and cascades tumbling down marble steps, that last absurd magnificence of Italian and French villas. The forced elevation of cataracts was no more. The gentle stream was taught to wind seemingly at its pleasure; and where discontinued by different levels, its course appeared to be concealed by thickets properly interspersed, and glittered again at a distance, where it might be supposed naturally to arrive. Its borders were smoothed, but preserved their waving irregularity. A few trees scattered here and there on its edges sprinkled the tame bank which accompanied its meanders; and when it disappeared among the hills, shades descending from the heights leaned towards its progress, and framed the distant point of light under which it was lost, as it turned aside to either hand of the blue horizon. Thus dealing in none but the colours of nature, and catching its most favourable features, men saw a new creation opening before their eyes. The living landscape was chastened or polished, not transformed. Freedom was given to the forms of trees; they extended their branches unrestricted; and where any eminent oak, or master beech, had escaped maiming and survived the forest, bush and bramble were removed, and all its honours were restored to distinguish and shade the plain. Where the united plumage of an ancient wood extended wide its undulating canopy, and stood venerable in its darkness, Kent thinned the foremost ranks, and left only as many detached and scattered trees as softened the approach of gloom, and blended a chequered light with the thus lengthened shadows of the remaining columns.

Succeeding artists have added new master-strokes to these touches, perhaps improved or brought to perfection some which have been named. The introduction of foreign trees and plants, which we owe principally to Archibald duke of Argyll, contributed essentially to the richness of colouring so peculiar to our modern landscape. The mixture of various greens, and the contrast of forms between our forest-trees and the northern and West Indian firs and pines, are improvements more recent than Kent, or but little known to him. The weeping willow, and every florid shrub, each tree of delicate or bold leaf, are new tints in the composition of our gardens. But just as are the encomiums which have been bestowed on Kent's discoveries, he was neither without assistance nor without faults. Mr Pope undoubtedly contributed to form his taste.[1] The design of the Prince of Wales' garden at Carlton House was evidently borrowed from the poet's at Twickenham. There was a little of affected modesty in the latter, when he said, that of all his works he was most proud of his garden. And yet it was a singular effort of art and taste to impress so much variety and scenery on a spot of five acres. The passing through the gloom from the grotto to the opening day, the retiring and again assembling shades, the dusky groves, the larger lawn, and the solemnity of the termination at the cypresses leading up to his mother's tomb, were managed with exquisite judgment; and though Lord Peterborough assisted him "to form his quincunx and to rank his vines," these were not the most pleasing ingredients of his little perspective.

Having routed professed art, Kent, like some reformers, knew not how to stop at the just limits. He had followed nature, and imitated her so happily, that he began to think all her works were equally proper for imitation. In Kensington Garden he planted dead trees, to give a greater air of truth to the scene; but he was soon laughed out of this excess. His ruling principle was, that nature abhors a straight line; and his imitators seemed to think that she could love nothing but what was crooked. Yet so many men of taste of all ranks devoted themselves to the new improvements, that it is surprising how much beauty was struck out, with so few absurdities. Still in some lights the reformation seems to have been pushed too far. Though an avenue crossing a park or separating a lawn, and intercepting views from the seat to which it leads, are capital faults; yet a great avenue cut through woods, perhaps before entering a park, has a noble air, and announces the habitation of some man of distinction. In other places, the total banishment of all particular neatness immediately about a house, which is frequently left gazing by itself in the middle of a park, is a defect. Sheltered and even close walks, in so very uncertain a climate as ours, are comforts ill exchanged for the few picturesque days which we enjoy; and whenever a family can purloin a warm and even something of an old-fashioned garden from the landscape designed for them by the undertaker in fashion, without interfering with the picture, they will find satisfaction in those days which do not invite strangers to come and see their improvements.

II.—PRINCIPLES OF GARDENING.

Gardening, in the perfection to which it has at length been brought in Britain, is entitled to a considerable rank amongst the liberal arts. It is, according to Wheatley, as superior to landscape painting as a reality to a representation; it is an exertion of fancy, a subject for taste, and being released from the restraints of regularity, and enlarged beyond the purposes of domestic convenience, the most beautiful, the most simple, the most noble scenes of nature, are all within its province. For it is no longer confined to the spots from which it takes its name; but, as already observed, it regulates also the disposition and embellishment of a park, a farm, or even a forest. The business of a gardener is to select and apply whatever is great, elegant, or characteristic in any of them; to discover and to show all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and to improve its beauties.

SECT. I.—MATERIALS OF GARDENING.

These may be divided into two general classes; *Natural* and *Factitious*.

I. The Natural Materials are, according to Wheatley's enumeration, Ground, Wood, Water, and Rocks.

1. *Ground.* By this is meant that portion of naked surface which is included within the place to be improved; whether that surface be swamp, lawn, roughet, or broken ground; and whether it be a height, a valley, a plain, or a composition of swells, dips, and levels. "Nothing," says Mr Gilpin, "gives so just an idea of the beautiful swellings of ground as those of water, where it has sufficient room to undulate and expand. In ground which is composed of very refractory materials, you are presented often with harsh lines, angular insertions, and disagreeable abruptnesses. In water, whether in gentle or in agitated motion, all is easy, all is softened into itself; and the hills and valleys play into each other in a variety of the most beautiful forms. In agitated water, abruptnesses indeed there are, but yet they are such abruptnesses as in some part or other unite properly with the surface around them, and are on the whole peculiarly harmonious. Now, if the ocean in any of these swellings and agitations could be arrested and fixed, it would produce that pleasing variety which we admire in ground. Hence it is common to fetch our images from water, and apply them to land; we talk of an undulating line, a playing lawn, and a billowy surface; and give a much stronger and more adequate idea by such imagery, than plain language could possibly present." The exertions of art, however, are here inadequate, and the artist ought not to attempt to create a mountain, a valley, or a plain; he should but rarely meddle even with the smaller inequalities of grounds. Rough and broken ground may generally be reduced to lawn, or hid with wood; and a swamp may be drained or covered with water, whilst lawn may be variegated at pleasure by wood, and sometimes by water.

2. *Wood*, as a general term, comprehends all trees and shrubs in whatever disposition; but it is specifically applied in a more limited sense, and in that sense we shall now use it. Every plantation must be either a *wood*, a *grove*, or a *clump*. A wood is composed both of trees and underwood, covering a considerable space. A grove consists of

---

[1] "Pope," says Lord Byron, "was the inventor of that boast of the English, *modern gardening*. He divides this honour with Milton. Hear Warton: 'It hence appears that the enchanting art of gardening, in which this kingdom claims a preference over every nation in Europe, chiefly owes its origin and its improvement to two great poets, Milton and Pope.'" (Byron's *Works*, vol. vi. p. 408.)

trees without underwood. A clump differs from either only in extent. It may be either close or open: when close, it is sometimes called a *thicket;* when open, a *group of trees;* but both are equally clumps, whatever may be the shape or situation.

One of the noblest objects in nature[1] is the *surface of a large thick wood,* commanded from an eminence, or seen from below hanging on the side of a hill. The latter is generally the more interesting object. Its aspiring situation gives it an air of greatness; its termination is commonly the horizon; and, indeed, if it be deprived of that splendid boundary, if the brow appear above it (unless some very peculiar effect characterizes that brow), it loses much of its magnificence. It is inferior to a wood which covers a less hill from the top to the bottom; for a whole space filled is seldom little. But a wood commanded from an eminence is generally no more than a part of the scene below; and its boundary is often inadequate to its greatness. To continue it, therefore, till it winds out of sight, or loses itself in the horizon, is generally desirable; but then the varieties of its surface grow confused as it retires; whilst those of a hanging wood are all distinct; the furthest parts are held up to the eye, and none are at a distance though the whole be extensive.

The varieties of a surface are essential to beauty. A continued smooth shaven level of foliage is neither agreeable nor natural; the different growths of trees commonly break it in reality, and their shadows still more in appearance. These shades are so many tints, which, undulating about the surface, are its greatest embellishment; and such tints may be produced with more effect, and more certainty, by a judicious mixture of greens; at the same time an additional variety may be introduced, by grouping and contrasting trees very different in shape from each other; and whether variety in the greens or in the forms be the design, the execution is often easy, and seldom to a certain degree impossible. In raising a young wood, it may be perfect. In old woods, there are many spots which may be either thinned or thickened; and there the characteristic distinctions should determine what to plant, or what to leave, at least they will often point out those which, as blemishes, ought to be taken away; and the removal of two or three trees will sometimes accomplish the design. The number of beautiful forms and agreeable masses which may decorate the surface is so great, that where the place will not admit of one, another is always ready; and as no delicacy of finishing is required, no minute exactness is worth regarding; great effects will not be disconcerted by small obstructions and little disappointments.

The contrasts, however, of masses and of groups must not be too strong where *greatness* is the character of the wood, for unity is essential to greatness; and if direct opposites be placed close together, the wood is no longer one object; it is only a confused collection of several plantations. But if the progress be gradual from the one to the other, shapes and tints widely different may assemble on the same surface; and each should occupy a very considerable space. A single tree, or a small cluster of trees, in the midst of an extensive wood, is in size but a speck, and in colour but a spot; the groups and the masses must be large to produce any sensible variety.

When, in a romantic situation, very broken ground is overspread with wood, it may be proper on the surface of the wood to mark the inequalities of the ground. Rudeness, not greatness, is the prevailing idea; and a choice directly the reverse of that which is productive of unity will produce it. Strong contrasts, even oppositions, may be eligible. The aim is rather to disjoin than to connect. A deep hollow may sink into dark green; an abrupt bank may be shown by a rising stage of aspiring trees, and a sharp ridge by a narrow line of conical shapes. Firs are of great use upon such occasions; their tint, their form, and their singularity, recommend them.

A hanging *wood of thin forest trees,* seen from below, is seldom pleasing; these few trees are by the perspective brought nearer together; it loses the beauty of a thin wood, and is defective as a thick one. The most obvious improvement, therefore, is to thicken it. But when seen from an eminence, a thin wood is often a lively and elegant circumstance in a view; it is full of objects; and every separate tree shows its beauty. To increase that vivacity which is the peculiar excellence of a thin wood, the trees should be characteristically distinguished both by their tints and their shapes; and such as for their airiness have been proscribed in a thick wood, are frequently the most eligible here. Differences also in their growths are a further source of variety; each should be considered as a distinct object, unless where a small number are grouped together; and then all that compose the little cluster must agree: But the groups themselves, for the same reason as the separate trees, should be strongly contrasted; the continued underwood is their only connection, and that is not affected by their variety.

Though the surface of a wood, when commanded, deserves all these attentions, yet the *outline* more frequently calls for our regard; it is also more in our power; it may sometimes be great, and may always be beautiful. The first requisite is irregularity. That a mixture of trees and underwood should form a long straight line, can never be natural; and a succession of easy sweeps and gentle rounds, each a portion of a greater or less circle, composing all together a line literally serpentine, is if possible worse. It is but a number of regularities put together in a disorderly manner, and equally distant from the beautiful both of art and of nature. The true beauty of an outline consists more in breaks than in sweeps; rather in angles than in rounds; in variety, not in succession.

Every variety in the outline of a wood must be a *prominence* or a *recess.* Breadth in either is not so important as length to the one and depth to the other. If the former ends in an angle, the latter diminishes to a point; they may have more force than a shallow dent, or a dwarf excrescence, how wide soever. They are greater deviations from the continued line which they are intended to break; and their effect is to enlarge the wood itself, which seems to stretch from the most advanced point, back beyond the most distant to which it retires. The extent of a large wood on a flat, not commanded, can by no circumstance be so manifestly shown as by a deep recess; especially if that recess wind so as to conceal the extremity, and leave the imagination to pursue it. On the other hand, the poverty of a shallow wood might sometimes be relieved by here and there a prominence, or clumps which by their apparent junction should seem to be prominences arising out of it. A deeper wood with a continued outline, except when commanded, would not appear so considerable.

An inlet into a wood seems to have been cut, if the opposite points of the entrance tally; and such a show of art depreciates its merit; but a difference only in the situation of these points, by bringing one more forward than the other, prevents the appearance, though their forms be similar. Other points, which distinguish the great parts, should in general be strongly marked. A short turn has more spirit in it than a tedious circuit; and a line broken by angles has a precision and firmness which in an undulated line are wanting; the angles indeed should commonly be a little softened; the rotundity of the plant which forms them is sometimes sufficient for the purpose; but if they are mellowed down too much, they lose all meaning. Three or four large parts thus boldly distinguished will break a very long outline. When two woods are opposed on the sides of a narrow glade, neither has so much occasion for variety in itself as if it were single; if they are very different from each other, the contrast supplies the deficiency to each, and the interval between them is full of variety. The form of that interval is indeed of as much consequence as their own. Though the outlines of both the woods be separately beautiful, yet if together they do not cast the open space into an agreeable figure, the whole scene is not pleasing; and a figure is never agreeable when the sides too closely correspond. Whether they are exactly the same, or exactly the reverse of each other, they appear equally artificial.

---

[1] See Wheatley's *Observations on Modern Gardening.*

Every variety of outline hitherto mentioned may be traced by the underwood alone; but frequently the same effects may be produced with more ease, and with much more beauty, by a few trees standing out from the thicket, and belonging, or seeming to belong, to the wood, so as to make a part of its figure. Even where they are not wanted for that purpose, detached trees are such agreeable objects, so distinct, so light, when compared to the covert about them, that, skirting along it in some parts, and breaking it in others, they give an unaffected grace, which cannot otherwise be given to the outline. They have a still further effect when they stretch across the whole breadth of an inlet or before part of a recess into the wood; they are themselves shown to advantage by the space behind them; and that space, when seen between their stems, they in return throw into an agreeable perspective.

The prevailing character of a wood is generally grandeur. The principal attention which it requires, therefore, is to prevent the excesses of that character, to diversify the uniformity of its extent, to lighten the unwieldiness of its bulk, and to blend graces with greatness. The character of a *grove* is beauty. Fine trees are lovely objects. A grove is an assemblage of these, in which every individual retains much of its own peculiar elegance, and whatever it loses is transferred to the superior beauty of the whole. To a grove, therefore, which admits of endless variety in the disposition of the trees, differences in their shapes and their greens are seldom very important, and sometimes they are detrimental. Strong contrasts scatter trees which are thinly planted, and which have not the connection of underwood; they no longer form one plantation; they are a number of single trees. A thick grove is not indeed exposed to this mischief, and certain situations may recommend different shapes and different greens for their effects upon the surface; but in the outline they are seldom much regarded. The eye, attracted into the depth of the grove, passes by little circumstances at the entrance; even varieties in the form of the line do not always engage the attention; they are not so apparent as in a continued thicket, and are scarcely seen if they are not considerable.

But the surface and the outline are not the only circumstances which should be attended to. Though a grove be beautiful as an object, it is besides delightful as a spot to walk or to sit in; and the choice and the disposition of the trees for effects within, are therefore a principal consideration. Mere irregularity alone will not please; strict order is there more agreeable than absolute confusion, and some meaning better than none. A regular plantation has a degree of beauty, but it gives no satisfaction, because we know that the same number of trees might be more beautifully arranged. A disposition, however, in which the lines only are broken, without varying the distances, is equally improper. The trees should gather into groups, or stand in various irregular lines, and describe various figures; the intervals between them should be contrasted both in shape and in dimensions; a large space should in some places be quite open, whilst in others the trees should be so close together as hardly to leave a passage between them; and in others as far apart as the connection will admit. In the forms and the varieties of these groups, these lines, and these openings, principally consists the interior beauty of a grove.

The force of them is most strongly illustrated at Claremont, where the walk to the cottage, though destitute of many natural advantages, and eminent for none, though it commands no prospect, though the water below it is a trifling pond, though it has nothing, in short, but inequality of ground to recommend it, is yet the finest part of the garden; for a grove is there planted in a gently curved direction, all along the side of a hill, and on the edge of a wood, which rises above it. Large recesses break it into several clumps, which hang down the declivity; some of them approaching, but none reaching quite to the bottom. These recesses are so deep as to form great openings in the midst of the grove; they penetrate almost to the covert; but the clumps being all equally suspended from the wood, and a line of open plantation, though sometimes narrow, running constantly along the top, a continuation of grove is preserved, and the connection between the parts is never broken. Even a group which near one of the extremities stands out quite detached, is still in style so similar to the rest as not to lose all relation. Each of these clumps is composed of several others still more intimately united; each is full of groups, sometimes of no more than two trees, sometimes of four or five, and now and then in larger clusters; an irregular waving line, issuing from some little crowd, loses itself in the next; or a few scattered trees drop in a more distant succession from the one to the other. The intervals, winding here like a glade, and widening there into broader openings, differ in extent, in figure, and in direction; but all the groups, the lines, and the intervals, are collected together into large general clumps, each of which is at the same time both compact and free, identical and various. The whole is a place wherein to tarry with secure delight, or saunter with perpetual amusement.

The grove at Esher Place was planted by the same masterly hand; but the necessity of accommodating the young plantation to some large trees which grew there before has confined its variety. The groups are few and small; there was not room for larger or for more; there were no opportunities to form continued narrow glades between opposite lines; the vacant spaces are therefore chiefly irregular openings, spreading every way, and great differences of distance between the trees are the principal variety; but the grove winds along the bank of a large river, on the side and at the foot of a very sudden ascent, the upper part of which is covered with wood. In one place it presses close to the covert, retires from it in another, and stretches in a third across a bold recess, which runs up high into the thicket. The trees sometimes overspread the flat below, sometimes leave an open space to the river, at other times crown the brow of a large knoll, climb up a steep, or hang on a gentle declivity. These varieties in the situation more than compensate for the want of variety in the disposition of the trees; and the many happy circumstances which concur,

> In Esher's peaceful grove,
> Where Kent and nature vie for Pelham's love,

render this little spot more agreeable than any at Claremont. But though it was right to preserve the trees already standing, and not to sacrifice great present beauties to still greater in futurity, yet this attention has been a restraint; and the grove at Claremont, considered merely as a plantation, is, in delicacy of taste and fertility of invention, superior to that at Esher.

It is, however, possible to secure both a present and a future effect, by fixing first on a disposition which will be beautiful when the trees are large, and then intermingling another which is agreeable while they are small. These occasional trees are hereafter to be taken away; and must be removed in time, before they become prejudicial to the others.

The consequence of variety in the disposition is variety in the light and shade of the grove, which may be improved by the choice of the trees. Some are impenetrable to the fiercest sunbeam; others let in here and there a ray between the large masses of their foliage; and others, thin both of boughs and of leaves, only chequer the scene around. Every degree of light and shade, from a glare to obscurity, may be managed, partly by the number, and partly by the texture of the trees. Differences only in the manner of their growths have also corresponding effects; there is a closeness under those the branches of which descend low and spread wide; a space and liberty where the arch above is high; and frequent transitions from the one to the other are very pleasing. Still these are not all the varieties of which the interior of a grove is capable; trees, indeed, whose branches nearly reach the ground, being each a sort of thicket, are inconsistent with an open plantation; but though some of the characteristic distinctions are thereby excluded, other varieties more minute succeed in their place; for the freedom of passage throughout brings every tree in its turn near to the eye, and subjects even differences in foliage to observation. These, slight as they may seem, are agreeable when they occur; it is true, they are not regretted when wanting; but a defect of ornament is not necessarily a blemish.

It has been already observed, that *clumps* differ only in extent from woods, if they are close; or from groves, if they are open. They are small woods and small groves, governed by the same principles as the larger, allowances being made for their dimensions. But besides the properties they may have in common with woods or with groves, they have others peculiar to themselves which require examination. They are either *independent* or *relative.* When independent, their beauty, as single objects, is solely to be attended to; when relative, the beauty of the individuals must be sacrificed to the effect of the whole, which is the greater consideration.

The *occasions* on which independent clumps may be applied are many. They are often desirable as beautiful objects in themselves; they are sometimes necessary to break an extent of lawn, or a continued line whether of ground or of plantation; but on all occasions a jealousy of art constantly attends them, which irregularity in their figure will not always alone remove. Though elevations show them to advantage, yet a hillock evidently thrown up on purpose to be crowned with a clump, is artificial to a degree of disgust. Some of the trees should therefore be planted on the sides, to take off that appearance. The same expedient may be applied to clumps placed on the brow of a hill, to interrupt its sameness. They will have less ostentation of design, if they are in part carried down either declivity. The objection already made to planting many along such a brow, is on the same principle. A single clump is less suspected of art; if it be an open one, there can be no finer situation for it, than just at the point of an abrupt hill, or on a promontory into a lake or a river. It is in either a beautiful termination, distinct by its position, and enlivened by an expanse of sky or of water about and beyond it. Such advantages may balance little defects in its form; but they are lost if other clumps are planted near it. Art then intrudes, and the whole is displeasing.

But though a multiplicity of clumps, when each is an independent object, seldom seems natural; yet a number of them may, without any appearance of art, be admitted into the same scene, if they bear a *relation* to each other. If by their succession they diversify a continued outline of wood, if between them they form beautiful glades, if altogether they cast an extensive lawn into an agreeable shape, the *effect* prevents any scrutiny into the means of producing it. But when the reliance on that effect is so great, every other consideration must give way to the beauty of the whole. The figure of the glade, of the lawn, or of the wood, is principally to be attended to. The finest clumps, if they do not fall easily into the great lines, are blemishes; their connections and their contrasts are more important than their forms.

3. *Water.* All inland water is either *running* or *stagnant.* When stagnant, it forms a *lake* or a *pool,* which differ only in extent; whilst a *pool* and a *pond* are the same. Running waters are either a *river*, a *rivulet*, or a *rill;* and these differ only in breadth. A *rivulet* and a *brook* are synonymous terms; a *stream* and a *current* are general names for all.

Space or expansion is essential to a *lake.* It cannot be too large as a subject of description or of contemplation; but the eye receives little satisfaction when it has not a form on which to rest. The ocean itself hardly atones by all its grandeur for its infinity; and a prospect of it is, therefore, always most agreeable, when in some part, at no great distance, a reach of shore, a promontory, or an island, reduces the immensity into shape. An artificial lake, again, may be comparatively extravagant in its dimensions. It may be so out of proportion to its appendages, as to seem a waste of water; for all size is in some respects relative. If this exceeds its due dimensions, and if a flatness of shore beyond it adds still to the dreariness of the scene, wood to raise the banks, and objects to distinguish them, are the remedies to be employed. If the length of a piece of water be too great for its breadth, so as to destroy all idea of circuity, the extremities should be considered as too far off, and made important to give them proximity; whilst at the same time the breadth may be favoured, by keeping down the banks on the sides. On the same principle, if the lake be too small, a low shore will, in appearance, increase the extent.

But it is not necessary that the whole scene be bounded. If form be impressed on a considerable part, the eye can, without disgust, permit a large reach to stretch beyond its ken; it can even be pleased to observe a tremulous motion in the horizon, which shows that the water has not yet there attained its termination. Still short of this, the extent may be kept in uncertainty; a hill or a wood may conceal one of the extremities, and the country beyond it, in such a manner as to leave room for the supposed continuation of so large a body of water. Opportunities to choose this shape are frequent, and it is the most perfect of any. The scene is closed, but the extent of the lake is undetermined; a complete form is exhibited to the eye, whilst a boundless range is left open to the imagination.

But mere form will only give content, not delight; that depends upon the outline, which is capable of exquisite beauty; and the *bays*, the *creeks*, and the *promontories*, which are ordinary parts of that outline, together with the accidents of *islands*, of *inlets*, and of *outlets* to rivers, are in their shapes and their combinations an inexhaustible fund of variety.

Bays, creeks, and promontories, however, though extremely beautiful, should not be very numerous. For a shore broken into little points and hollows has no certainty of outline; it is only ragged, not diversified; and the distinctness and simplicity of the great parts are hurt by the multiplicity of subdivisions. But islands, though the channels between them be narrow, do not so often derogate from greatness. They intimate a space beyond them the boundaries of which do not appear, and remove to a distance the shore which is seen in perspective between them. Such partial interruptions of the sight suggest ideas of extent to the imagination.

Though the windings of a *river* are proverbially descriptive of its course, yet, without being perpetually wreathed, it may be natural. Nor is the character expressed only by the turnings. On the contrary, if these are too frequent and sudden, the current is reduced into a number of separate pools, and the idea of progress is obscured by the difficulty of tracing it. Length is the strongest symptom of continuation. Long reaches are therefore characteristic of a river, and they conduce much to its beauty; each is indeed a considerable piece of water, and variety of beautiful forms may be given to their outlines.

A river requires a number of *accompaniments*. The changes in its course furnish a variety of situations; whilst the fertility, convenience, and amenity, which attend it, account for all appearances of inhabitants and improvement. Profusion of ornament on a fictitious river is a just imitation of cultivated nature. Every species of building, every style of plantation, may abound on the banks; and, whatever be their characters, their proximity to the water is commonly the happiest circumstance in their situation. A lustre is from thence diffused on all around; each derives an importance from its relation to this capital feature; those which are near enough to be reflected immediately belong to it, those at a greater distance still share in the animation of the scene; and objects totally detached from each other, being all attracted towards the same interesting connection, are united into one composition.

In the front of Blenheim was a deep broad valley, which abruptly separated the castle from the lawn and the plantations before it; even a direct approach could not be made without building a monstrous bridge over the vast hollow; but this forced communication was only a subject of raillery; and the scene continued broken into two parts, absolutely distinct from each other. This valley has been flooded, but not filled; the bottom only is covered with water, and the sides are still very high; but they are no longer the steeps of a chasm; they are the bold shores of a noble river. The same bridge is standing without alteration; but no extravagance remains; the water gives it propriety. Above it the river first appears, winding from behind a small thick wood in the valley; and soon taking a determined course, it is then broad enough to admit an island filled with the finest trees; others corresponding to them in growth and disposition stand in groups on the banks, intermixed with younger plantations. Immediately below the bridge the river spreads into a large expanse; the sides are open lawn. On that farthest from the house formerly stood the palace of Henry II. celebrated in many an ancient ditty by the name of Fair Rosamond's Bower. A clear little spring which rises there is by the country people still called Fair Rosamond's Well. The spot is now marked by a single willow, and near it is a fine collateral stream, of a beautiful form, retaining its breadth as far as it is seen, and retiring at last from the view behind a hill. The main river, having received this accession, makes a gentle bend; then continues for a considerable length in one wide direct reach; and, just as it disappears, throws itself down a high cascade, which is the present termination. Upon one of the banks of this reach is the garden. The steeps are there diversified with thickets and with glades; but the covert prevails, and the top is crowned with lofty trees. On the other side there is a noble hanging wood in the park. It was depreciated when it sunk into a hollow, and was poorly lost in the bottom; but it is now a rich appendage to the river, falling down an easy slope quite to the water's edge, where, with overshadowing, it is reflected on the surface. Another face of the same wood borders the collateral stream with an outline more indented and various; whilst a very large irregular clump adorns the opposite declivity. This clump is at a considerable distance from the principal river; but the stream it belongs to brings it down to connect with the rest; and the other objects, which were before dispersed, are now, by the interest of each in a relation which is common to all, collected into one illustrious scene. The castle itself is a prodigious pile of building, which, with all the faults of the architecture, will never seem other than a truly princely habitation; and the confined spot where it was placed, on the edge of an abyss, is converted into a proud situation, commanding a beautiful prospect of water, and open to an extensive lawn, adequate to the mansion, and an emblem of its domain. In the midst of this lawn stands a column, a stately trophy, recording the exploits of the Duke of Marlborough and the gratitude of Britain. Between this pillar and the castle is the bridge, which now, applied to a subject worthy of it, is established in all the importance due to its greatness. The middle arch is wider than the Rialto, but not too wide for the occasion; and yet that is the narrowest part of the river; but the length of the reaches is everywhere proportioned to their breadth. Each of them is alone a noble piece of water; and the last, the finest of all, loses itself gradually in a wood, which on that side is also the boundary of the lawn, and rises into the horizon. All is great in the front of Blenheim; but in that vast space no void appears, so important are the parts, so magnificent is the object. The plain is extensive, the valley broad, and the wood deep. Though the intervals between the building are large, they are filled with the grandeur which buildings of such dimensions and so much pomp diffuse all around them; and the river, in its long and varied course, approaching to every object, and touching upon every part, spreads its influence over the whole.

In the composition of this scene, the river, both as a part itself, and as uniting the other parts, has a principal share. But water is not lost though it be in so confined or so concealed a spot as to enter into no view; it may render that spot delightful. It is capable of the most exquisite beauty in its form; and though not in space, may yet in disposition have pretensions to greatness; for it may be divided into several branches, which will form a cluster of islands all connected together, make the whole place irriguous, and, instead of extent, supply a quantity of water. Such a sequestered scene usually owes its retirement to the trees and the thickets with which it abounds; but, in the disposition of these, one distinction should be constantly attended to. A river flowing through a wood which overspreads one continued surface of ground, and a river between two woods, are in very different circumstances. In the latter case the woods are separate; they may be contrasted in their forms and their characters, and the outline of each should be forcibly marked. In the former, no outline ought to be decernible; for the river passes between trees, not between boundaries; and though in the progress of its course the style of the plantations may often be changed, yet on the opposite banks a similarity should constantly prevail, that the identity of the wood may never be doubtful.

A river between two woods may enter into a view; and then it must be governed by the principles which regulate the conduct and the accompaniments of a river in an open exposure. But when it runs through a wood, it is never to be seen in a prospect; the place is naturally full of obstructions; and a continued opening, large enough to receive a long reach, would seem an artificial cut. The river must therefore necessarily wind more than in crossing a lawn where the passage is entirely free. But its influence will never extend so far on the sides. The buildings must be near the banks, and, if numerous, will seem crowded, being all in one tract, and in situations nearly alike. The scene, however, does not want variety; on the contrary, none is capable of more. The objects are not indeed so different from each other as in an open view; but they are very different, and in much greater abundance; for this is the interior of a wood, where every tree is an object, every combination of trees a variety, and no large intervals are requisite to distinguish the several dispositions; the grove, the thicket, or the groups, may prevail, and their forms and their relations may be constantly changed, without restraint of fancy, or limitation of number.

Water is so universally and so deservedly admired in a prospect, that the most obvious thought in the management of it is to lay it as open as possible, and purposely to conceal it would generally seem a severe self-denial; yet so many beauties may attend its passage through a wood, that larger portions of it might be allowed to such retired scenes than are commonly spared from the view, and the different parts in different styles would be fine contrasts to each other. If the water at Wotton[1] were all exposed, a walk of near two miles along the banks would be of a tedious length, from the want of those changes of the scene which now supply, through the whole extent, a succession of perpetual variety. The extent is so large as to admit of a division into four principal parts, all of them great in style and in dimensions, and differing from each other both in character and in situation. The first two are the least. The one is a reach of river, about the third of a mile in length, and of a competent breadth, flowing through a lovely meadow, open in some places to views of beautiful hills in the country, and adorned in others with clumps of trees so large that their branches stretch quite across, and form a high arch over the water. The next seems to have been a formal basin encompassed with plantations, and the appendages on either side still retain some traces of regularity, but the shape of the water is free from them; the size is about fourteen acres; and out of it issue two broad collateral streams winding towards a large river, which they are seen to approach and supposed to join. A real junction is however impossible, from the difference of the levels; but the terminations are so artfully concealed, that the deception is never suspected, and when known is not easily explained. The river is the third great division of the water; a lake into which it falls is the fourth. These two do actually join, but their characters are directly opposite; the scenes which they belong to are totally distinct, and the transition from the one to the other is very gradual; for an island near the conflux, dividing the breadth, and concealing the end of the lake, moderates for some way the space; and permitting it to expand by degrees, raises an idea of greatness from uncertainty accompanied with increase. The reality does not disappoint the expectation; and the island, which is the point of view, is itself equal to the scene. It is large and high above the lake; the ground is irregularly broken; thickets hang on the sides; and towards the top is placed an Ionic portico, which commands a noble extent of water, not less than a mile in circumference, bounded on one side with wood, and open on the other to two sloping lawns, the least of an hundred acres, diversified with clumps and bordered by plantations. Yet this lake, when full in view, and with all the importance which space, form, and situation can give, is not more interesting than the sequestered river, which has been mentioned as the third great division of the water. It is just within the verge of a wood, three quarters of a mile long, and everywhere broad, whilst its course is such as to admit of infinite variety without any confusion. The banks are cleared of underwood, but a few thickets still remain, and on one side an impenetrable covert soon begins; the interval is a beautiful grove of oaks, scattered over a green sward of extraordinary verdure. Between these trees and these thickets the river seems to glide gently along, constantly winding, without one short turn or one extended reach in the whole length of the way. This even temper in the stream suits the scenes through which it passes; they are in general of a very sober cast, not melancholy, but grave; never exposed to a glare, never darkened with gloom, nor, by strong contrasts of light and shade, exhibiting the excess of either. Undisturbed by an extent of prospect without, or a multiplicity of objects within, they retain at all times a mildness of character; which is still more forcibly felt when the shadows grow faint as they lengthen, when a little rustling of birds in the spray, the leaping of the fish, and the fragrance of the woodbine, denote the approach of evening; whilst the setting sun shoots its last gleams on a Tuscan portico, which is close to the great basin, but which from a seat near this river is seen at a distance, through all the obscurity of the wood, glowing on the banks, and reflected on the surface of the water. In another still more distinguished spot is built an elegant bridge, with a colonnade upon it, which not only adorns the place where it stands, but is also a picturesque object to an octagon building near the lake, where it is shown in a singular situation, overarched, encompassed, and backed with wood, without any appearance of the water beneath. This building, in return, is also an object from the bridge; and a Chinese room, in a little island just by, is another. Neither of them is considerable, and the others which are visible are at a distance; but more or greater adventitious ornaments are not required in a spot so rich as this in beauties peculiar to its character. A profusion of water pours in from all sides round upon the view; the opening of the lake appears, and a glimpse is caught of the large basin. One of the collateral streams is full in sight, and the bridge itself is in the midst of the finest part of the river; all seem to communicate the one with the other. Though thickets often intercept, and groups perplex the view, yet they never break the connection between the several pieces of water; each may still be traced along large branches or little catches, which in some places are overshadowed and dim, in others glisten through a glade, or glimmer between the holes of trees in a distant perspective; and in one, where they are quite lost to the view, some arches of the stone bridge, but partially seen among the wood, preserve their connection.

If a large river may sometimes, a smaller current undoubtedly may often, be conducted through a wood. It seldom adorns, it frequently disfigures, a prospect, where its course is marked, not by any appearance of water, but by a confined line of clotted grass, which disagrees with the general verdure. A *rivulet* may indeed have consideration enough for a home scene though it be open, but a *rill* is always most agreeable when most retired from public view. Its characteristic excellencies are vivacity and variety, which require attention, leisure, and silence, that the eye may pore upon the little beauties, and the ear listen to the low murmurs of the stream, without interruption. To such indulgence a confined spot only is favourable; a close copse is therefore often more acceptable than a high wood, and a sequestered valley at all times preferable to any open exposure. A single rill at a very little distance is a mere water-course; it loses all its charms; it has no importance in itself, and bears no proportion to the scene. A number of little streams have indeed an effect in any situation, but not as objects; they are interesting only on account of the character they express, and the irriguous appearance which they give to the whole.

---

[1] Vale of Aylesbury, Buckinghamshire.

The full tide of a large river has more force than activity, and seems too unwieldy to allow of very quick tranitions. But in a rill, the agility of its motions accounts or every caprice; frequent windings disguise its insigniicance; short turnings show its vivacity; sudden changes n the breadth are a species of its variety; and however antastically the channel may be wreathed, contracted, nd widened, it still appears to be natural. We find an musement in tracing the little stream through all the inricacies of its course, and in seeing it force a passage hrough a narrow strait, expatiate on every opportunity, truggle with obstructions, and puzzle out its way. A ivulet, which is the mean between a river and a rill, parakes of the character of both. It is not licensed to the xtravagance of the one, nor under the same restraints as he other; it may have more frequent bends than the iver, and longer reaches than a rill; the breadth of a tream determines whether the principal beauty results rom extent or from variety.

The murmurs of a rill are amongst the most pleasing ircumstances which attend it. If the bed of the stream e rough, mere declivity will occasion a constant rippling oise. When the current drops down a descent, though ut of a few inches, or forcibly bubbles up from a little ollow, it has a deep gurgling tone, not uniformly continud, but incessantly repeated, and therefore more engagng than any. The flattest of all is that sound rather of he splashing than the fall of water, which an even gentle lope, or a tame obstruction, will produce. This is less leasing than the others, but none should be entirely exluded; all in their turns are agreeable, and the choice of hem is much in our power By observing their causes we nay often find the means to strengthen, to weaken, or to hange them; and the addition or removal of a single stone r a few pebbles will sometimes be sufficient for the purpose.

A rill cannot pretend to any sound beyond that of a ittle waterfall. The roar of a cascade belongs only to a arger stream; but it may be produced by a rivulet to a onsiderable degree, and attempts to do more have geneally been unsuccessful. A vain ambition to imitate naure in her great extravagancies betrays the weakness of rt. Though a noble river, throwing itself headlong down precipice, be an object truly magnificent, it must, howver, be confessed, that in a single sheet of water there is formality which its vastness alone can cure. But the eight, not the breadth, is the wonder. When it falls not nore than a few feet, the regularity prevails; and its exent only serves to expose the vanity of affecting the style f a cataract in an artificial cascade. It is less exceptionable divided into several parts; for then each separate part nay be wide enough for its depth, and in the whole, vaiety, not greatness, will be the predominant character. ut a structure of rough, large, detached stones, cannot asily be contrived of strength sufficient to support a great eight of water; it is sometimes from necessity almost mooth and uniform, and then it loses much of its effect. everal little falls in succession are preferable to one great ascade which in figure or in motion approaches to regurity.

When greatness is thus reduced to number, and length ecomes of more importance than breadth, a rivulet vies ith a river; and it more frequently runs in a continued eclivity, which is very favourable to such a succession f falls. Half the expense and labour which are somemes bestowed on a river, to give it at the best a forced recipitancy in one spot only, would animate a rivulet hroughout the whole of its course. And, after all, the ost interesting circumstance in falling waters is their nimation. A great cascade fills us with surprise. But l surprise must cease; and the motion, the agitation, e rage, the froth, and the variety of the water, are finally the objects which engage the attention. For these a rivulet is sufficient; and they may there be produced without that appearance of effort which raises a suspicion of art.

Principles.

To obviate such a suspicion, it may sometimes be expedient to begin the descent out of sight; for the beginning is the difficulty. If that be concealed, the subsequent falls seem but a consequence of the agitation which characterizes the water at its first appearance; and the imagination is at the same time let loose to give ideal extent to the cascades. When a stream issues from a wood, such management will have a great effect. The bend of its course in an open exposure may afford frequent opportunities for it; and sometimes a low broad bridge may furnish the occasion. A little fall hid under the arch will create a disorder, in consequence of which a greater cascade below will appear very natural.

4. *Rocks.* Rocks are themselves too vast and too stubborn to submit to our control; by the addition or removal of appendages which we can command, parts may be shown or concealed, and the characters with their impressions may be weakened or enforced. To adopt the accompaniments, accordingly, is the utmost ambition of art when rocks are the subject.

Their most distinguishing characters are, *dignity*, *terror*, and *fancy*. The expressions of all are constantly wild; and sometimes a rocky scene is wild only, without pretensions to any particular character.

Rills, rivulets, and cascades, abound amongst rocks; they are natural to the scene; and such scenes commonly require every accompaniment which can be procured for them. Mere rocks, unless they are particularly adapted to certain impressions, though they may surprise, cannot be long engaging, if the rigour of their character be not softened by circumstances which may belong either to these or to more cultivated spots; and when the dreariness is extreme, little streams and waterfalls are of themselves insufficient for the purpose; an intermixture of vegetation is also necessary, and on some occasions even marks of inhabitants are proper.

Large clefts, sloping or precipitous, with a dale at bottom, furnish scenes of the wildest nature. In such spots, verdure alone will give some relief to the dreariness of the scene; and shrubs or bushes, without trees, are a sufficiency of wood. The thickets may also be extended by the creeping plants, such as pyracantha, vines, and ivy, to wind up the sides or cluster on the tops of the rocks. And to this vegetation may be added some symptoms of inhabitants, but they must be slight and few; the use of them is only to cheer, not to destroy, the solitude of the place; and such therefore should be chosen as are sometimes found in situations retired from public resort. A cottage may be lonely, but it must not here seem ruinous and neglected; it should be tight and warm, with every mark of comfort about it, to which its position in some sheltered recess may greatly contribute. A cavity also in the rocks, rendered easy of access, improved to a degree of convenience, and maintained in a certain state of preservation, will suggest similar ideas of protection from the bitterest inclemencies of the sky, and even of occasional refreshment and repose. But we may venture still further; a mill is of necessity often built at some distance from the town which it supplies; and here it would at the same time apply the water to a use, and increase its agitation. The dale may besides be made the haunt of those animals, such as goats, which are sometimes wild and sometimes domestic, and which, accidentally appearing, will divert the mind from the sensations natural to the scene, but not agreeable, if continued long without interruption. These and such other expedients will approximate the severest retreat to the habitations of men, and

Principles.

convert the appearance of a perpetual banishment into that of a temporary retirement from society.

But too strong a force on the nature of the place always fails. A winding path, which appears to be worn, not cut, has more effect than a high road, all artificial and level, which is too weak to overbear, and yet contradicts the general idea. The objects therefore to be introduced must be those which hold a mean between solitude and population, and the inclination of that choice towards either extreme should be directed by the degree of wildness which prevails; for though that runs sometimes to an excess which requires correction, at other times it wants encouragement, and at all times it ought to be preserved. It is the predominant character of rocks, which mixes with every other, and to which all the appendages must be accommodated; and they may be applied so as greatly to increase it. A licentious irregularity of wood and of ground, and a fantastic conduct of the streams, neither of which would be tolerated in the midst of cultivation, become and improve romantic rocky spots; even buildings, partly by their style, but still more by their position, in strange, difficult, or dangerous situations, distinguish and aggravate the native extravagancies of the scene.

Greatness is a chief ingredient in the character of dignity, with less of wildness than in any other. The effect here depends more upon amplitude of surface than variety of forms. The parts, therefore, must be large. If the rocks are only high, they are stupendous, not majestic; breadth is equally essential to their greatness; and every slender, every grotesque shape, is excluded. Art may interpose to show these large parts to the eye, and magnify them to the imagination, by taking away thickets which stretch quite across the rocks, so as to disguise their dimensions; or by filling with wood the small intervals between them, and thus, by concealing the want, preserving the appearance of continuation. When rocks retire from the eye down a gradual declivity, we can, by raising the upper ground, deepen the fall, lengthen the perspective, and give both height and extent to those at a distance. This effect may be still increased by covering that upper ground with a thicket, which shall cease or be lowered as it descends. A thicket, on other occasions, makes the rocks which rise out of it seem larger than they are. If they stand upon a bank overspread with shrubs, their beginning is at the least uncertain; and the presumption is, that they start from the bottom. Another use of this brushy underwood, is to conceal the fragments and rubbish which have fallen from the sides and the brow, and which are often unsightly. Rocks are seldom remarkable for the elegance of their forms; they are too vast and too rude to pretend to delicacy. But their shapes are often agreeable; and we can affect those shapes to a certain degree, at least we can cover many blemishes in them, by conducting the growth of shrubby and creeping plants about them.

For all these purposes mere underwood suffices; but for greater effects larger trees are requisite. They are worthy of the scene, and not only improvements, but accessions to its grandeur. We are used to class them amongst the noblest objects of nature; and when we see that they cannot aspire to the midway of the heights around them, the rocks are raised by the comparison. A single tree is therefore often preferable to a clump; the size, though really less, is more remarkable; and clumps are besides generally exceptionable in a very wild spot, from the suspicions of art which attends them; but a wood is free from that suspicion, and its own character of greatness recommends it to every scene of magnificence.

On the same principle, all possible consideration should be given to the streams. No given number of little rills are equal to one broad river; and in the principal current some varieties may be sacrificed to importance. But a degree of strength should always be preserved. The water, though it needs not be furious, should not be dull; for dignity, when most serene, is not languid, and space will hardly atone for want of animation.

This character does not exclude marks of inhabitants, though it never requires them to tame its wildness; and, without inviting, it occasionally admits an intermixture of vegetation. It even allows of buildings intended only to decorate the scene; but they must be adequate to it, both in size and in character. And if cultivation is introduced, that too should be conformable to the rest; not a single narrow patch cribbed out of the waste, but the confines of a country shelving into the vale, and suggesting the idea of extent. Nothing trivial ought to find admittance. But, on the other hand, no extravagance is required to support it; strange shapes in extraordinary positions, enormous weights unaccountably sustained, trees rooted in the sides, and torrents raging at the foot of the rocks, are at the best needless excesses. There is a temperance in dignity, which is rather hurt by a wanton violation of the common order of nature.

The terrors of a scene in nature are like those of a dramatic representation; they give an alarm, but the sensations are agreeable as long as they are kept to such as are allied only to terror, unmixed with any that are horrible and disgusting. Art may therefore be used to heighten them, to display the objects which are distinguished by greatness, to improve the circumstances which denote force, to mark those which intimate danger, and to blend withal here and there a cast of melancholy.

Greatness is as essential to the character of terror as to that of dignity. Vast efforts in little objects are ridiculous; nor can force be supposed upon trifles incapable of resistance. On the other hand, it must be allowed that exertion and violence supply some want of space. A rock wonderfully supported, or threatening to fall, acquires a greatness from its situation, which it has not in dimensions; so circumstanced, the size appears to be monstrous. A torrent has a consequence which a placid river of equal breadth cannot pretend to; and a tree, which would be inconsiderable in the natural soil, becomes important when it bursts forth from a rock.

Such circumstances should be always industriously sought for. It may be worth while to cut down several trees, in order to exhibit one apparently rooted in the stone. By the removal perhaps of only a little brushwood, the alarming disposition of a rock, strangely undermined, rivetted, or suspended, may be shown; and if there be any soil above its brow, some trees planted there, and impending over it, will make the object still more extraordinary. As to the streams, great alterations may generally be made in them; and therefore it is of use to ascertain the species proper to each scene, because it is in our power to enlarge or contract their dimensions, to accelerate or retard their rapidity, to form, increase, or take away obstructions, and always to improve, often to change, their characters.

Inhabitants furnish frequent opportunities of strengthening the appearances of force, by giving intimations of danger. A house placed on the edge of a precipice, any building on the pinnacle of a crag, makes that situation seem formidable, which might otherwise have been unnoticed. A steep, in itself not very remarkable, becomes alarming when a path is carried aslant up the side; a rail on the brow of a perpendicular fall shows that the height is frequented and dangerous; and a common foot bridge thrown over a cleft between rocks has a still stronger effect. In all these instances, the imagination immediately transports the spectator to the spot, and suggests the idea of looking down such a depth; in the last, that depth is a chasm, and the situation is directly over it.

The different species of rocks often meet in the same place, and compose a noble scene, which is not distinguished by any particular character; it is only when one eminently prevails that it deserves such a preference as to exclude every other. Sometimes a spot remarkable for nothing but its wildness is highly romantic; and when this wildness rises to fancy, when the most singular, the most opposite, forms and combinations are thrown together, then a mixture also of several characters adds to the number of nstances which there concur to display the inexhaustible variety of nature.

So much variety, so much fancy, are seldom found withn the same extent as in Dovedale. It is about two miles in ength, forming a deep, narrow, hollow valley; both the sides are of rock; and the Dove in its passage between them is perpetually changing its course, its motion, and appearance. It is never less than ten, nor so much as twenty yards wide, and generally about four feet deep, but transparent to the bottom, except when it is covered with a oam of the purest white, under waterfalls which are perectly lucid. These are very numerous, but very different. n some places they stretch straight across or aslant the tream; in others they are only partial, and the water eiher dashes against the stones and leaps over them, or pourng along a steep, rebounds upon those below; sometimes t rushes through the several openings between them, someimes it drops gently down, and at other times it is driven back by the obstruction, and turns into an eddy. In one particular spot, the valley, almost closing, leaves hardly a passage for the river, which, pent up and struggling for a vent, rages, and roars, and foams, till it has extricated tself from the confinement. In other parts, the stream, hough never languid, is often gentle; it flows round a ittle desert island, glides between bits of bulrushes, disperses itself amongst tufts of grass or of moss, bubbles about a water dock, or plays with the slender threads of aquatic plants which float upon the surface. The rocks all along he dale vary as often in their structure as the stream in ts motion. In one place, an extended surface gradually diminishes from a broad base almost to an edge; in anoher, a heavy top hanging forwards, overshadows all beneath; sometimes many different shapes are confusedly umbled together, and sometimes they are broken into lender sharp pinnacles, which are upright, often two or hree together, and often in more numerous clusters. On he one side of the dale they are universally bare, on the ther they are intermixed with wood; and the vast height f both the sides, with the narrowness of the interval beween them, produces a further variety. For whenever the un shines from behind the one, the form of it is distinctly nd completely cast upon the other; the rugged surface on which it falls diversifies the tints; and a strong reflected light often glares on the edge of the deepest shadow. The ocks never continue long in the same figure or situation, nd are very much separated from each other; sometimes hey form the sides of the valley, in precipices, in steeps, r in stages; sometimes they seem to rise in the bottom, nd lean back against the hill; and sometimes they stand ut quite detached, heaving up in cumbrous piles, or startng into conical shapes, like vast spars, a hundred feet in eight; some are firm and solid throughout; some are racked; and some, split and undermined, are wonderfully pheld by fragments apparently unequal to the weight they ustain. One is placed before, one over another, and one lls, at some distance behind, an interval between two. The hanges in their disposition are infinite; every step prouces some new combination; they are continually crossng, advancing, and retiring; the breadth of the valley is ever the same forty yards together. At the narrow pass which has been mentioned, the rocks almost meet at the op, and the sky is seen as through a chink between them; and just by this gloomy abyss is a wider opening, more light, more verdure, more cheerfulness than anywhere else in the dale. Nor are the forms and the situations of the rocks their only variety. Many of them are perforated by large natural cavities, some of which open to the sky, some terminate in dark recesses, and through some are to be seen several more uncouth arches and rude pillars, all detached, and retiring beyond each other, with the light shining in between them, till a rock far behind them closes the perspective. The noise of the cascades in the river echoes amongst them; the water may often be heard at the same time gurgling near and roaring at a distance; but no other sounds disturb the silence of the spot. The only trace of men is a blind path, but seldom and lightly trodden, by those whom curiosity leads to see the wonders they have been told of Dovedale. It seems indeed a fitter haunt for mere ideal beings; the whole has the air of enchantment. The perpetual shifting of the scenes, the quick transitions, the total changes; then the forms all around, grotesque as chance can cast, wild as nature can produce, and various as imagination can invent; the force which seems to have been exerted to place some of the rocks where they are now fixed immoveable, the magic by which others appear still to be suspended; the dark caverns, the illuminated recesses, the fleeting shadows, and the gleams of light glancing on the sides, or trembling on the stream; and the loneliness and the stillness of the place; all crowding together on the mind, almost realize the ideas which naturally present themselves in this region of romance and of fancy.

The solitude of such a scene is agreeable, on account of the endless entertainment which its variety affords, and in the contemplation of which both the eye and the mind are delighted to indulge. Marks of inhabitants and cultivation would disturb that solitude; and ornamental buildings are too artificial in a place so absolutely free from restraint. The only accompaniments proper for it are wood and water; and by these sometimes improvements may be made. Variety is the peculiar property of the spot, and every accession to it is a valuable acquisition. On the same principle, endeavours should be used, not only to multiply, but to aggravate differences, and to increase distinctions into contrasts; but the subject will impose a caution against attempting too much. Art must almost despair of improving a scene where nature seems to have exerted her inventive powers.

II. *Factitious Accompaniments.* These consist of fences, walks, roads, bridges, seats, and buildings. (See *Practical Treatise of Gardening*, p. 593, *et seqq.*)

1. The *fence*, where the place is large, becomes necessary; yet the eye dislikes constraint. Our ideas of liberty carry us beyond our own species; the imagination feels a dislike in seeing even the brute creation in a state of confinement. The birds wafting themselves from wood to grove are objects of delight; and the hare appears to enjoy a degree of happiness unknown to the barriered flock. Besides, a tall fence frequently hides from the sight objects the most pleasing; not only the flocks and herds themselves, but the surface they graze upon. These considerations have brought the unseen fence into general use.

This species of barrier, it must be allowed, incurs a degree of deception which can scarcely be warranted upon any other occasion. In this instance, however, it is a species of fraud which we observe in nature's practice. How often have we seen two distinct herds feeding to appearance in the same extended meadow, until, coming abruptly upon a deep sunk rivulet, or an unfordable river, we discover the deception.

Besides the sunk fence, another sort of unseen barrier may be made, though by no means equal to that, especially if near the eye. This is constructed of paling, painted of the invisible green. If the colour of the back ground

Principles.

were permanent, and that of the paint made exactly to correspond with it, the deception would at a distance be complete; but back grounds in general changing with the season, this kind of fence is the less eligible. Clumps and patches of woodiness scattered promiscuously on either side of an unseen winding fence assist very much in doing away the idea of constraint.

2. The *walk*, in extensive grounds, is as necessary as the fence. The beauties of the place are disclosed that they may be seen; and it is the office of the walk to lead the eye from view to view, in order that whilst the tone of health is preserved by the favourite exercise of nature, the mind may be thrown into unison by the harmony of the surrounding objects.

The direction of the walk must be guided by the points of view to which it leads, and the nature of the ground it passes over. It ought to be made subservient to the natural impediments, the ground, wood, and water, which fall in its way, without appearing to have any direction of its own. It can seldom run with propriety any distance in a straight line; a thing which rarely occurs in a natural walk. The paths of the negroes and Indians are always crooked; and those of the brute creation are similar.

3. The *road* may be a thing of necessity, as an approach to the mansion, or a matter of amusement only, as a drive or a ride, from which the grounds and the surrounding country may be seen to advantage. It should be the study of the artist to make the same road answer, as far as may be, the twofold purpose. The road and the walk are subject to the same rule of nature and use. The direction ought to be natural and easy, and adapted to the purpose intended. A road of necessity ought to be straighter than one of mere conveniency. In this, recreation is the predominant idea; in that, utility. But even in this the direct line may be dispensed with. The natural roads upon heaths and open downs, and the grassy glades and green roads across forests and extensive wastes, are proper subjects to be studied.

4. The *bridge* should never be visible where it is not wanted. A useless bridge is a deception; deceptions are frauds; and fraud is always hateful, unless when practised to avert some greater evil. A bridge without water is an absurdity; and half an one stuck up as an eye-trap is a paltry trick, which, though it may strike the stranger, cannot fail of disgusting when the fraud is found out. In low situations, and wherever water abounds, bridges become useful, and are therefore pleasing objects; they are looked for, and ought to appear, not as objects of ornament only, but likewise as matters of utility. The walk or the road therefore ought to be directed in such a manner as to cross the water at the point in which the bridge will appear to the greatest advantage.

In the construction of bridges, also, regard must be had to ornament and utility. A bridge is an artificial production, and as such it ought to appear. It ranks amongst the noblest of human inventions; the ship and the fortress alone excel it. Simplicity and firmness are the leading principles in its construction. Mr Wheatley's observation is just when he says, "the single wooden arch, now much in fashion, seems to me generally misapplied. Elevated without occasion so much above, it is totally detached from, the river; it is often seen straddling in the air, without a glimpse of water to account for it; and the ostentation of it as an ornamental object diverts all that train of ideas which its use as a communication might suggest." But we differ from this ingenious writer when he tells us that it is spoiled if adorned, and disfigured if only painted of any other than a dusky colour. In a rustic scene, where nature wears her own coarse garb, "the vulgar foot bridge of planks, only guarded on one hand by a common rail, and supported by a few ordinary piles," may be in character; but amidst a display of ornamented nature, a contrivance of that kind would appear mean and paltry, and would be an affectation of simplicity rather than the lovely attribute itself. In cultivated scenes, the bridge ought to receive the ornaments which the laws of architectural taste allow; and the more polished the situation, the higher should be the style and finishings.

5. *Seats* have a twofold use; they are useful as places of rest and conversation, and as guides to the points of view in which the beauties of the surrounding scene are disclosed. Every point of view should be marked with a seat; and, speaking generally, no seat ought to appear but in some favourable point of view. This rule may not be invariable, but it ought seldom to be deviated from. In the ruder scenes of neglected nature, the simple trunk, rough from the woodman's hands, and the butts or stools of rooted trees, without any other marks of tools upon them than those of the saw which severed them from their stems, are seats in character; and in romantic or recluse situations the cave or the grotto are admissible. But wherever human design has been executed upon the natural objects of the place, the seat and every other artificial accompaniment ought to be in unison; and whether the bench or the alcove be chosen, it ought to be formed and finished in such a manner as to unite with the wood, the lawn, and the walk, which lie around it. The colour of seats should likewise be suited to situations. Where uncultivated nature prevails, the natural brown of the wood itself ought not to be altered; but where the rural art presides, white or stone colour has a much better effect.

6. *Buildings* probably were first introduced into gardens merely for convenience, to afford refuge from a sudden shower, and shelter against the wind, or, at the most, to be seats for a party, or for retirement. They have since been converted into objects, and now the original use is too often forgotten in the greater purposes to which they are applied. They are considered as objects only; the inside is totally neglected, and a pompous edifice frequently wants a room barely comfortable. Sometimes the pride of making a lavish display to a visitor, without any regard to the owner's enjoyments, and sometimes too scrupulous an attention to the style of the structure, occasions a poverty and dulness within which deprive the buildings of part of their utility. But in a garden they ought to be considered both as beautiful objects and as agreeable retreats; if a character becomes them, it is that of the scene they belong to, not that of their primitive application. A Grecian temple or Gothic church may adorn spots where it would be affectation to preserve that solemnity within which is proper for places of devotion. They are not to be exact models, subjects only of curiosity or study; they are also seats; and such seats will be little frequented by the proprietor, his mind being generally indisposed to so much simplicity, and so much gloom, in the midst of gaiety, richness, and variety.

But though the interior of buildings should not be disregarded, it is by their exterior that they become objects; and sometimes by the one, sometimes by the other, and sometimes by both, they are entitled to be considered as characters. As objects, they are designed either to distinguish, or to break, or to adorn, the scenes to which they are applied.

The differences between one wood, one lawn, one piece of water, and another, are not always very apparent. The several parts of a garden would, therefore, often appear similar, if they were not distinguished by buildings; but these are so observable, so obvious at a glance, so easily retained in the memory, they mark the spots where they are placed with so much strength, they attract the relation of all around with so much power, that parts thus distinguished can never be confounded together. Yet it by no means follows that therefore every scene must have its edifice. The want of one is sometimes a variety; and other circumstances are often sufficiently characteristic. It is only when these too nearly agree that we must have recourse to buildings for differences. We can introduce, exhibit, or contrast them as we please. The most striking object is thereby made a mark of distinction, and the force of this first impression prevents our observing the points of resemblance.

The uniformity of a view may be broken by similar means, and on the same principle. When a wide heath, a dreary moor, or a continual plain, is in prospect, objects which catch the eye supplant the want of variety. None are so effectual for this purpose as buildings. Plantations or water can have no very sensible effect, unless they are large and numerous, and almost change the character of the scene; but a small single building diverts the attention at once from the sameness of the extent, which it breaks but does not divide, and diversifies without altering its nature. The design, however, must not be apparent. The merit of a cottage applied to this purpose, consists in its being free from the suspicion; and a few trees near it will both enlarge the object, and account for its position. Ruins are a hackneyed device, immediately detected, unless their style be singular, or their dimensions extraordinary. The semblance of an ancient British monument might be adapted to the same end, with little trouble, and great success. The materials might be brick, or even timber plastered over, if stone could not easily be procured. Whatever they were, the fallacy would not be discernible; it is an object to be seen at a distance, rude, and large, and in character agreeable to a wild open view. But no building ought to be introduced which may not in reality belong to such a situation; no Grecian temples, no Turkish mosques, no Egyptian obelisks or pyramids, none imported from foreign countries, and unusual in this. The apparent artifice would destroy an effect, which is so nice as to be weakened, if objects proper to produce it are displayed with too much ostentation; if they seem to be contrivances, not accidents, and the advantage of their position appear to be more laboured than natural.

But in a garden, where objects are intended only to adorn, every species of architecture may therefore be admitted, from the Grecian down to the Chinese; and the choice is so free, that the mischief most to be apprehended is an abuse of this latitude in the multiplicity of buildings. Few scenes can bear more than two or three; in some, a single one has a greater effect than any number; and a careless glimpse, here and there, of such as belong immediately to different parts, frequently enlivens the landscape with more spirit than those which are industriously shown. If the effect of a partial sight, or a distant view, were more attended to, many scenes might be filled, without being crowded; a greater number of buildings would be tolerated when they seemed to be casual, not forced; and the animation and richness of the objects might be attained without pretence or display.

Too fond an ostentation of buildings, even of those which are principal, is a common error; and when all has been done, they are not always shown to the greatest advantage. Though their symmetry and their beauties ought in general to be distinctly and fully seen, yet an oblique is sometimes better than a direct view; and they are often less agreeable objects when entire, than when a part is covered, or their extent is interrupted; when they are bosomed in wood, as well as backed by it, or appear between the stems of trees which rise before or above them. Thus thrown into perspective, thus grouped and accompanied, they may be as important as if they were quite exposed, and are frequently more picturesque and beautiful.

But a still greater advantage arises from this management in connecting them with the scene. They are considerable, and different from all around them; inclined therefore to separate from the rest; and yet sometimes still more detached by the pains taken to exhibit them. That very importance which is the cause of the distinction, ought to be a reason for guarding against the independence to which it is naturally prone, and by which an object which ought to be a part of the whole is reduced to a mere individual. An elevated is generally a noble situation. When it is a point or pinnacle, the structure may be a continuation of the ascent; and on many occasions, some parts of the building may descend lower than others, and multiply the appearances of connection. But an edifice in the midst of an extended ridge commonly seems naked alone, and imposed upon the brow, not joined to it. If wood, to accompany it, will not grow there, it had better be brought a little way down the declivity; and then all behind, above, and about it, are so many points of contact, by which it is incorporated into landscape.

Accompaniments are important to a building; but they lose much of their effect when they do not appear to be casual. A little mount just large enough for it, a small piece of water below, of no other use than to reflect it, and a plantation close behind, evidently placed there only to give it relief, are as artificial as the structure itself, and alienate it from the scene of nature into which it is introduced, and to which it ought to be reconciled. These appendages therefore should be so disposed, and so connected with the adjacent parts, as to answer other purposes, though applicable to this; that they may be bonds of union, not marks of difference, and that the situation may appear to have been chosen, not made, for the building.

In the choice of a situation, that which shows the building best ought generally to be preferred. Eminence, relief, and every other advantage which can be obtained, ought to be given to an object of so much consideration. They are for the most part desirable, sometimes necessary, and exceptionable only when, instead of rising out of the scene, they are forced into it, and a contrivance to procure them at any rate is avowed without any disguise. There are, however, occasions in which the most tempting advantages of situation must be waived; the general composition may forbid a building in one spot, or require it in another; at other times the interest of the particular group it belongs to may exact a sacrifice of the opportunities to exhibit its beauties and importance; and at all times the pretensions of every individual object must give way to the greater effect of the whole.

The same structure which adorns as an object, may also be expressive as a character. Where the former is not wanted, the latter may be desirable, or it may be weak for one purpose, and strong for the other; it may be grave or gay, magnificent or simple, and, according to its style, may or may not be agreeable to the place it is applied to. But mere consistency is not all the merit which buildings can claim; their characters are sometimes strong enough to determine, improve, or correct, that of the scene; and they are so conspicuous, and so distinguished, that whatever force they have is immediately and sensibly felt. They are fit therefore to make a first impression; and when a scene is but faintly characterized, they give at once a cast which spreads over the whole, and which the weaker parts concur to support, though perhaps they were not able to produce it.

Nor do they stop at fixing an uncertainty, or removing a doubt; they raise and enforce a character already marked. A temple adds dignity to the noblest, a cottage simplicity to the most rural, scenes; the lightness of a spire, the airiness of an open rotunda, the splendour of a continued colonnade, are less ornamental than expressive; others improve cheerfulness into gaiety, gloom into solemnity, and richness into profusion. A retired spot, which might have been passed unobserved, is noticed for its tranquillity as soon as it is appropriated by some structure to retreat; and the most unfrequented place seems less solitary than one which appears to have been the haunt of a single individual, or even of a sequestered family, and is marked by a lonely dwelling, or the remains of a deserted habitation.

The means are the same, the application of them only is different, when buildings are used to correct the character of the scene; to enliven its dulness, mitigate its gloom, or to check its extravagance, and, on a variety of occasions, to soften, to aggravate, or to counteract, particular circumstances attending it. But care must be taken that they do not contradict too strongly the prevailing idea. They may lessen the dreariness of a waste, but they cannot give it amenity; they may abate horrors, but they will never convert them into graces; they may make a tame scene agreeable, and even interesting, not romantic; or turn solemnity into cheerfulness, but not into gaiety. In these, and in many other instances, they correct the character, by giving it an inclination towards a better, which is not very different; but they can hardly alter it entirely, and when they are totally inconsistent with it, they are at the best nugatory.

The great effects which have been ascribed to buildings do not depend upon those trivial ornaments and appendages which are often too much relied on; such as the furniture of a hermitage, painted glass in a Gothic church, and sculpture about a Grecian temple; grotesque or bacchanalian figures to denote gaiety, and death's heads to signify melancholy. Such devices are only descriptive, not expressive, of character; and must not be substituted in the room of those superior properties, the want of which they acknowledge, but do not supply. They besides often require time to trace their meaning, and to see their application; but the peculiar excellence of buildings is, that their effects are instantaneous, and therefore the impressions they make are forcible. In order to produce such effects, the general style of the structure, and its position, are the principal considerations. Either of them will sometimes be strongly characteristic alone; united, their powers are very great; and both are so important, that if they do not concur, at least they must not contradict one another.

Every branch of architecture furnishes, on different occasions, objects proper for a garden; and there is no restraint on our selection, provided it be conformable to the style of the scene, proportioned to its extent, and agreeable to its character. The choice of situations is also perfectly free. A hermitage, indeed, must not be close to a road; but whether it be exposed to view on the side of a mountain, or concealed in the depth of a wood, is almost a matter of indifference; that it is at a distance from public resort is sufficient. A castle must not be sunk in a dell; but that it should stand on the utmost pinnacle of a hill, is not necessary; on a lower knoll, and backed by the rise, it may appear to greater advantage as an object, and be much more important to the general composition. Many buildings, which from their splendour best become an open exposure, will yet be sometimes not ill bestowed on a more sequestered spot, either to characterize or adorn it; and others, for which a solitary would in general be preferred to an eminent situation, may occasionally be objects in very conspicuous positions. A Grecian temple, from its peculiar taste and dignity, deserves every distinction; it may, however, in the depth of a wood, be so circumstanced that the want of those advantages to which it seems entitled will not be regretted. A happier situation cannot be devised, than that of the temple of Pan on the south lodge on Enfield Chase. It is of the usual oblong form, encompassed by a colonnade; in dimensions and in style it is equal to a most extensive landscape. And yet, by the antique and rustic air of its Doric columns without bases; by the chastity of its little ornaments, a crook, a pipe, and a scrip, and those only over the doors; and by the simplicity of the whole, both within and without; it is adapted with so much propriety to the thickets which conceal it from the view, that no one can wish it to be brought forward, who is sensible to the charms of the Arcadian scene which this building alone has created. On the other hand, a very spacious field, or sheep walk, will not be disgraced by a farm house, a cottage, or a Dutch barn; nor will they, though small and familiar, appear to be inconsiderable or insignificant objects. Numberless other instances might be adduced to prove the impossibility of restraining particular buildings to particular situations, upon any general principles: the variety in their forms is hardly greater than in their application. Only let not their uses be disguised, as is often absurdly attempted with the humbler kinds of buildings. A barn dressed up in the habit of a country church, or a farm house figuring away in the fierceness of a castle, are ridiculous deceptions. A landscape daubed upon a board, and a wooden steeple stuck up in a wood, are beneath contempt.

Temples, those favourite and most costly objects in gardens, too generally merit censure for their inutility, their profusion, or the impropriety of their purpose. Whether they be dedicated to Bacchus, Venus, Priapus, or any other demon of debauchery, they are in this age equally absurd. Architecture, in this part of its sphere, may more nobly, and with greater beauty and effect, be exercised upon a chapel, a mausoleum, a monument, judiciously disposed among the natural ornaments. Sir William Harbord has given us a model of the first kind, at Gunton in Norfolk: the parish church standing in his park, and being an old unsightly building, he had it taken down, and a beautiful temple, under the direction of the Adams, erected upon its site for the same sacred purpose. The mausoleum at Castle-Howard, in Yorkshire, the seat of the Earl of Carlisle, is a noble structure; and as an instance of the last sort, may be mentioned the temple of Concord and Victory at Stowe, erected to the memory of the great Lord Chatham and his glorious war; a beautiful monumental building, suited to the greatness of the occasion.

To the great variety above mentioned must be added, as Mr Wheatley observes, the many changes which may be made by the means of ruins. They are a class by themselves, beautiful as objects, expressive as characters, and peculiarly calculated to connect with appendages into elegant groups. They may be accommodated with ease to irregularity of ground, and their disorder is improved by it. They may be intimately blended with trees and thickets; and the interruption is an advantage; for imperfection and obscurity are their properties, and to carry the imagination to something greater than is seen is their effect. They may for any of these purposes be separated into detached pieces: contiguity is not necessary, nor even the appearance of it, if the relation be preserved; but straggling ruins have a bad effect when the several parts are equally considerable. There should be one large mass to raise an idea of greatness, to attract the others about it, and to be a common centre of union to all. The smaller pieces then mark the original dimensions of one extensive structure, and no longer appear to be the remains of several little buildings.

All remains excite an inquiry into the former state of the edifice, and fix the mind in a contemplation of the use it was applied to; besides the characters expressed by their style and position, they suggest ideas which would not arise from the buildings if entire. The purposes of many have ceased. An abbey, or a castle, if complete, can now be no more than a dwelling: the memory of the times, and of the manners to which they are adapted, is preserved only in history and in ruins; and certain sensations of regret, of veneration, or compassion, attend the recollection. Nor are these confined to the remains of buildings which are in disuse; those of an old mansion raise reflections on the domestic comforts once enjoyed, and the ancient hospitality which reigned there. Whatever building we see in decay, we naturally contrast its present with its former state, and delight to ruminate on the comparison. It is true that such effects properly belong to real ruins. They are, however, produced in a certain degree by those which are fictitious. The impressions are not so strong, but they are exactly similar; and the representation, though it does not present facts to the memory, yet suggests subjects to the imagination. But, in order to affect the fancy, the supposed original design should be clear, the use obvious, and the form easy to be traced. No fragments should be hazarded without precise meaning, and an evident connection; none should be perplexed in their construction, or uncertain as to their application. Conjectures about the form raise doubts about the existence of the ancient structure. The mind must not be allowed to hesitate; it must be hurried away from examining into the reality by the exactness and the force of the resemblance.

In the ruins of Tintern Abbey, the original construction of the church is perfectly marked; and it is principally from this circumstance that they are celebrated as a subject of curiosity and contemplation. The walls are almost entire; the roof only is fallen in, but most of the columns which divided the aisles are still standing. Of those which have dropped down, the bases remain, every one exactly in its place; and in the middle of the nave four lofty arches, which once supported the steeple, rise high in the air above all the rest, each reduced now to a narrow rim of stone, but completely preserving its form. The shapes even of the windows are little altered; but some of them are quite obscured, others partially shaded, by tufts of ivy; and those which are most clear are edged with its slender tendrils and lighter foliage, wreathing about the sides and the divisions. It winds round the pillars; it clings to the walls; and in one of the aisles clusters at the top in branches, so thick and so large as to darken the space below. The other aisles, and the great nave, are exposed to the sky. The floor is entirely overspread with turf; and to keep it clear from weeds and bushes is now its highest preservation. Monkish tombstones, and the monuments of benefactors long since forgotten, appear above the green sward. The bases of the pillars which have fallen rise out of it; and maimed effigies, and sculpture worn with age and weather, Gothic capitals, carved cornices, and various fragments, are scattered about, or lie in heaps piled up together. Other shattered pieces, though disjointed and mouldering, still occupy their original places; and a staircase much impaired, which led to a tower now no more, is suspended at a great height, uncovered and inaccessible. Nothing is perfect, but memorials of every part still subsist; all certain, but all in decay, and suggesting at once every idea which can occur in a seat of devotion, solitude, and desolation. Upon such models fictitious ruins should be formed; and if any parts are entirely lost, they should be such as the imagination can easily supply from those which are still remaining. Distinct traces of the building which is supposed to have existed are less liable to the suspicion of artifice, than an unmeaning heap of confusion. Precision is always satisfactory, but in the reality it is only agreeable; in the copy it is essential to the imitation.

A material circumstance to the truth of the imitation is, that the ruins should appear to be very old. The idea is besides interesting in itself. A monument of antiquity is never seen with indifference; and a semblance of age may be given to the representation by the hue of the materials, the growth of ivy and other plants, and cracks and fragments seemingly occasioned rather by decay than by destruction. An appendage evidently more modern than the principal structure will sometimes corroborate the effect. The shed of a cottager amidst the remains of a temple, is a contrast both to the former and to the present state of the building; and a tree flourishing among ruins shows the length of time they have lain neglected. No circumstance so forcibly marks the desolation of a spot once inhabited, as the prevalence of nature over it. *Campos ubi Troja fuit*, is a sentence which conveys a stronger idea of a city totally overthrown, than a description of its remains; but in a representation to the eye, some remains must appear; and then the perversion of them to an ordinary use, or an intermixture of a vigorous vegetation, intimates a settled despair of their restoration.

SECT. II.—PRINCIPLES OF SELECTION AND ARRANGEMENT IN THE SUBJECTS OF GARDENING.

1. *Of art.* In the lower classes of rural improvements, art should be seen as little as possible; and in the more negligent scenes of nature, every thing ought to appear as if it had been done by the general laws of nature, or had grown out of a series of fortuitous circumstances. But in the higher departments art cannot be hid; and the appearance of design ought not to be excluded. A human production cannot be made perfectly natural, and, held out as such, it becomes an imposition. Our art lies in endeavouring to adapt the productions of nature to human taste and perceptions; and if much art be used, do not attempt to hide it. Art seldom fails to please when executed in a masterly manner; nay, it is frequently the design and execution, more than the production itself, that strikes us. It is the artifice, not the design, which ought to be avoided. It is the labour, and not the art, which ought to be concealed. The rural artist ought therefore, upon every occasion, to endeavour to avoid labour; or, if indispensably necessary, to conceal it. No trace should be left to lead back the mind to the expensive toil. A mound raised, a mountain levelled, or a useless temple built, convey to the mind feelings equally disgusting.

2. *Picturesque beauty.* Though the aids of art are as essential to gardening as education is to manners, yet art may do too much. She ought to be considered as the handmaid, not as the mistress, of nature; and whether she be employed in carving a tree into the figure of an animal, or in shaping a view into the form of a picture, she is equally culpable. The nature of the place is sacred. Should this tend to landscape, from some principal point of view, assist nature and perfect it; provided this can be done without injuring the views from other points. But do not disfigure the natural features of the place; do not sacrifice its native beauties to the arbitrary laws of landscape painting. Nature indeed scarcely knows the thing mankind call a landscape. The landscape painter seldom or never finds it perfected to his hands; some addition or alteration is almost always wanted. Every man who has made his observations upon natural scenery knows that the misletoe of the oak occurs almost as often as a perfect natural landscape; and to attempt to make up artificial landscape upon every occasion is unnatural and absurd.

If, indeed, the eye were fixed in one point, the trees could be raised to their full height at command, and the sun be made to stand still; the rural artist might work by the rules of light and shade, and compose his landscape by the painter's law. But whilst the sun continues to pour forth its light impartially, and the trees to rise in slow progression, it would be ridiculous to attempt it. Let him rather seek out, imitate, and associate, such striking passages in nature as are immediately applicable to the place to be improved; let him, in short, "be various, wild, and free, as Nature's self;" instead of sacrificing the natural beauties of the place to one formal landscape, let every step disclose fresh charms unsought for.

3. *Of character.* Character is very reconcilable with beauty; and, even when independent of it, has attracted so much regard as to occasion several frivolous attempts to produce it. Statues, inscriptions, and even paintings, history and mythology, and a variety of devices, have been introduced for this purpose. The heathen deities and heroes have therefore had their several places assigned to them in the woods and lawns of a garden; natural cascades have been disfigured with river gods, and columns erected only to receive quotations; the compartiments of a summer-house have been filled with pictures of gambols and revels as significant of gaiety; the cypress, because it was once used in funerals, has been thought peculiarly adapted to melancholy; and the decorations, the furniture, and the environs of a building, have been crowded with puerilities under pretence of propriety. All these devices are rather emblematical than expressive; they may be ingenious contrivances, and recal absent ideas to the recollection, but they make no immediate impression; for they must be examined, compared, perhaps explained, before the whole design of them is well understood. And though an allusion to a favourite or well-known subject of history, of poetry, or of tradition, may now and then animate or dignify a scene; yet as the subject does not naturally belong to a garden, the allusion should not be principal. It should seem to have been suggested by the scene; a transitory image, which irresistibly occurred, not sought for, not laboured, and should have the force of a metaphor, free from the detail of an allegory.

Another species of character arises from direct imitation, when a scene or an object, which has been celebrated in description, or is familiar in idea, is represented in a garden. Artificial ruins, lakes, and rivers, fall under this denomination. The air of a seat extended to a distance, and scenes calculated to raise ideas of Arcadian elegance or of rural simplicity, with many more which have been occasionally mentioned, or will obviously occur, may be ranked in this class. They are all representations. But the materials, the dimensions, and other circumstances, being the same in the copy and the original, their effects are similar in both; and if not equally strong, the defect is not in the resemblance; but the consciousness of an imitation checks that train of thought which the appearance naturally suggests. Yet an over-anxious solicitude to disguise the fallacy is often the means of exposing it. Too many points of likeness sometimes hurt the deception; they seem studied and forced; and the affectation of resemblance destroys the supposition of a reality. A hermitage is the habitation of a recluse; it should be distinguished by its solitude and its simplicity; but if it is filled with crucifixes, hour-glasses, beads, and every other trinket which can be thought of, the attention is diverted from enjoying the retreat to examining the particulars. All the collateral circumstances which agree with a character seldom meet in one subject; and when they are industriously brought together, though each be natural, the collection is artificial.

But the art of gardening aspires to more than imitation. It can create original characters, and give expressions to the several scenes superior to any they can receive from allusions. Certain properties, and certain dispositions, of the objects of nature, are adapted to excite particular ideas and sensations; many of them have been occasionally mentioned, and all are very well known. They require no discernment, examination, or discussion, but are obvious at a glance, and instantaneously distinguished by our feelings. Beauty alone is not so engaging as this species of character. The impressions it makes are more transient and less interesting; for it aims only at delighting the eye, but the other affects our sensibility. An assemblage of the most elegant forms in the happiest situations is to a degree indiscriminate, if they have not been selected and arranged with a design to produce certain expressions; an air of magnificence or of simplicity, of cheerfulness, tranquillity, or some other general character, ought to pervade the whole; and objects pleasing in themselves, if they contradict that character, should therefore be excluded. Those which are only indifferent must sometimes make room for such as are more significant; many will often be introduced for no other merit than their expression; and some, which are in general rather disagreeable, may occasionally be recommended by it.

The power of such characters is not confined to the ideas which the objects immediately suggest; for these are connected with others which insensibly lead to subjects far distant perhaps from the original thought, and related to it only by a similitude in the sensations they excite. In a prospect enriched and enlivened with inhabitants and cultivation, the attention is caught at first by the circumstances which are gayest in their season, the bloom of an orchard, the festivity of a hay field, and the carols of harvest home; but the cheerfulness which these infuse into the mind expands afterwards to other objects than those immediately presented to the eye; and we are thereby disposed to receive, and delighted to pursue, a variety of pleasing ideas, and every benevolent feeling. At the sight of a ruin, reflections on the change, the decay, and the desolation before us, naturally occur; and they introduce a long succession of others, all tinctured with that melancholy which these have inspired; or if the monument revive the memory of former times, we do not stop at the simple fact which it records, but recollect many more coeval circumstances, which we see, not perhaps as they were, but as they are come down to us, venerable with age, and magnified by fame. Even without the assistance of buildings or other adventitious circumstances, nature alone furnishes the materials for scenes which may be adapted to almost every kind of expression. Their operation is general, and their consequences are infinite. The mind is elevated, depressed, or composed, as gaiety, gloom, or tranquillity prevails in the scene; and we soon lose sight of the means by which the character is formed; we forget the particular objects it presents, and, giving way to their effects, without recurring to the cause, we follow the track they have begun, to any extent which the disposition they accord with will allow. It suffices that the scenes of nature have a power to affect our imagination and our sensibility; for such is the constitution of the human mind, that if once it is agitated, the emotion spreads far beyond the occasion. When the passions are roused, their course is unrestrained; when the fancy is on the wing, its flight is unbounded; and, quitting the inanimate objects which first gave them the spring, we may be led by thought above thought, widely differing in degree, but still corresponding in character, till we rise from familiar subjects up to the sublimest conceptions, and are wrapt in the contemplation of whatever is great or beautiful which we see in nature, feel in man, or attribute to divinity.

4. *General arrangement.* Notwithstanding the nature

of the place, as already observed, ought not to be sacrificed to the mansion, the house must ever be allowed to be a principal in the composition. It ought, in fact, to be considered as the centre of the system; and the rays of art, like those of the sun, should grow fainter as they recede from the centre. The house itself being entirely a work of art, its immediate environs should be highly finished; but as the distance increases, the appearance of design should gradually diminish, until nature and fortuitousness have full possession of the scene.

In general, the approach should be to the back front, which, in suitable situations, ought to lie open to the pasture-grounds. On the sides more highly ornamented, a well-kept gravel walk may embrace the walls; to this the shaven lawn and shrubbery succeed; next, the grounds closely pastured; and, lastly, the surrounding country, which ought not to be considered as out of the artist's reach. For his art consists not more in decorating particular spots, than in endeavouring to render the whole face of nature delightful.

Another reason for this mode of arrangement is, that objects immediately under the eye are seen more distinctly than those at a distance, and ought to be such as are pleasing in the detail. The beauties of a flower can be discerned on a near view only; whilst at a distance a roughet of coppice wood, and the most elegant arrangement of flowering shrubs, have the same effect. The most rational entertainment the human mind is capable of receiving is that of observing the operations of nature. The foliation of a leaf, the blowing of flowers, and the maturation of fruits, are amongst the most delightful subjects that a contemplative mind can be employed in. These processes of nature are slow; and, except the object fall spontaneously under the eye of the observer, the inconveniences of visiting it in a remote part so far interfere with the more important employments of life as to blunt, if not destroy, the enjoyment. This is a strong argument in favour of shrubs and flowers being planted under or near our windows, especially those from whence they may be viewed during the hours of leisure and tranquillity.

Execution of the General Subjects.

Further, the vegetable creation being subject to the animal, the shrub may be cropped, or the flower trodden down, in its day of beauty. If therefore we wish to converse with nature in private, intruders must be kept off, and the shrubbery be severed from the ground, yet not in such a manner as to drive away the pasturing stock from our sight. For this reason, the shaven lawn ought not to be too extensive, and the fence which encloses it should be such as will not interrupt the view. But whether it be seen or unseen, suspected or unsuspected, is a matter of no great import. Its utility in protecting the shrubs and flowers; in keeping the horns of the cattle from the window, and the feet of the sheep from the gravel and broken ground; in preserving that neatness on the outside, which ought to correspond with the finishings and furniture within; render it of sufficient importance to become even a part of the ornament.

III.—EXECUTION OF THE GENERAL SUBJECTS.

Improvements in general may be classed under the heads of the *Hunting-Box*, the *Ornamented Cottage*, the *Villa*, and the *Principal Residence*.

But before any step can be taken towards the execution of the design, be it large or small, a map or plan of the place, exactly as it lies in its unimproved state, should be made, with a corresponding sketch upon which to mark the intended improvements. Not a hovel nor a twig should be touched, until the artist has studied maturely the natural abilities of the place, and has decidedly fixed in his mind, and finally settled on his plan, the proposed alterations; and even then, let him temper his daring with caution.

1. *Of Improvements adapted to a Hunting-Box.*

Here art has little to do. Hunting may be called the amusement of nature; and the place appropriated to it ought to be no further altered from its natural state than decency and conveniency require. With men who live in the present age of refinement, a want of decency is a want of sense.

The style throughout should be masculine. If shrubs be required, they should be of the hardier sorts; the box, the holly, the laurustinus. The trees should be the oak and the beech, which give in autumn an agreeable variety of foliage, and anticipate as it were the season of diversion. A suite of paddocks should be seen from the house; and if a view of distant covers can be caught, the back-ground will be complete. The stable, the kennel, and the leaping-bar, are the factitious accompaniments, in the construction of which simplicity and convenience should prevail.

2. *Of the Style of an Ornamented Cottage.*

Neatness and simplicity ought to mark the style of this rational retreat. Ostentation and show should be cautiously avoided; even elegance should not be attempted, though it may not be hid, if it offer itself spontaneously. Nothing, however, should appear vulgar, nor should simplicity be pared down to baldness; every thing whimsical or expensive ought to be studiously avoided; chasteness and frugality should appear in every part. If a taste for botany lead to a collection of native shrubs and flowers, a shrubbery will be requisite; but in this every thing should be native. A gaudy exotic ought not to be admitted; nor should the lawn be kept close shaven; its flowers should be permitted to blow, and the herbage, when mown, ought to be carried off, and applied to some useful purpose. In the artificial accompaniments, ornament must be subordinate, utility must preside. The buildings, if any appear, should be those in actual use in rural economics. If the hovel be wanted, let it appear; and, as a side-screen, the barn and rick-yard are admissible, whilst the dove-house and poultry-yard may enter more freely into the composition. In a word, the ornamented cottage ought to exhibit cultivated nature in the first stage of refinement. It ranks next above the farm house. The plain garb of rusticity may be set off to advantage; but the studied dress of the artist ought not to appear. That becoming neatness, and those domestic conveniences, which render the rural life agreeable to a cultivated mind, are all that should be aimed at.

3. *Of the Embellishment of a Villa.*

This demands a style very different from the preceding. It ought to be elegant, rich, or grand, according to the style of the house itself, and the state of the surrounding country; the principal business of the artist being to connect these two in such a manner that the one shall not appear naked or flaring, nor the other desolate and inhospitable. If the house be stately, and the adjacent country rich and highly cultivated, a shrubbery may intervene, in which art may show her utmost skill. Here the artist may even be permitted to play at landscapes; for a place of this kind being supposed to be small, the purpose principally ornamental, and the point of view probably con-

Execution of the General Subjects.

fined simply to the house, side-screens may be formed, and a fore-ground laid out suitable to the best distance that can be caught. If buildings or other artificial ornaments abound in the offscape, so as to mark it strongly, they ought also to appear more or less in the fore-ground; if the distance abound with wood, the fore-ground should be thickened, lest baldness should offend; if open and naked, elegance rather than richness ought to be studied, lest heaviness should appear.

It is far from being any part of our plan to cavil unnecessarily at artists, whether living or dead; we cannot, however, refrain from expressing a concern for the almost total neglect of the principles here in ornamenting the vicinages of villas. It is to be regretted that in the present practice these principles seem to be generally lost sight of. Without any regard to uniting the house with the adjacent country, and indeed seemingly without any regard whatever to the offscape, one invariable plan of embellishment prevails, namely, that of stripping the fore-ground entirely naked, or nearly so, and surrounding it with a wavy border of shrubs and a gravel walk; leaving the area, whether large or small, one naked sheet of green sward.

In small confined spots this plan may be eligible. But a simple border round a large unbroken lawn only serves to show what more is wanted. Simplicity in general is pleasing; but even simplicity may be carried to an extreme, so as to convey no other idea than that of poverty and baldness. Besides, how often do we see in natural scenery the holly and the fox-glove flourishing at the foot of an oak, and the primrose and the campion adding charms to the hawthorn scattered over the pastured lawn? And we conceive that single trees footed with evergreens and native flowers, and clumps as well as borders of shrubs, are admissible in ornamental as well as in natural scenery.

4. *Of the Principal Residence.*

Here the whole art centres, and the artist has full scope for a display of taste and genius. He has an extent of country under his eye, and will endeavour to make the most of what nature and accident have spread before him. Round a principal residence a gentleman may be supposed to have some considerable estate, and it is not a shrubbery and a ground only which fall under the consideration of the artist; he ought to endeavour to disclose to the view, either from the house or some other point, as much as he conveniently can of the adjacent estate. The love of possession is deeply planted in every man's breast, and places should bow to the gratification of their owners. To curtail the view by an artificial side-screen, or any other unnatural machinery, so as to deprive a man of the satisfaction of overlooking his own estate, is an absurdity which no artist ought to be permitted to be guilty of. It is very different, however, where the property of another intrudes upon the eye. Here the view may, with some colour of propriety, be bounded by a woody screen. The grounds, however, by a proper management, may be made independent of whatever is external; and though prospects are nowhere more delightful than from a point of view which is also a beautiful spot, yet if in the environs of such a garden they should be wanting, the elegant, picturesque, and various scenes within itself, almost supply the deficiency.

This is the character of the gardens at Stowe;[1] for there the views in the country are only circumstances subordinate to the scenes; and the principal advantage of the situation is the variety of the ground within the enclosure. The house stands on the brow of a gentle ascent; and part of the gardens lie on the declivity, and spread over the bottom beyond it. This eminence is separated by a broad winding valley from another which is higher and steeper; and the descents of both are broken by large dips and hollows, sloping down the sides of the hills. The whole space is divided into a number of scenes, each distinguished with taste and fancy; and the changes are so frequent, so sudden, and complete, the transitions so artfully conducted, that the same ideas are never continued or repeated to satiety.

These gardens were begun when regularity was in fashion; and the original boundary is still preserved, on account of its magnificence; for round the whole circuit of between three and four miles is carried a very broad gravel walk, planted with rows of trees, and open either to the park or the country; a deep sunk fence attends it all the way, and comprehends a space of near four hundred acres. But in the interior scenes of the garden few traces of regularity appear; and where it yet remains in the plantations, it is generally disguised. Every symptom almost of formality is obliterated from the ground; and an octagon basin in the bottom is now converted into an irregular piece of water, which receives on one hand two beautiful streams, and falls on the other down a cascade into a lake.

In the front of the house is a considerable lawn, open to the water, beyond which are two elegant Doric pavilions, placed in the boundary of the garden, but not marking it, though they correspond to each other; for still farther back, on the brow of some rising grounds without the enclosure, stands a noble Corinthian arch, by which the principal approach is conducted, and from which all the gardens are seen reclining back against their hills. They are rich with plantations, full of objects, and, lying on both sides of the house almost equally, every part is within a moderate distance, notwithstanding the extent of the whole.

On the right of the lawn, but concealed from the house, is a perfect garden scene, called the *queen's amphitheatre*, where art is avowed, though formality is avoided. The fore-ground is scooped into a gentle hollow. The plantations on the sides, though but just rescued from regularity, yet in style are contrasted to each other. They are on one hand chiefly thickets, standing out from a wood; on the other, they are open groves, through which a glimpse of the water is visible. At the end of the hollow, on a little knoll, quite detached from all appendages, is placed an open Ionic rotunda. Beyond it a large lawn slopes across the view; a pyramid stands on the brow; the queen's pillar in a recess on the descent; and all the three buildings, being evidently intended for ornament alone, are peculiarly adapted to a garden scene. Yet their number does not render it gay. The dusky hue of the pyramid, the retired situation of the queen's pillar, and the solitary appearance of the rotunda, give it an air of gravity. It is encompassed with wood, and all the external views are excluded; even the opening into the lawn is but an opening into an enclosure.

At the king's pillar, very near to this, is another lovely spot, which is small, but not confined; for no termination appears; the ground one way, the water another, retire under the trees out of sight, but nowhere meet with a boundary. The view is first over some very broken ground, thinly and irregularly planted; then between two beautiful clumps which feather down to the bottom; and, afterwards across a glade, and through a little grove beyond it, to that part of the lake where the thickets, close upon the brink, spread a tranquillity over the surface, in which the

---

Execution of the General Subjects.

shadows are reflected. Nothing is admitted to disturb that quiet. No building obtrudes; for objects to fix the eye are needless in a scene which may be comprehended at a glance, and none would suit the pastoral idea it inspires, of elegance too refined for a cottage, and of simplicity too pure for any other edifice.

The situation of the rotunda promises a prospect more enlarged; and in fact most of the objects on this side of the garden are there visible. But they want both connection and contrast; each belongs peculiarly to some other spot. They are all blended together in this without meaning, and are rather shown on a map than formed into a picture. The water only is capital; a broad expanse of it is so near as to be seen under the little groups on the bank without interruption. Beyond it is a wood, which in one place leaves the lake, to run up behind a beautiful building, of three pavilions, joined by arcades, all of the Ionic order. It is called *Kent's Building*. And never was a design more happily conceived. It seems to be characteristically proper for a garden; it is elegant, varied, and purely ornamental; it directly fronts the rotunda, and a narrow rim of the country appears above the trees beyond it. But the effect even of this noble object is fainter here than at other points; its position is not the most advantageous; and it is but one amongst many other buildings, none of which are principal.

The scene at the temple of Bacchus is in character directly the reverse of that about the rotunda, though the space and the objects are nearly the same in both; but in this all the parts concur to form one whole. The ground from every side shelves gradually towards the lake; the plantations on the further bank open to show Kent's building, rise from the water's edge towards the knoll on which it stands, and close again behind it. That elegant structure, inclined a little from a front view, becomes more beautiful by being thrown into perspective, and, though at a greater distance, is more important than before, because it is alone in the view; for the queen's pillar and the rotunda are removed far aside, and every other circumstance refers to this interesting object. The water attracts, the ground and the plantations direct, the eye thither; and the country does not just glimmer in the offscape, but is close and eminent above the wood, and connected by clumps with the garden. The scene altogether is a most animated landscape; and the splendour of the building, the reflection in the lake, the transparency of the water, and picturesque beauty of its form, diversified by little groups on the brink, while on the broadest expanse no more trees cast their shadows than are sufficient to vary the tints of the surface; all these circumstances, vying in lustre with each other, and uniting in the point to which every part of the scene is related, diffuse a peculiar brilliancy over the whole composition.

The view from Kent's building is very different from those which have been hitherto described. They are all directed down the declivity of the lawn. This rises up the ascent. The eminence being crowned with lofty wood, becomes thereby more considerable; and the hillocks into which the general fall is broken, sloping farther out this way than any other, they also acquire an importance which they had not before; that particularly on which the rotunda is placed seems here to be a profound situation; and the structure appears to be properly adapted to so open an exposure. The temple of Bacchus, on the contrary, which commands such an illustrious view, is itself a retired object, close under the covert. The wood rising on the brow, and descending down one side of the hill, is shown to be deep; is high, and seems to be higher than it is. The lawn too is extensive; and part of the boundary being concealed, it suggests the idea of still greater extent. A small portion only of the lake indeed is visible; but it is not here an object. It is a part of the spot; and neither termination being in sight, it has no diminutive appearance. If more water had been admitted, it might have hurt the character of the place, which is sober and temperate; neither solemn nor gay; great and simple, but elegant; above rusticity, yet free from ostentation.

These are the principal scenes on one side of the gardens. On the other, close to the lawn before the house, is the winding valley above mentioned, the lower part of which is assigned to the Elysian fields. These are watered by a lovely rivulet, and very lightsome and airy, so thinly are the trees scattered about them; they are open at one end to more water and a larger glade, and the rest of the boundary is frequently broken to let in objects afar off, which appear still more distant from the manner of showing them. The entrance is under a Doric arch, which coincides with an opening among the trees, and forms a kind of vista, through which a Pembroke bridge just below, and a lodge built like a castle in the park, are seen in a beautiful perspective. That bridge is at one extremity of the gardens, the queen's pillar is at another, yet both are visible from the same station in the Elysian fields; and all these external objects are unaffectedly introduced, divested of their own appurtenances, and combined with others which belong to the spot. The temple of Friendship is also in sight, just without the place; and within it are the temples of ancient Virtue and of the British worthies; the one in an elevated situation, the other low down in the valley, and near to the water. Both are decorated with the effigies of those who have been most distinguished for military, civil, or literary merit; and near to the former stands a rostral column, sacred to the memory of Captain Grenville, who fell in an action at sea. By placing here the meed of valour, and by filling these fields with the representations of those who have deserved best of mankind, the character intended to be given to the spot is justly and poetically expressed; and the number of the images which are presented or excited perfectly correspond with it. Solitude was never reckoned amongst the charms of Elysium; it has been always pictured as the mansion of delight and of joy; and in this imitation, every circumstance accords with that established idea. The vivacity of the stream which flows through the vale; the glimpses of another approaching to join it; the sprightly verdure of the green sward, and every bust of the British worthies, reflected in the water; the variety of the trees, the lightness of the greens, their disposition, all of them distinct objects, and dispersed over gentle inequalities of the ground; together with a multiplicity of objects both within and without, which embellish and enliven the scene; give it a gaiety which the imagination can hardly conceive, or the heart wish to be exceeded.

Close by this spot, and a perfect contrast to it, is the alder grove; a deep recess in the midst of a shade, which the blaze of noon cannot brighten. The water seems to be a stagnated pool, eating into its banks, and of a peculiar colour, not dirty, but clouded, and dimly reflecting the dun hue of the horse-chestnuts and alders which press upon the brink; the stems of the latter, rising in clusters from the same root, bear one another down, and slant over the water. Misshapen elms and ragged firs are frequent in the wood which encompasses the hollow; the trunks of dead trees are left standing amongst them; and the uncouth sumach, and the yew, with elder, nut, and holly, compose the underwood. Some limes and laurels are intermixed, but they are not many; the wood is in general of the darkest greens; and the foliage is thickened with ivy, which not only twines up the trees, but creeps also over the falls of the ground. These are steep and abrupt. The gravel-walk is covered with moss; and a

Execution of the General Subjects.

grotto at the end, faced with broken flints and pebbles, preserves, in the simplicity of its materials, and the duskiness of its colour, all the character of its situation. Two little rotundas near it were better away; one building is sufficient for such a scene of solitude as this, in which more circumstances of gloom concur than were perhaps ever collected together.

Immediately above the alder grove is the principal eminence in the gardens. It is divided by a great dip into two pinnacles, upon one of which is a large Gothic building. The space before this structure is an extensive lawn. The ground on one side falls immediately into the dip; and the trees which border the lawn sinking with the ground, the house rises above them, and fills the interval. The vast pile seems to be still larger than it is, for it is thrown into perspective, and between and above the heads of the trees, the upper story, the porticoes, the turrets, and balustrades, and all the slated roofs, appear in a noble confusion. On the other side of the Gothic building, the ground slopes down a long-continued declivity into a bottom, which seems to be perfectly irriguous. Divers streams wander about it in several directions. The conflux of that which runs from the Elysian fields with another below it is full in sight; and a plain wooden bridge thrown over the latter, and evidently designed for a passage, imposes an air of reality on the river. Beyond it is one of the Doric porticoes which front the house; but now it is alone; it stands on a little bank above the water, and is seen under some trees at a distance before it. Thus grouped, and thus accompanied, it is a happy incident, concurring with many other circumstances to distinguish this landscape by a character of cheerfulness and amenity.

From the Gothic building a broad walk leads to the Grecian valley, which is a scene of more grandeur than any in the gardens. It enters them from the park, spreading at first to a considerable breadth, then winds, grows narrower, but deeper, and loses itself at last in a thicket, behind some lofty elms, which interrupt the sight of the termination. Lovely woods and groves hang all the way on the declivities; and the open space is broken by detached trees, which, near the park, are cautiously and sparingly introduced, lest the breadth should be contracted by them; but as the valley sinks, they advance more boldly down the sides, stretch across or along the bottom, and cluster at times into groups and forms, which multiply the varieties of the larger plantations. These are sometimes close coverts, and sometimes open groves. The trees rise in one upon high stems, and feather down to the bottom in another; and between them are short openings into the park or the gardens. In the midst of the scene, just at the bend of the valley, and commanding it on both sides, upon a large, easy, natural rise, is placed the temple of Concord and Victory; at one place its majestic front of six Ionic columns, supporting a pediment filled with bas relief, and the points of it crowned with statues, faces the view; at another, the beautiful colonnade, on the side, of ten lofty pillars, retires in perspective. It is seen from every part; and impressing its own character of dignity on all around, it spreads an awe over the whole. But no gloom, no melancholy, attends it. The sensations it excites are rather placid, but full of respect, admiration, and solemnity. No water appears to enliven, no distant prospect to enrich, the view; the parts of the scene are large, the idea of it sublime, and the execution happy; it is independent of all adventitious circumstances, and relies on itself for its greatness.

The scenes which have been described are such as are most remarkable for beauty or character, but the gardens contain many more; and even the objects in these, by their several combinations, produce very different effects, within the distance sometimes of a few paces, from the unevenness of the ground, the variety of the plantations, and the number of the buildings. The multiplicity of the last has indeed been often urged as an objection to Stowe; and certainly, when all are seen by a stranger in two or three hours, twenty or thirty capital structures, mixed with others of inferior note, do seem too many. But the growth of the wood every day weakens the objection, by concealing them one from the other. Each belongs to a distinct scene; and if they are considered separately, at different times, and at leisure, it may be difficult to determine which to take away. Yet still it must be acknowledged that their frequency destroys all ideas of silence and retirement. Magnificence and splendour are the characteristics of Stowe. It is like one of those places celebrated in antiquity, which were devoted to the purposes of religion, and filled with sacred groves, hallowed fountains, and temples dedicated to several deities; the resort of distant nations, and the object of veneration to half the heathen world. This pomp is, at Stowe, blended with beauty; and the place is equally distinguished by its amenity and its grandeur.

In the midst of so much embellishment as may be introduced into this species of garden, a plain field or a sheep-walk is sometimes an agreeable relief; and even wilder scenes may occasionally be admitted. These indeed are not properly parts of a garden, but they may be comprehended within the verge of it; and the proximity to the more ornamented scenes is at least a convenience, that the transition from the one to the other may be easy, and the change always in our option. For though a spot in the highest state of improvement be a necessary appendage to a seat, yet, in a place which is perfect, other characters will not be wanting. If they cannot be had on a large scale, they are acceptable on a smaller; and so many circumstances are common to all, that they might often be intermixed; they may always border on each other.

But on this head it would be in vain to attempt to lay down particular rules. Different places are marked by sets of features as different from each other as are those in men's faces. Much must be left to the skill and taste of the artist; and let these be what they may, nothing but mature study of the natural abilities of the particular place to be improved can render him equal to the execution, so as to make the most of the materials that are placed before him. Some few general rules may nevertheless be laid down. The approach ought to be conducted in such a manner that the striking features of the place shall burst upon the view at once. No trick, however, should be made use of. All should appear to fall in naturally. In leading towards the house, its direction should not be fully in front, not exactly at an angle, but should pass obliquely upon the house and its accompaniments, so that their position with respect to each other, as well as the perspective appearance of the house itself, may vary at every step; and having shown the front and the principal wing, or other accompaniment, to advantage, the approach should wind to the back front, which, as has been already observed, ought to lie open to the park or pastured grounds.

The improvements, and the rooms from which they are to be seen, should be in unison. Thus, the view from the drawing-room should be highly embellished, to correspond with the beauty and elegance within. Every thing here should be feminine, elegant, beautiful, such as attunes the mind to politeness and lively conversation. The breakfasting room should have more masculine objects in view, wood, water, and an extended country for the eye to roam over; such as allures us imperceptibly to the ride or the chase. The eating and banqueting rooms need no exterior allurements.

Execution of the General Subjects.

There is a harmony in taste as well as in music. Variety, and even wildness upon some occasions, may be admitted; but discord cannot be allowed. If, therefore, a place be so circumstanced as to consist of properties totally irreconcilable, the parts ought, if possible, to be separated in such a manner that, like the air and the recitative, the adagio and the allegro, in music, they may set off each other's charms by the contrast. These observations may be illustrated by Mr Wheatley's description and proposed improvement of Persefield, near Chepstow, in Monmouthshire; a place upon which nature has lavished her favours, and which has been spoken of by Mr Gilpin, and other writers, in the most flattering terms.

Persefield is situated upon the banks of the river Wye, which divides Gloucestershire and Monmouthshire, and which was formerly the boundary between England and Wales. The general tendency of the river is from north to south; but about Persefield it describes by a winding course the letter S somewhat compressed. The grounds of Persefield are lifted high above the bed of the river, shelving, and form the brink of a lofty and steep precipice towards the south-west. The lower limb of the curvature is filled with Perse-wood, which makes a part of Persefield; but it is an impenetrable thicket of coppice wood, which dips to the south-east down to the water's edge, and, seen from the top of the opposite rock, has a good effect. The upper limb receives the farms of Llancot, rich and highly cultivated, broken into enclosures, and scattered with groups and single trees; two well-looking farm houses in the centre, and a neat white chapel on one side, forming altogether a lovely little paradisaical spot. The lowliness of its situation stamps it with an air of meekness and humility; and the natural barriers which surround it add that of peacefulness and security. The picturesque farms do not form a low flat bottom, subject to be overflowed by the river; but take the form of a gorget, rising fullest in the middle, and falling on every side gently to the brink of the Wye; except on the east side, where the top of the gorget leans in an easy manner against a range of perpendicular rock, as if to show its disk with advantage to the walks of Persefield

This rock stretches across what may be called the *Isthmus*, leaving only a narrow pass down into the fields of Llancot, and joins the principal range of rocks at the lower bend of the river. To the north, at the head of the latter, stands an immense rock, or rather a pile of immense rocks heaped one above another, called *Windcliff;* the top of which is elevated as much above the grounds of Persefield as those are above the fields of Llancot. These several rocks, with the wooded precipices on the side of Persefield, form a circular enclosure, about a mile in diameter, including Perse-wood, Llancot, the Wye, and a small meadow lying at the foot of Windcliff.

The grounds are divided into the upper and lower lawn by the approach to the house; a small irregular building, standing near the brink of the precipice, but facing down the lower lawn, a beautiful ground, falling "precipitately every way into a valley which shelves down in the middle," and is scattered with groups and single trees in an excellent style. The view from the house is soft, rich, and beautifully picturesque; the lawn and woods of Persefield, and the opposite banks of the river; the Wye, near its mouth, winding through meadows green as emerald, in a manner peculiarly graceful; the Severn, here very broad, backed by the wooded and highly cultivated hills of Gloucestershire, Wiltshire, and Somersetshire. Not one rock enters into the composition. The whole view consists of an elegant arrangement of lawn, wood, and water. The upper lawn is a less beautiful ground, and the view from it, though it command the "cultivated hills and rich valleys of Monmouthshire," bounded by the Severn, and backed by the Mendip Hills, is much inferior to that from the house. To give variety to the views from Persefield, to disclose the native grandeur which surrounds it, and to set off its more striking features to advantage, walks have been cut through the woods and on the face of the precipice which border the grounds to the south and east. The first point of view is marked by an alcove, from which are seen the bridge and the town of Chepstow, with its castle situated in a remarkable manner on the very brink of a perpendicular rock washed by the Wye; and beyond these the Severn shows a small portion of its silvery surface. Proceeding a little farther along the walk, a view is caught which the painter might call a complete landscape. The castle, with the serpentine part of the Wye below Chepstow, intermixed in a peculiar manner with the broad waters of the Severn, forms the fore-ground, which is backed by distant hills; the rocks, crowned with wood, lying between the alcove and the castle, to the right, and Castlehill farm, elevated upon the opposite banks of the river, to the left, form the two side-screens. This point is not marked, and must frequently be lost to the stranger. The grotto, situated at the head of Perse-wood, commands a near view of the opposite rocks, magnificent beyond description. The littleness of human art was never placed in a more humiliating point of view; the castle of Chepstow, a noble fortress, is, compared with the natural bulwarks, a mere house of cards.

Above the grotto, upon the isthmus of the Persefield side, is a shrubbery, strangely misplaced; an unpardonable intrusion upon the native grandeur of this scene. Mr Gilpin's observations upon this, as upon every other occasion, are exceedingly just. "It is a pity the ingenious embellisher of these scenes," says he, "could not have been satisfied with the great beauties of nature which he commanded. The shrubberies he has introduced in this part of his improvements, I fear, will rather be esteemed paltry." "It is not the shrub which offends; it is the formal introduction of it. Wild underwood may be an appendage of the grandest scene; it is a beautiful appendage. A bed of violets or of lilies may enamel the ground with propriety at the foot of an oak; but if you introduce them artificially in a border, you introduce a trifling formality, and disgrace the noble object you wish to adorn."

The walk now leaves the wood, and opens upon the lower lawn, until, coming near the house, it enters the alarming precipice facing Llancot; winding along the face of it in a manner which does great honour to the artist. Sometimes the fragments of rock which fall in its way are avoided, at other times partially removed, so as to conduct the path along a ledge carved out of the rock; and, in one instance, a huge fragment, of a somewhat conical shape, and many yards high, is perforated, the path leading through its base. This is a thought which will hand down to future times the greatness of the proprietor's taste; the design and the execution are equally great; not a mark of a tool to be seen; all appears perfectly natural. The arch-way is made winding, so that on the approach it appears to be the mouth of a cave; and, on a nearer view, the idea is strengthened by an allowable deception; a black dark hole on the side next the cliff, which, seen from the entrance before the perforation is discovered, appears to be the darksome inlet into the body of the cave.

From this point, that vast enclosure of rocks and precipices which marks the peculiar magnificence of Persefield is seen to advantage. The area, containing in this point of view the fields of Llancot and the lower margin of Perse-wood, is broken in a manner peculiarly picturesque by the graceful winding of the Wye; here washing a low grassy shore, and there sweeping at the feet of the rocks which rise in some places perpendicular from the water; but in general they have a wooded offset at the base,

Execution of the General Subjects.

above which they rise to one, two, or perhaps three or four hundred feet high; exposing one full face, silvered by age, and bearded with ivy, growing out of the wrinkle-like seams and fissures. If one might be allowed to compare the paltry performances of art with the magnificent works of nature, we should say that this enclosure resembles a prodigious fortress which has long lain in ruins. It is in reality one of nature's strongholds, and as such has probably been frequently made use of. Across the isthmus, on the Gloucestershire side, there are the remains of a deep intrenchment, called to this day the *Bulwark*; and tradition still teems with the extraordinary warlike feats which have been performed among this romantic scenery.

From the perforated rock, the walk leads down to the cold bath, seated about the mid-way of the precipice, in this part less steep; and from the cold bath a rough path winds down to the meadow, by the side of the Wye, from whence the precipice on the Persefield side is seen with every advantage; the giant fragments, hung with shrubs and ivy, rise in a ghastly manner from amongst the underwood, and show themselves in all their native savageness. From the cold bath upward, a coach-road, steep and difficult, leads to the top of the cliff, at the upper corner of the upper lawn. Near the top of the road is a point which commands one of the most pleasing views of Persefield; the Wye sweeping through a grassy vale which opens to the left; Llancot backed by its rocks, with the Severn immediately behind them, and which, seen in this point of view, seems to be divided from the Wye by only a sharp ridge of rock, with a precipice on either side; and behind the Severn the vale and wooded hills of Gloucestershire.

From this place a road leads to the top of Windcliff. The face of nature probably affords not a more magnificent scene. Llancot in all its grandeur, the ground of Persefield, the castle and town of Chepstow, the graceful windings of the Wye below, and its conflux with the Severn; to the left the forest of Dean; to the right the rich marshes and picturesque mountains of South Wales; a broad view of the Severn, opening its sea-like mouth; the conflux of the Avon, with merchant ships at anchor in King-road, and vessels of different descriptions under sail; Aust Cliff, and the whole vale of Berkeley, backed by the wooded swells of Gloucestershire, the view terminating in clouds of distant hills, rising one behind another, until the eye becomes unable to distinguish the earth's billowy surface from the clouds themselves.

The leading principle of the improvement proposed by Mr Wheatley is, to "separate the sublime from the beautiful; so that in viewing the one, the eye might not so much as suspect that the other was near.

"Let the hanging walk be conducted entirely along the precipices, or through the thickets, so as to disclose the natural scenery, without once discovering the lawn or any other acquired softness. Let the path be as rude as if trodden only by wild beasts and savages, and the resting places, if any, as rustic as possible. Erase entirely the present shrubbery, and lay out another as elegant as nature and art could render it before the house, swelling it out into the lawn towards the stables; between which and the kitchen-garden make a narrow winding entrance. Convert the upper lawn into a deer-paddock, suffering it to run as wild, rough, and forest-like, as total negligence would render it."

The visitor would then enter the hanging walk by a sequestered path at the lower corner of the lawn, pursuing it through the wood to beneath the grotto, and round the headland, or winding through Perse-wood, to the perforated rock and the cold bath, without once conceiving an idea that art, or at least that much art, had been made use of in disclosing the natural grandeur of the surrounding objects, which ought to appear as if they presented themselves to his view, or at most as if nothing was wanted but his own penetration and judgment to find them out. The walk should therefore be conducted in such a manner that the breaks might be quite natural, yet the points of view obvious, or requiring nothing but a block or stone to mark them. A stranger at least wants no seat here; he is too eager in the early part of his walk to think of lounging upon a bench. From the cold bath he would ascend the steep, near the top of which a commodious bench or benches might be placed. The fatigue of ascending the hill would require a resting-place; and there are few points which afford a more pleasing view than this; it is grand, without being too broad and glaring.

From these branches he would enter the forest part. Here the idea of nature in her primitive state would be strengthened; the roughnesses and deer to the right, and the rocks in all their native wildness to the left. Even Llancot might be shut out from the view by the natural shrubbery of the cliff. The lover's leap, however, might remain; but no benches, nor other work of art, should here be seen. A natural path, deviating near the brink of the precipice, would bring the spectator down to the lower corner of the park, where benches should be placed in a happy point, so as to give a full view of the rocks and native wildnesses, and at the same time to hide the farm houses, fields, and other acquired beauties of Llancot. Having satiated himself with this savage scene, he would be led, by a still rustic path, through the labyrinth, when the shrubbery, the lawn with all its appendages, the graceful Wye, and the broad silver Severn, would break upon the eye with every advantage of ornamental nature. The transition could not fail to be striking. And from this soft scene he would be shown to the top of Windcliff, where in one vast view he would unite the sublime and beautiful of Persefield.

One particular only remains to be noticed. A place which is the residence of a family all the year, is defective if some portion of it be not set apart for the enjoyment of a fine day, for air, and exercise, in winter. To such a spot shelter is absolutely essential; and evergreens being the thickest covert, are therefore the best; their verdure also is then agreeable to the eye; and they may be arranged so as to produce a beautiful mixture of greens, with more certainty than deciduous trees, and with almost equal variety. They may be collected into a wood; and through that wood gravel-walks may be led along openings of a considerable breadth, free from large trees which would intercept the rays of the sun, and winding in such a manner as to avoid any draft of wind, from whatever quarter it may blow. But when a retreat at all times is thus secured, other spots may be adapted only to occasional purposes, and be sheltered towards the north or the east on one hand, whilst they are open to the sun on the other. The few hours of cheerfulness and warmth which its beams afford are so valuable as to justify the sacrifice even of the principles of beauty to the enjoyment of them; and therefore no objections of sameness or formality can prevail against the pleasantness of a straight walk under a thick hedge or a south wall. The eye may, however, be distorted from the screen by a border before it, where the aconite and the snowdrop, the crocus and hepatica, brought forward by the warmth of the situation, will be welcome harbingers of spring; and on the opposite side of the walk little tufts of laurustines, and of variegated evergreens, may be planted. The spot, thus enlivened by a variety of colours, and even a degree of bloom, may be still further improved by a green-house. The entertainment which exotics afford peculiarly belongs to this part of the year; and if amongst them be interspersed some of our earliest flowers, they will there blow before their time, and anticipate the gaiety of the season which is advancing. The walk may also lead to the stoves, where the climate and the plants are always the same. And the kitchen-garden should not be far off; for that is never quite destitute of produce, and always an active scene. The appearance of business is alone engaging; and the occupations there are an earnest of the happier seasons to which they are preparative. By these expedients even the winter may be rendered cheerful in a place where shelter is provided against all but the bitterest inclemencies of the sky, and agreeable objects and interesting amusements are contrived for every hour of tolerable weather.

GARDINER, Stephen, bishop of Winchester and lord chancellor of England, was the illegitimate son of Dr Lionel Woodville or Wydeville, dean of Exeter, and brother to Elizabeth, queen-consort of Edward IV. He received his academical education at Cambridge, and, after passing some time in the family of the Duke of Norfolk, was appointed secretary to Cardinal Wolsey. This situation initiated him in the conduct of affairs, and proved the foundation of his rise at court. In 1525 he was employed to draw up the plan of the alliance with Francis I.; in 1527 he was sent to Rome to negotiate the divorce of Henry VIII. from Catharine of Aragon; and he advanced so rapidly in favour, that he was styled primary secretary of the most secret councils, and described by the cardinal-minister as *dimidium sui*, or the half of himself. During his residence at Rome, the pope having fallen dangerously ill, Gardiner set all engines to work to endeavour to obtain the keys provisionally for Wolsey, and secured the suffrages of about a third of the college of cardinals in behalf of his master; but this scheme was rendered abortive by the recovery of Clement. In the matter of the divorce, Gardiner reported that all solicitations at Rome would, in his opinion, be fruitless; that the pope was immoveable in the resolution to do nothing himself; but that he might be induced to confirm such a sentence as the king could obtain from the legates. Persuaded of the soundness, as well as sincerity of this opinion, Henry recalled Gardiner, and, soon after his arrival, declared him secretary of state. About this time, 1529, he obtained his first ecclesiastical preferment, the archdeaconry of Norfolk, which was conferred on him by Bishop Nix of Norwich. Gardiner was now particularly consulted by the king in the affair of the divorce; and when Cardinal Campejus declared the cause evoked to Rome, he found out Cranmer, and introduced him to the king, a step which proved the ruin of Wolsey. In 1531 he was installed in the archdeaconry of Leicester, and soon afterwards advanced to the rich see of Winchester. As Bishop of Winchester he assisted in the court, where, in May 1533, sentence was passed by Cranmer, declaring the king's marriage with Catharine null and void; and the same year he went as ambassador to the French king at Marseilles. On his return, being called on to acknowledge the king's supremacy, he readily complied, and published a defence of it, entitled *De Vera et Falsa Obedientia.* In 1535 he resumed his embassy to France, during which he declared against a religious league with the protestant princes of Germany, and advised a political alliance. In 1538 he was sent as ambassador to the German diet at Ratisbon, where he incurred the suspicion of maintaining a secret correspondence with the pope. On the death of Cromwell, long his rival in the king's favour, the university of Cambridge elected him its vice-chancellor; and, in return for this honour, Gardiner, on all occasions, gave it the benefit of his interest at court. But, like other courtiers, he was subject to all the vicissitudes of Henry's capricious favour; and, with all his suppleness and address, he on several occasions narrowly escaped imprisonment, if not something worse. This, indeed, is the more remarkable, as the proofs of his want of honest and sound principles are manifold. He was ever the servile and ready instrument of the king's will, and made no scruple in taking part in any proceeding, however disgraceful in itself, which seemed calculated to advance his interest or secure his safety. In the proceedings against Catharine of Spain, Anne of Cleves, Catharine Howard, Anne Boleyn, Sir Thomas More, and Bishop Fisher, Gardiner was equally active in lending himself to the vindictive caprices of the despot whom he served; and no motive of gratitude, no suggestion of humanity, no awakening of conscience, seem ever to have prevented him from yielding the basest compliance with the wishes of the tyrant. In the reign of Edward VI. he opposed the Reformation, and being deprived for disobedience and contempt, was imprisoned in the Tower; but on the accession of Queen Mary he was set at liberty, and again invested with power. The unprincipled sycophant under the wayward and ferocious Henry, now proved himself an unrelenting persecutor under the bigoted Mary; and it is even said that he was transported with joy on hearing of the martyrdom of Latimer and Ridley. But his career was now approaching to its close. He died on the 12th of November 1555, at the age of seventy-two. It is said that on his deathbed the retrospect of his life and conduct filled him with horror, and that he often repeated the words, *Erravi cum Petro, sed non flevi cum Petro*, I have sinned with Peter, but I have not wept with Peter. His principal works are, 1. De Vera et Falsa Obedientia, 1534; 2. Palinodia dicti libri; 3. A Necessary Doctrine of a Christian Man, set forth by the King's Majestie of England, 1543; 4. An Explanation and Assertion of the true Catholic Faith, touching the most blessed Sacrament of the Altar, 1551; 5. Confutatio Cavillationum quibus Sacrosanctum Eucharistiæ Sacramentum ab impiis Capernaitis impeti solet, 1551, composed while a prisoner in the Tower.

GARGARISM (from γαργαριζω, *to wash the mouth*), a gargle. Its use is to cleanse the mouth and throat with, when affected with inflammations, ulcerations, and the like.

GARLAND, a sort of chaplet made of flowers, feathers, and sometimes precious stones, and worn on the head in the manner of a crown. The word is formed from the French *guirlande*, and that of the barbarous Latin *garlanda*, or Italian *ghirlanda.* Ménage traces its origin from *gyrus* through *gyrulus*, to *gyrulare*, *gyrlandum*, *ghirlandum*, and at length *ghirlanda* and *guirlande;* but Hick rejects this derivation, and brings the word from *gardel handa*, which in the northern languages signify a *nosegay artfully wrought with the hand.*

GARNET, in *Natural History*, a beautiful gem, of a red colour, with an admixture of blue. See Gem and Mineralogy.

GARNET DENNIS, an island in the Eastern Seas, about forty-two miles in circumference, and inhabited by blacks. Long. 151. 25. E. Lat. 2. 30. N.

GARONNE, Upper, a department in the south-west of France, formed out of the ancient district Toulousain, a part of Upper Languedoc, and the district of Comminges, a portion of Gascony. It is bounded on the north by the department of Tarn-Garonne, on the east by those of the Tarn and the Aude, on the south-east by that of Arriège, on the south by Spain, and on the west by the departments of the Upper Pyrenees and the Gers. The extent is 2470 square miles, or, according to the royal almanack, 642,533 hectares. The civil divisions are four arrondissements, thirty-five cantons, and 605 communes, inhabited by 427,856 individuals.

The face of the country, in by far the greatest portion of the northern division of the department, consists of low hills, and broad valleys between them; but the southern part is a mountain district, which rises gradually towards the Spanish frontier, where some of the elevations attain the height of 10,000 feet. In the northern part the land is generally fertile; but in the southern it is sterile, and, in the valleys, is better adapted for pasture than for tillage. The chief river, which gives name to the department, is navigable for boats above Toulouse, to Cazères for small boats, and below that city to the sea for variously-sized larger vessels. In the Pyrenees are some small lakes: from one of them, the Seculego, is a waterfall into another, the Espingo, which is near 800 feet high, and the latter lake is 4500 feet above the level of the sea. In no part of the world is there a greater variety of picturesque scenery than the Pyrenees present within this department.

The inhabitants, like the others in these southern departments, speak a peculiar patois, in which many Latin and Spanish words are intermixed. In some parts of the Pyrenees, especially in the Valley of Luchon, are found the Cretins, there called Cagots, with large and indistinct articulation, and a great degree of stupidity, who reside in dwellings separated from the other inhabitants, by whom all connection with them is viewed with abhorrence. The singularity is, that none of this race are found on the Spanish side of the Pyrenees.

The agriculture, except on the mountains, is well conducted, and the harvests, especially of wheat, are very abundant; besides which, much maize is occasionally grown. The neighbourhood of Toulouse is one of the most fruitful of France, as well in corn as in pasture for cattle. Much fruit is produced, and the vineyards are extensive, yielding wine of a medium quality, most of which is consumed at home, or converted into brandy. The woods yield some ship-timber and fuel, but suffered much during the Revolution.

There are no mines worked except of iron upon a small scale, though copper and lead are to be found in several parts. The manufacturing industry is almost confined to Toulouse, the capital, where linen, woollen, and silk goods are fabricated extensively, as well as snuff, starch, china, paper, hats, hose, and some other articles. In the Pyrenees there is a considerable contraband trade carried on with Spain.

GARRICK, David, the greatest actor of his age and country, was born at the Angel Inn at Hereford, in the beginning of 1716. His father, Captain Peter Garrick, was a French refugee, and had a troop of horse, which were then quartered in that city. This rank he maintained in the army for several years, and had attained a majority at the time of his death, which, however, prevented him from ever enjoying it. Mr Garrick received the rudiments of his education in the free school at Litchfield, which he afterwards completed at Rochester, under the celebrated Mr Colson, afterwards mathematical professor at Cambridge. Dr Johnson and he were fellow-students at the same school; and it is a curious fact, that these two celebrated persons came up to London in the same coach, with the intention of pushing themselves into active life. On the 9th of March 1736, he was entered at the honourable society of Lincoln's Inn. The study of the law, however, he soon quitted, and followed for some time the employment of a wine-merchant; but that too having disgusted him, he at last gave way to the irresistible bias of his mind, and joined a travelling company of comedians at Ipswich in Suffolk, under the assumed name of Lyddal. Having in this poor school of Apollo gained some acquaintance with the histrionic art, he burst at once upon the world in the year 1741, in all the splendour of perfection, at the little theatre in Goodman's Fields, then under the direction of Henry Giffard.

The character which he first performed was that of Richard III., in which, like the sun bursting from behind a cloud, he displayed in the earliest dawn even more than noontide brightness. His excellence dazzled and astonished every one; and certainly, perceiving a young man, in his twenty-fourth year, and in reality a novice to the stage, reaching at one single step to that height of perfection which maturity of years and long practical experience had not been able to bestow on the most distinguished performers of the English stage, was a phenomenon which could not but become the object of universal speculation, and of as universal admiration. The theatres at the west end of the town were deserted; Goodman's Fields, from being the rendezvous of citizens and citizens' wives alone, became the resort of all ranks of men; and Garrick continued to act till the close of the season.

Having very advantageous terms offered him for performing in Dublin during part of the summer, he went over to that city, where he found the same just homage paid to his merit which he had received from his own countrymen. To the service of the latter, however, he esteemed himself more immediately bound; and therefore, in the ensuing winter, he engaged himself to Mr Fleetwood, then manager of Drury Lane. In this theatre he continued till the year 1745, when he again went over to Ireland, and continued there the whole season, as joint-manager with Mr Sheridan, in the direction and profits of the theatre-royal in Smock Alley. From Dublin he returned to England, and was engaged for the season of 1746 with Mr Rich at Covent Garden. This was his last performance as a hired actor; for in the close of that season Mr Fleetwood's patent for the management of Drury Lane being expired, and that gentleman having no inclination further to pursue a design by which, from his want of acquaintance with the proper conduct of it, or some other cause, he had considerably impaired his fortune, Mr Garrick, in conjunction with Mr Lacy, purchased the property of that theatre, together with the renovation of the patent, and in the winter of 1747 opened it with the greater part of Mr Fleetwood's company, and with the additional strength of Mr Barry, Mrs Pritchard, and Mrs Cibber, from Covent Garden.

Were we to trace Mr Garrick through the several occurrences of a life so active, busy, and full of events as his, we should swell this account beyond all due compass. Suffice it to say, that he continued in the unmolested enjoyment of his fame and unrivalled excellence to the moment of his retirement. His universality of excellence was never once attacked by competition. Tragedy, comedy, farce; the lover and the hero; the jealous husband who suspects his wife without cause, and the thoughtless lively rake who attacks her without design; were all alike his own. Rage and ridicule, doubt and despair, transport and tenderness, compassion and contempt; love, jealousy, fear, fury, and simplicity; all in turn took possession of his features, whilst each of them appeared to be the sole possessor of his heart. In the several characters of Lear and Hamlet, Richard, Dorilas, Romeo, and Lusignane; in his Ranger, Bayes, Abel Drugger, Kitely, Brute, and Benedict, you saw the muscular conformations which your ideas attached to them all. In short, Nature, the mistress from whom alone this great performer borrowed all his lessons, being in herself inexhaustible, this her favourite son, marked out as her truest representative, found an unlimited scope for change and diversity in his manner of copying from her various productions. There is one part of theatrical conduct which ought unquestionably to be recorded to Mr

Garrick's honour, since the cause of virtue and morality, and the formation of public manners, are considerably dependent upon it; and that is, the zeal with which he aimed at banishing from the stage all those plays which carry with them an immoral tendency, and pruning from those which do not absolutely, on the whole, promote the interests of vice, such scenes of licentiousness and libertinism as a redundancy of wit and too great liveliness of imagination have induced some of our comic writers to indulge in, and to which the sympathetic disposition of an age of gallantry and intrigue has given sanction. The purity of the English stage has certainly been much more fully established during the administration of this theatrical minister than it had ever been during preceding managements. He seems to have carried his modest, moral, chaste, and pious principles with him into the very management of the theatre itself, and rescued performers from that obloquy which had attached to the profession. Of those who were accounted blackguards, unworthy the association of the world, he made gentlemen, united them with society, and introduced them to all the domestic comforts of life. The theatre was no longer esteemed the receptacle of all vice; and the moral, the serious, the religious part of mankind, did not hesitate to partake of the rational entertainment of a play, and pass a cheerful evening, undisgusted with licentiousness, and uncorrupted by the immorality of the exhibition.

Notwithstanding the numberless and laborious avocations attendant on his profession as actor, and his station as manager, yet still his active genius was perpetually bursting forth in various little productions in the dramatic and poetical way, the merit of which cannot but make us regret his want of time for the pursuance of more extensive and important works. It is certain that his merit as an author is not of the first magnitude; but his great knowedge of men and manners, of stage effect, and his happy turn for lively and striking satire, made him generally successful; and his prologues and epilogues in particular, which are almost innumerable, possess such a degree of felicity, both in the conception and execution, as to be, in fact, unequalled. His ode on the death of Mr Pelham ran through four editions in less than six weeks. His ode on Shakspeare is a masterly piece of poetry, and, when delivered by himself, produced great effect. His alerations of Shakspeare and other authors have been at imes successful, and at times exploded. The exclusion of the gravedigger's scene from Hamlet will never be forgotten to him by the inhabitants of the gallery at Drury. Though necessary to the chasteness of the scene, they cannot bear to lose so much true sterling wit and humour; and it must be owned, that exuberances of this kind, though hey hurt the uniformity, yet increase the luxuriance of the ree. Amongst his alterations may be mentioned, Every Man in his Humour, altered from Ben Johnson; Romeo and Juliet, Winter's Tale, Catherine and Petruchio, Cymbeline, Hamlet, &c. altered and made up from Shakspeare; Gamesters, a comedy, from Shirley; Isabella, from Souherne. To these we may add, as original productions, The Farmer's Return, and Linco's Travels, interludes; Guardian, Lethe, Lying Valet, Miss in her Teens, Male Coquet, Irish Widow, and other comedies in two acts; Enhanter, a musical entertainment; and Lilliput. The Christmas Tale is ascribed to him, and many others.

We now bring him to the period of his retirement in the pring of 1776, when, full of fame, having acquired a splendid fortune, and advancing into years, he thought proper to seek the repose of private life, in order to enjoy that ignified and honourable ease which he had so well earned y the activity and the merits of his dramatic reign. But hort indeed was the period allotted to him for this tranuil enjoyment; for on the 20th of January 1779, he dearted this life, leaving no one rival in excellence upon earth to compensate for his loss, or a hope of our ever meeting with his like again. Garrick's Correspondence has recently been collected and published, in two volumes 4to, with a Life prefixed.

GARRISON, in the art of war, a body of forces, disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection, or even to be subsisted during the winter season. Hence *garrison* and *winter quarters* are sometimes used indifferently for the same thing, whilst at other times they denote different things. In the latter case, a garrison is a place in which forces are maintained to secure it, and where a regular guard is kept, as a frontier town, a citadel, castle, tower, and the like. The garrison should be always stronger than the townsmen. Du Cange derives the word from the corrupt Latin *garnisio*, which the later writers use to signify all manner of munition, arms, victuals, and the like, necessary for the defence of a place and sustaining a siege.

GARROWS, a mountainous district of Hindustan, on the north-east frontier of Bengal, tributary to the British. It is situated between the 25th and 26th degrees of north latitude. Its boundaries are said to be Rangamutty on the north and Assam on the east, though its limits have never been exactly ascertained. The country is mountainous, but fertile and tolerably well inhabited. The chief rivers which flow from the hills are the Nati, the Maharishi, the Sumaserry, and the Mahadeo. The rivers are of a sandy, gravelly bottom, and contain limestone and iron ore. In the bed of the Mahadeo is found abundance of coals: these might be a valuable article of import into Bengal; but the inhabitants, still in a barbarous state, are ignorant of the art of mining. The people are of a stout make, vigorous and athletic, but ill looking. They are not so dark as those in Bengal. They go nearly naked; and although calling themselves Hindoos, eat all kinds of food, and drink spirituous liquors. They worship Mahadeva; and at Banjam, a pass in the hills, they worship the sun and moon. They are poor and barbarous in their habits. Their houses are of the rudest description, being raised on piles three or four feet from the ground. The houses of the better classes are more neatly executed. They are said to be cheerful in their dispositions and mild in their manners. At the foot of the Garrow Hills reside a tribe of people called Hajins, who are more like the Hindoos, and who will not kill a cow.

GARSTANG, a market-town of the county of Lancaster, in the hundred of Amounderness, 228 miles from London. It was incorporated by Charles II., but returned no member to parliament. There is a market on Thursday. The population amounted in 1801 to 731, in 1811 to 790, in 1821 to 936, and in 1831 to 929.

GARTER, Order of the, a military order of knighthood, the most noble and ancient of any lay-order in the world, instituted by Edward III. The knights companions are generally princes and peers; and the king of England is the sovereign or chief of the order. The number of knights was originally twenty-six; but six were added in 1786, on account of the increase of the royal family. They are a college or corporation, having a great and little seal.

Their officers are a prelate, chancellor, registrar, king-at-arms, and usher of the black rod. They have also a dean, and twelve canons and petty canons, vergers, and twenty-six pensioners or poor knights. The prelate is the head. This office is vested in the Bishop of Winchester, and has ever been so. Next to the prelate is the chancellor, which office is vested in the Bishop of Salisbury, who keeps the seals. The next is the registrar, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order, with all fidelity. The Dean of Windsor is always registrar *ex officio*. The fourth officer is Garter and king-at-arms, being two distinct offices united in one person. The Garter carries the rod and sceptre at the feast of St George, the protector of this order, when the sovereign is present; he notifies the election of new knights, attends the solemnity of their installation, carries the garter to foreign princes, and others; and he is the principal officer within the college of arms, and chief of the heralds. (See KING-AT-ARMS.) All these officers except the prelate have fees and pensions. The college of the order is seated in the castle of Windsor, within the chapel of St George, and the charter-house, erected by the founder for that purpose. The habit and ensign of the order are, a garter, mantle, cape, george, and collar. The three first were assigned the knights companions by the founder, and the george and collar by Henry VIII.

The Garter challenges pre-eminence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes and absent knights, who, as well as all other knights-elect, are therewith first adorned; and it is of so great honour, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg, between the knee and calf, and is enamelled with this motto, *Honi soit qui mal y pense*; the meaning of which is, that King Edward having laid claim to the kingdom of France, retorted shame and defiance upon those who should dare to think amiss of the just enterprise he had undertaken for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order was such as would enable him to maintain the quarrel against those who thought ill of it.

The mantle is the chief of the vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle alone distinguishes the sovereign from the knights companions. To the collar of the mantle is fixed a pair of long strings, anciently woven with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robes, with knobs or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device. Within this is the cross of the order, which was ordained to be worn at all times by King Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver. The collar is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold. When the knights wear not their robes, they are to have a silver star on the left side; and they commonly bear the picture of St George, enamelled on gold, and set with diamonds, at the end of a blue ribbon, crossing the body from the left shoulder. They are not to appear abroad without the garter, on penalty of six shillings and eightpence paid to the registrar.

The manner of electing a knight companion into this most noble order, and the ceremonies of investiture, are as follows: When the sovereign designs to elect a companion of the Garter, the chancellor belonging to this order draws up the letters, which, passing both under the sovereign's sign manual and signet of the order, are sent to the person by Garter principal king-at-arms; and are in this manner, or to the same effect: "We, with the companions of our most noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shown, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c. have elected or chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation."

The garter, which is of blue velvet bordered with fine gold wire, having commonly the letters of the motto of the same, is, at the time of election, buckled upon the left leg by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion, by the Garter king-at-arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous; and having undertaken a just war, in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successfully conquer." The princely garter being then buckled on, and the word of its signification pronounced, the knight-elect is brought before the sovereign, who puts about his neck, kneeling, a dark blue ribbon, whereunto is appended, wrought in gold within the garter, the image of St George on horseback, with his sword drawn, encountering the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St George, by whose imitation provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory." Then the knight elected kisses the sovereign's hand; thanks his majesty for the great honour done him; and rises up and salutes all the companions severally, who return their congratulations.

Since the institution of this order there have been eight emperors and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related. The common account is, that the Countess of Salisbury at a ball happening to drop her garter, the king took it up and presented it to her with these words, *Honi soit qui mal y pense*, evil to him who evil thinks. This accident, it is said, gave rise to the order and the motto, it being the spirit of the times to mix love and war together; but as in the original statutes of this order there is not the least conjecture to countenance such a feminine institution, credit cannot be given to such tradition. Camden, Fern, and others, take it to have been instituted on occasion of the victory obtained by Edward over the French at the battle of Crescy. That prince, say some historians, ordered his garter to be displayed as a signal of battle; and in commemoration thereof, he made a garter the principal ornament of the order, erected in memory of this signal victory, and a symbol of the indissoluble union of the knights.

It appears from Rastel's *Chronicle*, that this order was devised by Richard I. at the siege of the city of Acre, when he caused twenty-six knights to wear thongs of blue leather about their legs, and that it was perfected in the nineteenth year of Edward III. In 1551 Edward VI. made some alterations in the ritual of this order, which he composed in Latin, the original being still extant in his own hand-writing. He there ordained that the order should no longer be called the order of St George, but that of the garter; and, instead of the george, hung at the collar, he substituted a cavalier bearing a book on the point of his sword, with the word *protectio* graven on the sword, and *verbum Dei* on the book.

GARTER principal King-at-Arms. This office was instituted by Henry V. Garter, and principal king-at-arms, are two distinct offices united in one person. Garter's employment is to attend the service of the order of the garter, for which he is allowed a mantle and badge, a house in Windsor Castle, and pensions both from the sovereign and knights, and, lastly, fees. He also carries the rod and sceptre at every feast of St George, when the sovereign is present, and notifies the election of such as are newly chosen; attends the solemnity of their installations, takes care of placing their arms over their seats, and carries the garter to foreign kings and princes; for which services it has been usual to join him in commission with some peer, or other person of distinction. The Garter's oath relates only to services being performed within the order, and is taken in chapter before the sovereign knights.

GARTER is also a term in heraldry, signifying the moiety or half of a bend.

GARTH, SIR SAMUEL, an English poet and physician, was descended from a good family in Yorkshire. He was admitted into the college of physicians at London in 1663. He at that time zealously promoted and encouraged the erecting of the dispensary for the relief of the sick poor, by giving them advice *gratis*, and medicines at low rates. This work of charity having exposed him and many other physicians to the envy and resentment of several persons of the same faculty, as well as apothecaries, he ridiculed them, with peculiar spirit and vivacity, in a poem called the *Dispensary*, in six cantos, which is highly esteemed. He was one of the most eminent members of the famous society called the *Kit Kat Club*, which consisted of noblemen and gentlemen distinguished by excellent parts, and affection to the house of Hanover. Upon the accession of George I. he was knighted, and made physician in ordinary to his majesty, and physician general to the army. Nor were these more than just rewards of his merit as a physician. He had gone through the office of censor of the college in 1702; and had practised with great reputation, and a strict regard to the honour and interest of the faculty, never stooping to prostitute the dignity of his profession, through mean and sordid views of self-interest, to any, even the most popular and wealthy characters. In a steady adherence to this noble principle, he concurred with the celebrated Dr Radcliffe, with whom he was also frequently joined in physical consultations. He had a most extensive practice, but was very moderate in his views of advancing his own fortune; his humanity and good nature inclining him more to make use of the great interest he had with persons in power, for the support and encouragement of other men of letters. He chose to live with the great in that degree of independence and freedom which became a man possessed of a superior genius, of which he was daily giving fresh proofs to the public. One of his last performances in polite letters was his translation of the fourteenth book, and the story of Cinnus in the fifteenth book, of Ovid's *Metamorphoses*. These, together with an English version of the rest, were published in 1717; and he has prefixed to the whole an excellent preface, in which he not only gives an idea of the work, and points out its principal beauties, but shows the uses of the poem, and how it may be read to most profit. The distemper which seized him the ensuing year, and terminated his life, caused a general concern, which was particularly testified by Lord Lansdowne, a brother poet. He died, after a short illness, which he bore with great patience, in January 1719.

GARVE, CHRISTIAN, an eminent German philosopher and essayist, was born on the 7th of January 1742, at Breslau, where his father exercised the trade of a dyer. He studied at the universities of Frankfort, Halle, and Leipsic, at which last place he obtained a professorship of philosophy; but was soon compelled to resign it, in consequence of bad health. He returned to his native town, where he continued to spend the remainder of his life in retirement. In his last years he suffered much from a painful and incurable disease, which he endured with the most philosophical fortitude. He died at Breslau on the 1st of December 1798. The character of Garve was exceedingly amiable, both as a man and a philosopher. His erudition was great; and his writings bear witness both to the extent of his knowledge and the accuracy of his judgment. Kant paid him the compliment of saying, that he was "a true philosopher, in the legitimate acceptation of the word." Garve invented no system of his own, nor did he attach himself to the tenets of any one master. He belonged to that class of philosophers who, without adopting any particular theory, take an impartial view of all systems of doctrine, and seek truth wherever it is to be found. The just and rational views which he inculcated on the subject of our moral and social duties, entitle him to the praise of a genuine practical philosopher. The history of philosophy is indebted to him for several new and ingenious illustrations; and he has left us a faithful though rapid sketch of the ancient and modern doctrines respecting the fundamental principles of moral philosophy. His style is uniformly simple, perspicuous, and correct.

The principal works of Garve are, 1. Dissertatio de nonnullis quæ pertinent ad logicam probabilium, 1766, 4to; 2. Dissertatio de ratione scribendi historiam philosophicam; 3. A Prize Essay in German, on the Inclinations, which was crowned by the Royal Academy of Berlin, 1769, 4to; 4. Progr. legendorum philosophorum nonnulla et exemplum, 1770, 4to; 5. Remarks on the character and writings of Gellert, 1770, 8vo, in German (this treatise was translated into French, and inserted in the French translation of Gellert's works by Pajon); 6. A dissertation, in German, on the union of morals and politics, Breslau, 1788, 8vo; also translated into French; 7. Essays, in German, on various subjects in literature, morals, and social life (of these, three volumes, we believe, were published during the author's life, and two have been added since his death); 8. A Sketch, in German, of the most remarkable principles of moral philosophy, from the time of Aristotle to the present day; which was first prefixed to his translation of Aristotle's Ethics, and afterwards printed separately, Breslau, 1798, 8vo; 9. Some observations on the most general principles of morals, in German, ibid. 1798, 8vo. Besides these works, Garve wrote a number of literary essays, which were inserted in various periodical publications. He also translated into German a variety of works, particularly from the English, many of which he enriched with valuable notes. Amongst these we may notice the Ethics, Rhetoric, and Politics of Aristotle; Cicero's Offices; Burke on the Sublime and Beautiful; Smith's Wealth of Nations; Fergusson's Principles of Moral Philosophy; and Paley's Principles of Morals and Politics. (See the *Biographie Universelle*, tome xvi. art. GARVE, by Degerando.)

GAS, in *Chemistry*, a general name for all permanently elastic fluids, which are obtained by chemical processes, as *azotic gas, muriatic acid gas, nitrous gas.* It is derived from the German *gascht* or *gast*, signifying the ebullition attending the expulsion of elastic fluids from substances in a state of effervescence.

GAS-LIGHT.

Importance of light.

Light, whether obtained from natural or artificial sources, is so necessary for the correct and successful execution of almost every operation of human industry, that whatever is calculated to simplify the means of procuring it, or to increase its intensity, cannot fail of being attended with the most beneficial consequences to civilized society. For every purpose to which it is applied, it must be admitted that the light of day, when it can be enjoyed freely and without interruption, is, by far, the most suitable; but in large and crowded cities, as well as in less favourable situations in point of climate, where the sun is sometimes shrouded for days together in dense and impenetrable clouds, it becomes expedient to compensate for the absence of his rays by artificial substitutes, which, however inferior in brilliancy and general usefulness, may nevertheless answer sufficiently well in those cases where a less ample supply of light is requisite.

Phosphorescent substances.

Some substances, denominated *phosphorescent*, have the property of absorbing the solar rays, on being exposed for a short time to their influence, and of emitting the light which they thus imbibe when they are afterwards placed in the dark; but the feeble and transient illumination which they shed, though sufficient to indicate their luminous condition, is totally unfit to afford such a supply of light as is necessary for conducting any of the operations of art, which must be performed with care and precision.

Substances from which artificial light is obtained.

During the process of combustion, however, a variety of inflammable substances, both of animal and vegetable origin, are found to give out light, as well as heat, when they undergo that species of decomposition; and hence, from the earliest periods of human society, it has been customary to burn substances of that description, for the purpose of obtaining artificial light. These substances, which were generally of a fatty or oleaginous nature, are found, when analyzed, to be composed chiefly of carbon and hydrogen. When they are exposed to a certain pitch of temperature they are resolved into some of the compound gases which result from the union of these elements, particularly carburetted and bicarburetted hydrogen, or olefiant gas, both of which are highly inflammable, and yield, during their combustion, a fine white light. To facilitate the decomposition, and carry on the combustion with due economy, a quantity of some fibrous substance, in the form of a wick, is connected with the oleaginous matter, for the purpose of causing it to burn slowly and effectually. Accordingly, if the flame be suddenly extinguished, the inflammable gas which is formed by the decomposition of the matter in immediate contact with the wick is observed to escape from it, and may be again set on fire by the application of a lighted taper.

When the light obtained from these substances must be frequently conveyed from place to place, no arrangement can be more convenient for their decomposition than that which is effected by means of the wick; but if it be to remain in a permanent position, it will frequently be more advantageous to resolve the oleaginous matter into gas, and then transmit it, in that state, through pipes, to the various points where it is to be consumed.

Though the different substances which have been used, from the earliest times, for yielding artificial light, have always been actually resolved into gas before they underwent the process of combustion, that fact was entirely unknown till pneumatic chemistry unfolded the properties of the aërial bodies, which perform so many important functions in the economy of nature, as well as in the processes of the arts. The use of gas for the purpose of illumination is therefore of recent date; but though late in its origin, the successive improvements which the invention has received, from the joint labours of chemists and practical engineers, have carried it, in a few years, to a pitch of perfection to which little can be added, either to simplify the processes for producing the gas itself, or improving its quality.

Discov of coal

Besides matters of an oleaginous nature, it has been ascertained that pit-coal and other bituminous substances yield, when they are exposed in close vessels to a high temperature, a large quantity of aërial matter, which is found to consist of various gases, most of which are extremely inflammable. This fact seems to have first attracted the notice of the Reverend Mr Clayton, who gives an account of it in a memoir on the subject, which he published in the Transactions of the Royal Society for the year 1739; and as his experiments furnish the earliest evidence of the possibility of extracting from coal, by means of heat, a permanently elastic fluid of an inflammable nature, we shall give the account of the discovery in his own words: "Having introduced a quantity of coal into a retort, and placed it over an open fire," he states that "at first there came over only phlegm, and afterwards a black oil, and then likewise a spirit arose which I could noways condense; but it forced my lute, or broke my glasses. Once when it had forced my lute, coming close thereto in order to repair it, I observed that the spirit which issued out caught fire at the flame of the candle, and continued burning with violence as it issued out in a stream, which I blew out and lighted alternately for several times. I then had a mind to try if I could save any of this spirit; in order to which I took a turbinated receiver, and putting a candle to the pipe of the receiver whilst the spirit rose, I observed that it catched flame, and continued burning at the end of the pipe, though you could not observe what fed the flame. I then blew it out and lighted it again several times; after which I fixed a bladder, squeezed, and void of air, to the pipe of the receiver. The oil and flame descended into the receiver, but the spirit still ascending, blew up the bladder. I then filled a good many bladders therewith, and might have filled an inconceivable number more; for the spirit continued to run for several hours, and filled the bladders almost as fast as a man could have blown them with his mouth; and yet the quantity of coals distilled was inconsiderable.

"I kept this spirit in the bladders a considerable time, and endeavoured several ways to condense it, but in vain; and when I had a mind to divert strangers or friends, I have frequently taken one of these bladders, and pricked a hole therein with a pin, and compressing gently the bladder near the flame of a candle till it once took fire, it would then continue flaming till all the spirit was compressed out of the bladder; which was the more surprising, because no one could discern any difference in the appearance between this bladder and those which are filled with common air."[1]

Experiments Mr M doch.

It is evident from this narrative, related with so much simplicity, that an accident which happened to Mr Clayton's apparatus was the means of leading to the discovery of coal-gas; but it does not appear that he or any other individual thought of applying the discovery to any practical purpose till the year 1792, when Mr Murdoch, who then resided at Redruth, in Cornwall, commenced a series of experiments upon the properties of the gases contained in different substances. In the course of his researches he found that the gas obtained by distillation from coal, peat, wood, and other inflammable substances, yielded a fine bright light during its combustion; and it occurred to him, that by confining it in proper vessels, and afterwards expelling it through pipes, it might be employed as a convenient and economical substitute for lamps and candles.

---

[1] Mr Clayton alludes to the discovery of the gas he obtained from coal, in a letter to the Royal Society, dated May 12, 1688.

Mr Murdoch's attention to the subject having been interrupted for some time by his professional avocations, he resumed the consideration of it in 1797, when he exhibited publicly the results of his more matured plans for the preparation of coal-gas. The following year he constructed an apparatus at Soho foundery for lighting that establishment, with suitable arrangements for the purification of the gas; and these experiments, Dr Henry states, "were continued with occasional interruptions until the epoch of the peace in 1802, when the illumination of the Soho manufactory afforded an opportunity of making a public display of the new lights; and they were made to constitute a principal feature in that exhibition."

In the brief sketch which we mean to give of the progress of gas-lighting, it may be noticed that the Lyceum Theatre in London was lighted with gas in the course of the years 1803–4, under the direction of Mr Winsor, who is entitled to no small commendation for the warm interest he took in drawing the public attention to the subject; and in 1804–5 Mr Murdoch had an opportunity of carrying his plans into effect on a still larger scale, by means of the apparatus erected under his superintendence in the extensive cotton-mills of Messrs Philips and Son of Manchester.

It has been alleged that gas-lights were used in France before that mode of illumination was known in this country; but as the earliest exhibition of these lights, on which the claim of priority of discovery is founded, took place at Paris in 1802, it is evident, from the foregoing statements, that the exhibition alluded to was ten years subsequent to the first experiments of Mr Murdoch on the subject.

It might have been interesting, in a statistical point of view, to have laid before our readers an account of the extent to which gas-lighting has been carried throughout the kingdom; but in a matter which is still in progress, it is not easy to procure documents that would be applicable to any particular period of time. At the close of the year 1822, it appears, by the report of Sir William Congreve, that the capital vested in the gas-works of the metropolis amounted then to about a million sterling; while the pipes, connected with the various establishments, embraced an extent of upwards of a hundred and fifty miles. So rapid, indeed, has been the progress of this new mode of illumination, that, in the course of a few years after it was first introduced, it was adopted by all the principal towns in the kingdom, for lighting streets, as well as shops and public edifices. In private houses it found its way more slowly, partly from an apprehension, not entirely groundless, of the danger attending the use of it; and partly, from the annoyance which was experienced in many cases, through the careless and imperfect manner, in which the service-pipes were at first fitted up. These inconveniencies have been, in a great measure, if not wholly removed, by a more enlarged knowledge of the management of gas; and at present there are few private houses, in large towns, which are not either partially, or entirely lighted up by it.

Of the Site and general Arrangement of the Apparatus for the Production and Purification of Coal-Gas.

Site and general arrangements.

In describing the site and general arrangements of a gas establishment, it is not easy to give directions respecting points, which must be regulated, in every case, by circumstances of a local nature; but when a choice of ground is in our power, a spot ought to be selected having a central situation with regard to the buildings, streets, &c. it is to supply with light, and standing as nearly as possible on a medium level with them. When the manufactory is placed considerably below that level, the gas is apt to be propelled with too much velocity through the burners; and when above it, an opposite inconvenience is experienced, the gas being in that case necessarily subjected to an extra pressure, by which the chance of its escape through any imperfection of the pipes is proportionally increased. Of the two evils, therefore, the least objectionable is that in which the situation of a gas-work is below the mean level of the streets.

But besides the conditions favourable to an equable and uniform distribution of the gas at the different points to which it may be conducted, there are other considerations scarcely less important, which, in selecting a proper site for the erection of the establishment, ought not to be disregarded. Among these may be reckoned a regular supply of water for the various manipulations of the work; and facility of access for the delivery of coal, and the removal of the coke, tar, and other products of the distillation. Nor, in fixing the situation of an establishment which is professedly erected for the public benefit, ought the comfort or the interest of individuals to be entirely overlooked; for though a gas-work may not prove, under proper management, a nuisance, it can never be considered to be any advantage to the neighbourhood in which it is placed.

Apparatus for the production and purification of gas.

The apparatus for the production and purification of coal-gas consist, in the first place, of suitable vessels for decomposing by heat the coal from which the gas is to be procured; secondly, of a series of pipes for conveying off the gas, and conducting it into proper receptacles, where it may be separated from the grosser products, which tend to impair the brilliancy of the light it is capable of yielding; thirdly, of the condensing apparatus, for removing more effectually the tar and other condensible substances that come over with the gas; fourthly, of the purifying apparatus, for abstracting the sulphuretted hydrogen, carbonic acid, &c. by which the gas is contaminated; and, fifthly, of the gasometer or gas holder, with its tank, into which the gas is finally received in a purified state.

Of the Retorts, or Vessels for decomposing the Coal.

The vessels employed for the decomposition of coal and other substances capable of yielding carburetted hydrogen, by their destructive distillation, are usually formed of cast iron, and termed *retorts.* Various shapes have been adopted in the construction of these vessels; nor have their forms been more varied than the modes in which they have been disposed, in the furnaces erected for their reception. In most instances, they have been constructed of a cylindrical shape, varying in length, and diameter. Those first employed were placed with their axis in a vertical direction; but experience soon showed that this position was extremely inconvenient, on account of the difficulty it occasioned of removing the coke, and other residuary matters, after the coal had been carbonized. Attempts were made to remedy this inconvenience, by enlarging the size of the retort, and introducing the coal enclosed in a proper grating of iron, having the form of a cage. The increased dimensions of the retort, from which the principal advantage to be derived from this arrange ment was expected, were found, however, to present great obstacles to the complete carbonization of the coal; for though the disengagement of gas during the first stages of the process was sufficiently copious, it diminished rapidly the longer the distillation was continued; a crust of coke being formed next the heated metal, which not only opposed the transmission of the temperature to the internal mass of coal, but gradually prevented, by its accumulation, the extrication of the gas from the undecomposed portion of it.

Modes of heating the retorts.

The retorts were, therefore, next placed in a horizontal position, as being not only more favourable to the most economical distribution of the heat, but better adapted to the introduction of the coal, and the subsequent removal of the coke, after the carbonization was carried to a due extent. At first the heat was applied directly to the lower part of the retort, but it was soon observed that the high temperature to which it was necessary to expose it, for the perfect decomposition of the coal, proved destructive to it, and rendered it useless long before the upper part had sustained much injury. The next improvement was accordingly to interpose an arch of brickwork between it and the furnace, and to compensate for the diminished intensity of the heat by a more diffused distribution of it over the surface of the retort. This was effected by causing the flue of the furnace to return towards the mouth of the retort, and again conducting it in an opposite direction, till the heated air finally escaped into the chimney.

Form of retorts.

This arrangement, which on the whole has been found to be the best, and is now generally used, seems to admit of little improvement, unless with respect to the shape of the retort. The cylindrical form has the advantage of possessing great durability, but it is not so well fitted for rapid decomposition of the coal (on which depends much of the good qualities of the gas) as the elliptical shape. Retorts presenting a saddle-shaped section, when they are supposed to be cut transversely, appear to be preferable even to those of an elliptical form; but the greater expense of casting them, together with their inferiority in point of durability, has prevented them from coming into extensive use.

Temperature best suited.

The temperature, best suited for the production of gas from coal, being what the workmen term a *bright red*, was found to be very destructive to the retorts, when they were exposed to the direct action of the fuel; and accordingly means were employed to protect them from the rapid oxidation which they suffered under these circumstances, by interposing between them and the furnace, a partition of fire tiles or arched bricks, with side flues for the admission of the heated air. This arrangement is represented in fig. 1, Plate CCLV., where *a* is the retort, *g* the grate of the furnace, *e* the fire-brick arch, and *f*, *f* the side flues.

Oven plan of setting retorts.

With the view of occupying less room, and saving the expense of fuel, several retorts are sometimes set together in an oven of brickwork, and heated by a smaller number of furnaces than there are of retorts. By this arrangement the fuel is certainly economized; but the plan is liable to the objection, that when any one of the retorts is worn out, those connected with it cannot be used till the faulty one is replaced; and though various expedients have been proposed for obviating that inconvenience, none of them can be said to have effectually answered the purpose. Fig. 2 and 3 represent varieties in the oven plan of setting retorts.

Fuel for carbonization.

The fuel required for carbonizing a given quantity of coal may be stated to be, in general, about two fifths of its weight. It has been affirmed, indeed, that the decomposition has been effected at some establishments with less than twenty-five per cent.; but if the retorts are maintained at a proper temperature, and the carbonization is carried to a due extent, the fuel, however well economized, will rarely be less than from thirty-five to forty per cent. of the coal it is employed to decompose.

Quanti of gas yielded coal.

The quantity of gas produced during the time the coal is undergoing decomposition is extremely variable. From a small retort, exposed for eighty-five minutes to a bright red heat, which was kept up with the utmost possible uniformity, the following results were obtained from eight pounds of the Wemyss coal:

	Cub. Ft.	Cub. In.
In 1st ten minutes	6	235
2d do	8	980
3d do	8	1254
4th do	5	784
5th do	4	1450
6th do	3	313
Last twenty-five minutes	6	1660
	43	1492

At the time the process was terminated the extraction of aëriform matter had nearly ceased, so that the quantity of gas yielded by a pound of the coal was about five and a half cubic feet. The same coal carbonized on the large scale yielded, when the process was carried on for four hours, at the rate of four and one third cubic feet of gas per pound. The weight of the coke in the above experiment was 32,050 grains; and as the weight of the gas, the specific gravity of which was ·65, must have been 15,026 grains, the tar and other residuary products, including the sulphuretted hydrogen abstracted by the process of purification, must have amounted to 8924 grains.

Quantit of gas obtained from difi rent kin of coal.

When the decomposition is effected on the large scale, the quantity of gas is found to vary with the quality of the coal, and the manner in which the operation is conducted. According to Mr Peckstone, a chaldron of Newcastle Wallsend coal yields 10,000 cubic feet, being at the rate of $370\frac{1}{3}$ cubic feet per hundredweight. At Edinburgh a hundredweight of cannel coal yields 430 feet and a similar return from coal of the same species is obtained at Glasgow, and other towns in Scotland.

Quality gas duri different stages of the carb nization.

The quality of the gas yielded by coal varies greatly at different periods of the carbonizing process. The first products, when the coal has not been previously well dried, consist almost entirely of aqueous vapour and carbonic acid; these are succeeded by light carburetted hydrogen, olefiant gas, and sulphuretted hydrogen, which gradually diminish in quantity till towards the close of the process, when almost the only products are carbonic oxide, and hydrogen. Hence if the process be carried on too long, the gases obtained in the latter stages of it will not only be useless for the purpose of yielding light, but the fuel employed for their production will be expended in wasting the retorts to produce substances which, we shall afterwards find, are calculated to impair the illuminating power of the gases with which they are mixed. In the case of cannel coal, the interval between the charges of the retorts should not exceed three and a half or four hours; nor in the case of the Newcastle coal, which is not so easily decomposed, ought that interval to extend beyond six hours.

The Condensing Main and Dip Pipes.

Use of t condensi main an dip pipe

From the retorts the gas, after its production, ascends by bent pipes, called the *dip-pipes*, into what is termed the *condensing main*, which is a large cast-iron pipe, about twelve or fifteen inches in diameter, placed in a horizontal position, and supported by columns in front of the brickwork which contains the retorts. This part of a gas apparatus is intended to serve a twofold purpose: First, to condense the tar and grosser products of distillation; and, secondly, to allow each of the retorts to be charged singly without permitting the gas produced from the rest, at the time that operation is going on, to make its escape. To accomplish these objects, one end of the condensing main is closed by a flanch; and the other, where it is connected with the pipes for conducting the gas towards the tar vessel and purifying apparatus, has, crossing it, in the inside, a semi-flanch or partition, occupying the lower half of the area of the section, by which the condensing vessel is always kept half full of liquid matter.

The dip-pipe, represented by *bcdh*, fig. 1, Plate CCLV., is connected by a flanch *i*, with a branch-pipe rising from the upper side of the condensing main; and as the lower end of it dips about two inches below the level of the liquid matter, it is evident that no gas can return and escape, when the mouth-piece *m* of the retort is removed, until it has forced the liquid matter over the bend *cd*; a result which is easily prevented by making *dh* of a suitable length. The upper part of the branch *bc* of the dip-pipe is generally furnished with a ground plug *p*, to allow the removal of the tarry matter, which is apt to accumulate, in a concrete state, at the lower part of the pipe where it is nearest the furnace.

Of the Tar Apparatus.

After emerging from the lower end of the dip-pipe, the gas, now bereft of a considerable portion of the vapour of water, tar, and oleaginous matter, which ascend with it from the retort, is conveyed by pipes, for the purpose of being completely freed from these impurities, into contrivances where a more perfect condensation takes place. As the subsequent purification of the gas depends, in no small degree, upon the perfect separation of the tar and other condensible products by which it is accompanied, the construction of the vessels best calculated for attaining that end, is a matter of the utmost importance; and indeed it may be justly affirmed, that unless that separation be effectually accomplished, the action of the chemical agents, to which the gas is afterwards exposed, must be limited and imperfect.

The first arrangements, employed for the purpose of condensation, were all constructed on the supposition that the object would be best attained by causing the gas to travel through a great extent of pipes, surrounded by cold water, and winding through it, like the worm of a still, or ascending upwards and downwards in a circuitous manner. One of these condensers is represented by figs. 4, 5, 6, and 7, Plate CCLV., where ABCD is the bottom of the condenser, and EGHF the top; IKLM and PQRO show the pipes in elevation. SKLT and SORT are sections of the vessel below the condenser, for the reception of the tar, and other condensible products. This vessel is divided by plates into a number of compartments which have no communication with each other, except at the bottom, for allowing the tar to be drawn off, by one discharging pipe *abc*. The gas is admitted at V, and after a repetition of ascents and descents, escapes at W, to be afterwards conveyed to the purifying apparatus.

A cylindrical pipe being the most capacious of all pipes having the same surface, an improvement upon the condenser as here described, was conceived to be gained by causing the gas to pass between plates of metal, forming a succession of narrow chests or galleries; an arrangement by which every portion of the gas being brought into more immediate contact with the sides of the condenser, it was concluded the condensation would be proportionally more complete. Such an apparatus is represented by figs. 8, 9, and 10, Plate CCLV., where ABDC represents the bottom of the condenser, E the entrance, and F the exit pipe of the gas, which passes between the plates, as indicated by the arrows. The bottom of the plates *a*, *a*, *a* have a slight inclination, so as to cause the condensed products to flow towards the openings *a*, *b*, *c*, where they are conveyed by pipes into the general receptacle below, and afterwards drawn off by the cock H.

Improved construction of the tar apparatus.

These tar vessels, and others of a similar form to accomplish the same purpose, are constructed on the supposition that the tar and other condensible products are held in a state of suspension in the gas by heat; and that nothing more is necessary to produce their deposition, than exposure to a reduced temperature. As it appeared, however, that a large portion of the gas, after leaving the condensing main, was enveloped in thin films of tar and oleaginous matter, it occurred to the writer of this article that the disengagement of it, from the vesicles in which it was enclosed, might be more effectually promoted by interrupting it in its progress through the condenser, than by mere exposure to cold; and in conformity with this idea, he found that when the gas was forced to make its way through brushwood, placed in proper vessels for the purpose, the separation of the tar was more complete, than by the ordinary modes of condensation. ABCD, fig. 1, Plate CCLVI., represents a tar condenser constructed on that principle. *a b c d* are large vessels, either of a square or cylindrical form, for containing the brushwood and loose materials through which the gas is made to pass; E being the pipe where it enters, and F the pipe where it escapes. *ef*, *ef*, pipes for conveying the condensed products into the horizontal pipe GH, which communicates with the tar receptacle M, by the bent pipe IK. The vessels containing the brushwood may be surrounded with cold water, or with the tar pumped up from the tar receptacle; but as the loose materials, through which the gas passes, seem to have the principal share in condensing the tar, it appears to be of little consequence whether the vessels containing it be surrounded with cold water or not, provided the apparatus be placed in a shaded situation. *m*, *m*, are man-hole doors for cleansing or removing the brushwood when it becomes clogged with tar; an operation which it may be necessary to perform once a year.

Of the purifying Apparatus for separating the Gases unfit for the purposes of Illumination.

Impurities of coal-gas.

With the two compounds of hydrogen and carbon, viz. olefiant gas, and light carburetted hydrogen, which are yielded by coal during its destructive distillation by heat, several other products are obtained, which are not only useless for the purpose of illumination, but calculated to diminish the brilliancy of the light which is afforded by these gases, and even to prove a source of serious nuisance during their combustion. Among these products of a deleterious nature, are carbonic acid, and sulphuretted hydrogen; and, in smaller quantity, carbonic oxide, nitrogen, and hydrogen. The first two are by far the most objectionable of these impurities; and fortunately, their separation can be effected more easily than that of the others, whose presence is of less importance.

How separated.

Carbonic acid is readily absorbed by any of the alkalis or earthy bodies, in a caustic state; and sulphuretted hydrogen, which possesses many of the properties of an acid, unites not only with the alkalis and alkaline earths, with which it forms a species of salts termed *hydrosulphurets*, but also with the metallic oxides, most of which it reduces.

Different states in which lime is used for the purpose.

The alkalis being too expensive to be used for separating carbonic acid and sulphuretted hydrogen from coal-gas, a more economical substitute, and which answers the purpose almost equally well, is found in quicklime. This substance is accordingly used in every gas establishment on the large scale, in some form or another, for the last step of the purifying process to which coal-gas is submitted to render it fit for combustion. It is employed in two states; either in the condition of a thin paste, which the workmen call the *cream* of lime, or of a moistened powder, such as lime assumes when it is slaked with a little more than the usual quantity of water. The apparatus must therefore be accommodated, in its construction and arrangement, to these different conditions of the purifying material.

Liquid lime, or cream of lime.

When the lime is used in a liquid state, the gas is made to pass through it so as to be as much as possible exposed to its action. One of the arrangements adopted for the purpose is represented by fig. 2, Plate CCLVI., where *aa* is an oblong close vessel, divided into a number of compartments formed by vertical partitions, which are fastened to the top and sides, but open at the bottom. The lower margin of the partitions is perforated with numerous small holes through which the gas passes from one compartment to another; the cream of lime being introduced in such quantity that its surface is above the level of the uppermost row of holes. The gas enters by the pipe *c*, and, after bubbling through the holes in the partitions, from cell to cell, makes its escape in a purified state by the pipe *d*. The liquid line is introduced from time to time at *b*, and run off, after being unfit for the purpose of purification, by the pipe *e*.

Purification promoted by agitation.

It being highly conducive to the success of the purifying process that a succession of fresh portions of the liquid lime should be brought in contact with the gas as it passes through it, the material is kept, at some establishments, in a state of constant agitation by means of machinery for the purpose. Fig. 3 represents an arrangement of that kind which is used at some of the London gas-works. *aaa* is a flat cylindrical vessel in which the purification is performed, the gas entering by the pipe *c* and escaping by the pipe *d*. In the inside of this vessel is another of a similar form *ff*, terminating at the bottom in a broad horizontal flanch or circular plate *gg*, and having revolving within it an agitator *hh*, which works in an air-tight stuffing box. The gas being forced by the pressure from the retorts to descend below *g*, is more effectually exposed in its progress to the action of the lime by the commotion produced by the agitator, and finally ascends, in a purified state, through the pipe *d*. Fresh portions of the purifying material are supplied from the vessel *k* by means of the connecting pipe *b*; and the cream of lime, after being saturated with the impurities, is withdrawn at *e*. In large establishments the gas is forced in succession through several vessels of the kind described, the cream of lime being changed in each of them at different times, to render its action more uniform and regular.

To supersede the necessity of using a series of purifiers, the following arrangement has been adopted, which seems well calculated to insure great regularity of action, with a simplification in the means of attaining it: *aa*, *bb*, fig. 4, is a cylindrical vessel, placed in a slanting position, and having a number of internal partitions *h*, *h*, rising nearly as high as its axis, in which there works a spindle *kk*, carrying round with it a number of arms of unequal lengths *l*, *l*. These arms act as agitators of the liquid lime contained in the different cells, formed by the partitions *h*, *h*. The cylinder *aa*, *bb* terminates at the upper extremity in a vessel *aa*, *ff*, which is surmounted by another vessel *agg*, in which the cream of lime is prepared. Through the opening *e* a vertical axis descends, giving motion to the inclined one *k* by means of two bevelled wheels. To the vertical spindle *ii* are attached an inverted cup *m*, operating as a valve; and the arms *n*, *n* for agitating the cream of lime before it is introduced into the vessel *aa*, *ff*. The gas is introduced at *c*, and escapes at *d*; and the cream of lime no longer fit for the purpose of purification is removed by the bent pipe *g*. The gas, ascending upwards in this machine, has to pass in its progress among all the arms of the inclined axis; and being thus exposed to the perpetual spray of the liquid lime, the supply of which is constantly and regularly renewed, it finally escapes at *d* in a purified state.

Objectio to the u of lime, the liqui state.

One of the objections against the method of purifying by the cream of lime, or lime in a liquid state, is, that unless the gas be previously freed entirely from tar, that substance, enveloping it with a thin film of oleaginous matter, which has little tendency to unite with water, carries the gas along with it in rolling bubbles, so that the internal parts of it can thus scarcely ever come into contact with the purifying materials. In some of the arrangements, indeed, which we have described, mechanical contrivances are employed to agitate and disperse the gas, with the view of exposing every portion of it, more or less, to the action of the lime; but these modes of promoting the efficacy of the process cannot be resorted to without the aid of some moving power, which, in many cases, must necessarily be attended with considerable trouble, as well as additional expense. There is another objection to which this method of purification, even if it required not the assistance of machinery, must always be liable; namely, that the olefiant gas upon which the illuminating power mainly depends, is largely absorbed by water, insomuch that either oil or coal gas, standing a few days over that fluid, suffers a great deterioration of its quality, and becomes in every respect less fit for the purposes of illumination. When lime is used in the dry state, or rather in the state of a moistened powder, for purifying coal-gas, neither of these objections is at all applicable; and when the arrangements for that mode of purification are contrived with a due regard to the simplicity and convenience of the manipulations, the separation of the useless and noxious gases is effected more easily, and not less effectually, than by the method of liquid lime. The abstraction of the sulphuretted hydrogen becomes more perfect, by adding to the lime a small portion of the peroxide of manganese, which being a cheap substance, adds very little to the expense of the process. This method of purifying coal-gas having been adopted with the utmost success in many gas establishments, we shall now proceed to explain the nature of the apparatus by which it is carried into effect.

Apparat for dry lime.

Figs. 1 and 2, Plate CCLVII., represent the elevation and plan of an apparatus for dry lime, with the valves for regulating the direction of the gas when the purifying materials require to be changed. PO and QR represent double chests, formed of plates of cast iron, and which are thus capable of being water-luted at *mn*, by means of an inverted vessel of the same form *abcd*, and which is made of sheet iron. This vessel, when the purifying process is going on, is kept down by means of cross bars *g*, *g*; and it is furnished with a stop-cock *k*, for allowing the common air to escape from it when it is let down into its position, and also for allowing the admission of that air, when it must be raised for the purpose of changing the purifying materials, without which the atmospheric pressure would render it extremely difficult to remove the vessel. *x*, *x* are bolt-eyes for hooking the tackle which is employed to lift the inverted chest *abcd*. The pipe T by which the gas is introduced rises above the level of the lime contained in the uppermost sieve, so that the gas, after issuing from it, spreads itself as pointed out by the arrows, and descends downwards through the several layers of lime *o*, *o*, till it reaches the bottom of the chest, where it makes its escape at V, to pass, if necessary, through a similar process in another chest. *h*, *h* represent sections of the valves, which are luted with mercury (or with water when they are made sufficiently deep), and arranged in such a manner that the pair G, H, and the pair L, M, one of which must always be open when the other is shut, are so connected by a chain passing over a pulley, that the same operation, which shuts the one, necessarily opens the other. The valves I and K, which must in some cases be both shut at the same time, are raised and depressed by separate levers. The weights N serve to keep the valves in their proper position, when they are adjusted to a particular mode of transmitting the gas.

Having thus given a general description of the various parts of the apparatus, we shall now proceed to explain the manner of managing the valves when the gas is to pass through either of the chests singly, or through both in succession. If it is to be transmitted through the chest OP only, then the valves H and M must both be open; and of course G and L would be shut; also both K and I must be shut. Again, if the gas were to be transmitted through the chest QR only, then the valves G and L must be open, and all the rest would be shut. Lastly, if the gas is to pass through both chests in succession, then the valves G, M, and K must be open, and all the rest shut; or if we wished to make the gas pass through the chests in a different order, the state of the valves might be reversed.

The quantity of lime necessary for purifying a given volume of coal-gas varies with the quantity of sulphur contained in the coal from which the gas is produced, and may be rated at from a tenth to a twentieth part of the weight of the coal. It is proper, however, to examine at intervals, during the progress of the purification, the state of the gas by such chemical tests as are calculated to detect the presence of any of the deleterious substances with which it is usually contaminated. Thus, carbonic acid is readily discovered by agitating a small portion of the coal-gas with lime water in a limpid state, the solution being quickly rendered turbid when the most minute quantity of that gas is present. Sulphuretted hydrogen is discovered with equal facility by causing a small current of coal-gas to play against a slip of paper moistened with a weak solution of acetate of lead, or nitrate of silver, both of which instantly become black when they are exposed to the action of sulphuretted hydrogen.

Having thus explained the nature of the various processes, by which coal-gas is freed from the different impurities with which it is contaminated, in the crude state, we shall next describe the structure of the vessels which are employed for storing it up, after it is duly purified and fitted for use.

Gasometers for receiving and containing the Gas before it is consumed.

As many disadvantages would be experienced by attempting to adjust the production of the gas to the rate of its consumption, it is found to be more convenient, as well as more economical, to store up such a portion of it, during the day, as shall compensate for the deficiency of the supply that may be furnished during the time the gas is consuming, in the course of the evening. The capacity of the vessels used for this purpose, which are called *gasometers*, must be regulated by a regard to that consideration.

The form of the gasometer is generally that of an inverted cylindrical cup, the diameter of which, when economy is studied, ought to be double of its depth, or at least not more than two or three inches less. Gasometers are usually composed of sheet iron, varying in weight from two to three lbs. to the square foot, well riveted at the joints, and kept in shape by means of stays and braces formed of cast or bar iron. The sheet iron is made to overlap at the joints, a slip of canvass well besmeared with white-lead being interposed to secure perfect tightness. The prismatic shape, though occasionally adopted, is not so convenient as the cylindrical, partly on account of the difficulty of making it retain its form, and partly on account of the greater quantity of material, compared with the capacity, that is necessary for its construction.

Tank of gasometer.

The gasometer is furnished with a tank, of the same form with itself, but a little larger in dimensions, for containing the water, in which it is suspended at different altitudes, by means of a chain and counterpoise, moving over pullies. The tank is sometimes built of stone, but more frequently it is constructed of cast-iron plates bolted together by flanches, with an interval between them of about three eighths of an inch, which is afterwards filled up with iron cement.[1]

Counter-poise and chain.

A gasometer, such as has been described, is represented by fig. 1, Plate CCLVIII., in which *aaaa* is the gasometer, *dd* the suspension chain, *cc* the pullies, and *e* the counterpoise; also *bb* is the tank, and *ff* the pipes for introducing, and conducting off the gas.

As the gasometer, when it is immersed in the water of the tank, suffers a loss of weight equal to that of the portion of fluid it displaces, it is evident that unless some arrangement be made to counteract the varying pressure which must thus result from the different depths to which it may be immersed, the gas contained in the gasometer will be expelled, at different times, with a varying force. If, however, the weight of the chain of suspension, or rather the weight of that portion of it whose length is the same as the height to which the gasometer ascends, be equal to half the loss of weight which the gasometer sustains by immersion in water, a perfect compensation will be made, and an equilibrium will hold between the gasometer and its counterpoise, at all altitudes. Thus, if the weight of the gasometer were five tons, or 11,200 lbs., and it lost by immersion a seventh part of its weight, or 1600 lbs., then the weight of that portion of the chain, equal in length to the highest ascent of the gasometer, would require to be 800 lbs., and the weight of the counterpoise 11,200 — 800, or 10,400 lbs.

	lbs.
For, the gasometer being immersed, its virtual weight is 11,200 — 1600, or	9,600
Weight of portion of chain now acting with the gasometer	800
Sum is the weight of counterpoise	10,400
Again,	
The gasometer being elevated out of the water, its weight is	11,200
Weight of chain now acting in opposition to it	800
Difference is the weight of counterpoise	10,400

Though the compensation, by this adjustment of the weight of the chain, answers the purpose in the most effectual manner, the following method is by some deemed preferable. Let the counterpoise (instead of having the form as shown at *e* in the figure) consist of a long cylindrical or prismatic body, as represented by the dots *g*, *g*, having the area of its horizontal section equal to the area of a similar section of the plates of the gasometer, and be allowed to descend into the water as the gasometer rises out of it. Also let the chain *d* be of a weight equal (length for length) to a column of water of equal bulk with the counterpoise. Then, if the weight of the gasometer be, as already supposed, 11,200 lbs., the weight of the counterpoise must be the same; but the weight of that portion of the chain which, by the above arrangement, was only equal to half the loss of weight sustained by the gasometer when immersed, must now be equal to the whole of that weight.

---

[1] The following iron cement is recommended by Peckstone: Take iron turnings or borings, and pound them in a mortar till they are small enough to pass through a fine sieve; then, with one pound of these borings, so prepared, mix two ounces of sal ammoniac in powder, and one ounce of flowers of sulphur, by rubbing them well together in a mortar; and afterwards keep the mixture dry till it may be wanted for use. When it is so, for every part thereof, by measure, take twenty parts of iron borings, prepared as above mentioned, and mix them well together in a mortar or other iron vessel. The compound is to be brought to a proper consistency by pouring water gently over it as it is mixing; and when used it must be applied between the flanches by means of a blunted caulking iron.

	lbs.
Then, the weight of the gasometer in the water is, as before	9,600
Weight of the chain now acting with the gasometer,	1,600
Weight of counterpoise, now out of the water	11,200
Again,	
The weight of the gasometer, out of the water, is	11,200
Weight of the chain, now acting in opposition to the gasometer	1,600
Weight of the counterpoise, in water	9,600

Pressure for expelling the gas.

Though we have only shown, in both these modes of compensation, that an equilibrium between the gasometer and its counterpoise holds, in the extreme cases, it would be easy to prove that the same thing must subsist, at all the intermediate elevations of the gasometer. At the same time it must be obvious that these contrivances, however well calculated they may be to secure the equilibrium alluded to, can have no effect in expelling the gas; and therefore, when it is wished that the contents of the gasometer shall issue from it under a certain pressure, the weight of the counterpoise must be diminished to a suitable extent. Thus, if it were required that the pressure employed for expelling the gas should be equal to that produced by a column of water three fourths of an inch deep, then it would be necessary to diminish the weight of the counterpoise by the weight of a column of water having the same diameter with the gasometer, and an altitude of three fourths of an inch. If the diameter of the gasometer above mentioned were, for example, 35 feet or 420 inches, the weight of a cylindrical portion of water having that diameter, and a depth of three fourths of an inch, would be, in grains,

$420^2 \times {\cdot}7854 \times \frac{3}{4} \times 252{\cdot}5 = 26236876$ grs. or 3748 lbs.

Hence it would be necessary to make the counterpoise 3748 lbs. lighter than it was supposed to be, according to the above-mentioned arrangements, in order that the gas might issue from the gasometer, under a pressure of three fourths of an inch of water. If the calculation were conducted with extreme accuracy, the specific gravity of the gas ought also to be taken under consideration; but the object to be attained is not of so delicate a nature as to require an attention to such minute circumstances. Besides, we shall afterwards find that the value of the arrangements we have described for obtaining an uniform and equable pressure is greatly diminished; and these are even entirely superseded by a contrivance called the governor, to be afterwards explained.

Particular forms of gasometers.

In situations where a sufficient depth of the tank cannot be easily obtained, an expedient may be resorted to, such as is represented in fig. 2. The gasometer consists of two parts, separable from each other; the one, *abba*, having the form of the common gasometer, and the other, *cccc*, being open at the top as well as the bottom, but connected with the other by a channel running around the bottom, which is filled with water. The lower part has a recurved form at the top; and this portion of it entering into the channel, becomes water-luted, by which the entire gasometer is rendered air-tight, at the line of junction. Various other contrivances have been proposed for saving room; but most of them answer the purpose so imperfectly, that they are scarcely deserving of being noticed. We shall, however, give a description of one of them, invented by M. Clegg, in which the gas is expelled by the partial revolution of the gasometer.

Revolv gasome

This kind of gasometer is represented in fig. 3, *aaa* being the cistern filled with water to the height of the dotted line; *b* the axle, which is hollow at each end, and works on friction sectors; *ddd*, a vessel supported by arms proceeding from the axle, and formed of parts of two concentric cylinders, shut at each end, and also at *g*, except where the entrance and exit gas-pipes passing from *g* to the hollow axis are connected (one of these only is shown in the figure, the other being directly behind it); the end *h* is left open, and when the gasometer is filled with gas it is just immersed in the water; *i* a pulley to which is attached a chain and weight *k*, disposed as represented. The whole apparatus is constructed so as to be an equilibrium in every position, the framing being made heavy at that part of the circle to which the gas-holder does not extend, so as to counterbalance the matter opposed to it. The gas enters at one of the hollow ends of the axis, and passes through one of the tubes *g* into the gasometer; and it is discharged under any required pressure, obtained by means of the weight *k*, through the other tube behind *g*, into the opposite extremity of the axis. Though this kind of gasometer is more expensive than one of equal capacity of the common form, yet requiring a shallow cistern for working in, it may be resorted to in some cases with advantage.

Pipes f introdu cing an dischar ing the

The gas is commonly introduced and conducted off by pipes, passing under the bottom of the tank for containing the water, in which the gasometer floats; and as these pipes are in many cases considerably below the level of the street pipes with which they communicate, they are apt to be filled up in the course of time with the condensed water which passes off in a vaporous state with the gas. To remedy this inconvenience, it is necessary to place vessels for receiving that water, in connection with the entrance and exit pipes, so contrived that the accumulated water may be easily removed from them when required. One of these vessels, which are improperly termed *syphons*, is represented by fig. 9. When the water rises to the height *d*, *e*, it is drawn off by means of a small suction pump, introduced into the pipe *ac*, which reaches within about an inch of the bottom of the syphon. To prevent too much water being removed, and thus allowing the gas to escape at *ac*, the lower end of the pipe of the suction pump should be perforated with small holes to as great a distance as the water is to be left in depth; or, if deemed preferable, the upper end of the pipe *ac* may be rendered air-tight by a screwed cap.

When access to the bottom of the tank is difficult, swivel or flexible-jointed tubes, disposed so as to rise and fall with the gasometer, are sometimes resorted to. Jointed tubes, connected by means of water-lutes, are also occasionally employed, and they are found to answer the purpose very well in situations where the water is not exposed to frost. One of these is represented in fig. 4, *a* being the pipe by which the gas is introduced, *b* a vertical pipe admitting of a small angular motion on the axis or support *c*, and connected with *a* by means of a water-lute joint. The upper end of *b* is united in a similar manner with one end of the pipe *d*, which is connected at the opposite end by means of a like entrance with the extremity of the pipe *f*, attached to the top of the gasometer; *g* is a regulating radius bar, centred to a bracket, which is fastened to the pipe *d*, and working on a fixed pivot at *i*. The gasometer, as it rises and falls, carries *f* along with it, and thus in the rest of the apparatus a motion is induced, corresponding with the connection of the different parts.

Of the Main and Service Pipes.

The gas being duly purified and prepared for combustion, the next point to be considered is the transmission of it from the gasometer to the various places where it is to be consumed. As it must sometimes be conveyed, particularly in the case of large establishments, to the distance of several miles, it is evident that unless the diameters of the various pipes through which it is to be conducted have a due relation to the quantity of gas to be transmitted, there will be a danger either of incurring an unnecessary expense, by making the pipes too large; or, what is still worse, of being exposed to a deficiency of supply, by making them too small. The first object, therefore, to be ascertained by the engineer, is the probable number of lights that may be required in the various streets and lanes in which these pipes are to be laid; and these being known, the corresponding quantity of gas, according to the quality of it, may be afterwards computed. With regard to the relative dimensions of the pipes at different distances from the gas-work, the only general rule to be observed is, that the sum of the areas of the sections of the main-pipes proceeding immediately from the gasometer, should be equal to the sum of the areas of the sections of the various branch-pipes which they supply with gas; and this rule, with some little modification, should be followed in the case of the subordinate ramifications.

In the case of good coal-gas, we may safely reckon that one fourth of a cubic foot of it will furnish the light of a moulded candle for an hour, of which one pound will, when the candles are burnt in succession, last forty hours. On this supposition, and assuming that the pressure upon the gas in the gasometer is equal to three fourths of an inch of water, the diameters of pipes necessary for conveying various quantities of gas may be stated as follows:—

Diameter of Pipe in Inches.	Quantity of Gas in Cubic Feet per Hour.	Equivalent Number of Candles.
$\frac{1}{4}$	4	16
$\frac{1}{2}$	20	80
$\frac{3}{4}$	50	200
1	90	360
2	380	1,520
3	880	3,520
4	1,580	6,320
5	2,480	9,920
6	3,580	14,320
7	4,880	19,520
8	6,380	25,520
9	8,090	32,360
10	10,000	40,000

This table has been deduced partly from theoretical considerations, and partly from the results of experiment. Peckstone affirms, in his work on Gas-lighting, that a pipe ten inches in diameter is capable of transmitting 50,000 cubic feet of gas per hour, under a pressure of one inch of water, while, according to the statement of Mr Creighton, such a pipe would scarcely convey the tenth part of that quantity, under a pressure of from four eighths to three fourths of an inch of water. It is impossible to reconcile these discordant statements, either by an allowance for the difference of pressure, or the difference of the specific gravities of the gases; for it ought to be kept in view that the discharge of gas is directly proportional to the square root of the height of the column of water by which it is pressed, and inversely as the square root of the specific gravity of the gas. Both of these propositions, however, must be greatly modified by friction, and consequently by the lengths of the pipes through which the gas is conveyed. In the supply stated to be furnished by pipes of different dimensions, we have deemed it safest rather to underrate the quantity, than overrate it.

The main-pipes are usually made of cast iron, joined together with socket joints, in lengths of three yards. The depths of the sockets vary in pipes of different sizes, from three to six inches, part of them being fitted with gasket to bring the centres of the pipes into line, and the remainder with lead after the gasket has been driven home with suitable chisels or caulking irons. The depth of lead to secure a good joint, should not be less than an inch and a half; the interval between the spigot and socket being from three eighths to seven eighths of an inch, according to the diameter of the pipe.

Necessity of giving pipes a proper inclination.

As a considerable quantity of water is carried off by the gas in the state of vapour, which is afterwards condensed in the pipes, some arrangement must be made for its collection and occasional removal; and accordingly, in laying the pipes, care must be taken to give them a regularity of declivity towards one or more points, where proper syphons, close vessels, and cocks must be placed, to receive and discharge the collected water. When these precautions are neglected, or when the levels are inaccurately taken, much annoyance is experienced; and as the evil can only be corrected by lifting and rejoining the pipes, the utmost attention should be paid to guard against it at first.

For stopping off the gas in large pipes, valves luted with water or mercury, according to the degree of pressure to be resisted, are usually employed. One of the most simple forms of these valves is represented in fig. 8, Plate CCLVIII. where *aa* is the valve, having the shape of an inverted cylindrical cup, which is raised and depressed by a rod *c* passing through an air-tight stuffing-box; and *bb* an annular cavity or interval, partially filled with water or mercury, into which the valve descends when it is shut.

Service-pipes.

To convey the gas from the main-pipes, and distribute it through the various apartments of dwelling-houses, pipes made of block-tin are generally used; these being more durable and better adapted to the purpose than pipes composed of copper or any other metal. In arranging the interior fittings, the same precautions must be observed as were recommended in the case of the main-pipes, viz. to give the various branches a due degree of inclination, so as to cause all the condensed water to flow to one or more points, where proper cocks must be placed for its removal. Unless this be done, the lights will be apt to flicker, or be extinguished at times altogether. Nor is it of trivial moment to enjoin the workmen, when they are soldering the service-pipes, to avoid with the utmost care allowing any of the melted metal to find its way into the inside of the pipes; it being in a great measure to this circumstance, that the deficiency in the supply of gas, so frequently complained of, is chiefly owing.

Of the Governor or Regulator.

Use of regulator.

The quantity of gas consumed in large towns varying greatly at different times, it is evidently a matter of some importance to the public, as well as to the manufacturers of gas, that the supply of it should be duly adjusted to the consumption; so that when the lamps are once regulated to a proper height of flame, they may continue afterwards to burn with the same steady light throughout the whole of the evening. Any contrivance that can accomplish so desirable an object must save a great deal of trouble to the consumer of gas, and much unnecessary waste of it to the manufacturer; and such is the design of the governor or regulator. Fig. 5, Plate CCLVI. represents one of these contrivances, *a* being the pipe proceeding from the gasometer, by which the gas is admitted, and *f* the pipe by which it escapes; *c* is a valve of a conical form, fitted to the seat *b*, and raised and depressed by means of the rod *dg*, to which it is attached; *ddd* is an inverted conical vessel, formed of sheet iron, which ascends and descends in the exterior vessel *ee*, in which water is contained to the level represented. The gas, entering at *a*, passes through the valve, fills the upper part of the inverted vessel *dd*, which it thus partially raises, and escapes at *f*. If the pressure from the gasometer be unduly increased or diminished, the buoyancy of *ddd* will be increased or diminished in like proportion, and the valve being by this means more or less closed, the quantity of gas escaping at *f* will be unaltered. And not only will the governor accommodate itself to the varying pressure of the gasometer, but also to the varying quantities of gas required to escape at *f* for the supply of the burners. Thus, if it were necessary that less gas should pass through *f*, in consequence of the extinction of a portion of the lights, the increased pressure which would thus be produced at the gasometer would raise the governor, and partially shut the valve, till the state of it was duly adapted to the requisite supply of gas.

Fig. 6 is another contrivance for the same purpose, which acts in a similar manner. The gas enters at *a*, and escapes at *f*. The valve *c*, with its stem, is attached to the inverted vessel *d*, which is suspended in a cistern of water *gg*, and moves upon a pivot at *c*. The action of this apparatus is the same as that of the contrivance we have already described. Both of them must be regulated by weights applied to the vessels *dd*; but these being once accommodated to the supply of gas, no further adjustment will afterwards be necessary.[1]

The Gas-Meter.

Design of the gas-meter.

The gas-meter is a simple but ingenious mechanical contrivance, the design of which is to measure and record the quantity of gas passing through a pipe in any given interval of time. The expense of these machines has hitherto formed the principal objection against their use; but already they are largely employed by several gas companies in England as well as in Scotland. They will probably be found, upon trial, to be no less advantageous to the consumer than to the manufacturer of gas, by allowing the former to use gas without any unnecessary waste of it, and securing to the latter a fair and regular price for the quantity of it actually consumed.

Fig. 7, Plate CCLVI., exhibits sections of one of these gas-meters, where *cc* represents the outside case, having the form of a flat cylinder; *a* is a tube which enters at the centre for admitting the gas, and *b* is another for conveying it off to the burners; *g*, *g* are two pivots, one supported by the tube *a*, and the other by an external water-tight cup, projecting from the outside casing, and in which is contained a toothed wheel *h*, fixed upon the pivot, and connected with a train of wheel-work (not shown in the figure) to register its revolutions. The pivots are fixed to and support a cylindrical drum-shaped vessel *ddd*, having openings *e*, *e*, *e*, *e*, internal partitions *ef*, *ef*, *ef*, *ef*, and a centre piece *ffff*, as represented in the figure. The machine is filled with water, poured in at *h* up to the level of *i*, and gas being admitted under a small pressure at *a*, it enters into the upper part of the centre piece, and forces its way through such of the openings *f* as are from time to time above the surface of the water. By its action upon the partition nearest in contact with the water (to the right hand of the figure, in which all the partitions or openings are shown), a rotatory motion is communicated to the cylinder; the gas from the opposite chamber being at the same time expelled by one of the openings *e*, and afterwards escaping at *b*, as already mentioned.

As the quantity of gas which passes through the machine in any given time depends not only upon its internal dimensions and the number of revolutions which it performs, but also upon the level of the surface of the water in which the cylinder revolves, due care must be taken to maintain the water at the same level, for the regular action of the meter. This is easily accomplished, by pouring in water when necessary, till the superfluous quantity is discharged by an orifice properly placed for the purpose.

Burners.

Principl upon wh the ligh yielded combustion, de pends.

The most economical mode of consuming gas, so as to obtain from a given volume of it the greatest possible quantity of light, both in degree and duration, is a problem of no less importance than that of the most suitable arrangements for its production and purification. The presence of oxygen, in some form or another, being essentially necessary to produce ordinary combustion, it follows, that from whatever cause that principle may be deficient in quantity, the combustion must be imperfect; and when this is the case, it appears that the light yielded by the combustible body is also diminished in a proportional degree. On the other hand, if the quantity of oxygen brought into contact with the combustible body be more than sufficient for its entire combustion, the superfluous quantity of that gas, instead of augmenting the effect, can only lower the temperature, and diminish, it may be presumed, in a corresponding degree, the intensity of the light. This must be the consequence if the brilliancy of the light yielded by a combustible body depends at all upon the temperature to which it is exposed during its combustion; and that this is the case may be inferred from the simple fact of causing the flame of a jet of gas to play, first against a sheet of ice, and then against a bar of red-hot iron, when the difference of the light will be such as to leave no doubt of the influence of temperature upon its intensity. A similar result is obtained by bringing the flames of two separate jets into contact, when an obvious increase of light is perceived. From these simple facts it may be inferred, that though a certain quantity of common air must be brought into contact with the inflamed gas to produce the greatest intensity of light, whatever exceeds that quantity will not only be useless, but, by diminishing the temperature of the flame, must tend to impair the brilliancy of its light.

But though the immediate cause of the light is probably the high temperature to which the carbonaceous portion of the gas is exposed, the condition in which the carbon exists, at the time it is so exposed, is of the utmost importance to the effect. According to the opinion of Sir Humphry Davy, as adopted by Drs Christison and Turner, "a white light is emitted only by those gases which contain an element of so fixed a nature as not to be volatilizable by the heat caused during the combustion of the gas; and that in coal-gas this fixed element is charcoal, formed by the gas undergoing decomposition before it is burnt. The white light is caused by the charcoal passing into a state, first of ignition, and then of combustion. Consequently no white light can be produced by coal or oil gas, without previous decomposition of the gas."

"That the gas undergoes decomposition before it burns, and that the carbonaceous matter is burnt in the white part of the flame in the form of charcoal, is shown by placing a piece of wire-gauze horizontally across the white part of the flame, when a large quantity of charcoal will be seen to escape from it unburnt. And that this previous change is necessary to the production of a brilliant white light, will appear, if we consider the kind of flame which is produced when decomposition does not previously take place. For example, if the gauze be brought down into the blue part, which always forms the base of the flame, no charcoal will be found to escape. Or, if the gauze be held at some distance above the burner, and the gas be kindled not below but above it, by which arrangement the air and the gas are well mixed previous to combustion, the flame is blue, and gives hardly any light. The reason is obviously, that in both cases the air is at once supplied in such quantity in proportion to the gas, that the first effect of the heat is to burn the gas, not to decompose it." (*Edin. Phil. Journ.* No. XXV.)

---

[1] The regulator, which was originally invented by Mr Clegg, was afterwards improved by Mr Crosley, who enjoys, by patent, the exclusive right of furnishing it. The gas-meter was also invented by Mr Clegg, and is constructed with great accuracy by Mr Crosley.

To these statements it may be added, that if a jet of oil or coal gas, burning with a fine yellow flame in common air, be suddenly surrounded with an atmosphere of oxygen gas, the colour instantly changes into a pale blue, yielding the most feeble light; nor does the flame recover its brilliancy till the oxygen is largely diluted with carbonic acid, when it burns for a short time with greater splendour than at first. For though the light is greatly enfeebled when the combustion of the gas takes place in pure oxygen, it becomes much more vivid when the combustion is carried on in air, which is more largely charged with oxygen than common air. Hence the brilliancy of the light appears to depend upon two conditions: 1*st*, The perfect combustion of a portion of the gas, in an undecomposed state; 2*dly*, the temperature produced by that combustion upon the residual part, in a decomposed state. When a large portion of the gas is consumed in the first condition, the temperature is higher; but the undecomposed part is then too small in quantity to yield an intense light, in consequence of the attenuated state of the carbon; and, on the other hand, when a small portion of the gas is consumed in the undecomposed state, the temperature produced is too feeble to raise the temperature of the now partially decomposed part to a sufficient pitch for the full ignition of the carbon.

The conditions which thus seem to be necessary for obtaining the greatest portion of light from the combustion of a given quantity of gas, while they are perfectly consistent with the most anomalous facts presented by that process, so they appear to afford the only sure principles upon which we can proceed in the construction of gas-burners. One of the most obvious conclusions deducible from these principles is, that whatever be the form of the gas-burner, its construction should be such, that while it admits as much air, it should never admit more than is barely sufficient for the perfect combustion of the gas.

According to the experiments of Drs Christison and Turner, the character best fitted for single-jet burners appears to be about one twenty-eighth of an inch for coal-gas, and one forty-fifth for oil-gas. As these dimensions, however, must vary with the quality of the gas, we consider one thirty-sixth of an inch to be more applicable to the gas obtained from cannel coal, if its specific gravity be not less than ·65. Every form of burner composed of separate jets, in which the gas is made to issue in a horizontal or oblique direction, gives a consumption which increases in a much faster ratio than the light which it yields; and consequently, however beautiful such burners may be in appearance, they are far from being economical.

One of the most useful forms of a burner with single jets, is where there are two holes, and their directions are so inclined as to cause the streams of issuing gas to cross, and exhibit during their combustion a broad continuous flame. This burner, which is termed a *swallow-tail*, is well adapted for street-lights, as it gives a powerful light, and consumes a small quantity of gas. When the gas is emitted by a narrow slit at the top of the burner, the burner receives the name of a *bat-wing*. Fig. 11, Plate CCLVIII.

But of all the forms of the burner, that upon the Argand principle, in which the holes are arranged in a circle, so as to admit the air to have access to the flame, externally as well as internally, is the most economical, and the best calculated to secure the complete combustion of the gas. The diameter of the holes should, in this burner, be about the fortieth part of an inch for coal-gas of an ordinary good quality, and the distance between them should be such as to allow the separate flame of the different jets to unite together and form a continuous hollow cylinder of light. Fig. 12.

The construction of burners, and the most economical mode of consuming gas, having been examined with much philosophical precision by Drs Christison and Turner, we shall extract from their elaborate dissertation on the subject, the most valuable and important conclusions which these learned individuals deduced from their experiments; and this we do with greater confidence, because the results they obtained coincide very exactly with those we procured, when engaged in the same inquiry. The three leading points to which they directed their attention were, 1*st*, the length of flame most suitable for different burners; 2*dly*, the form, magnitude, and position of the orifices through which the gas is discharged; and, 3*dly*, the modifications of the light produced by the glass chimney of the Argand burner.

Length of flame.

With regard to the length of flame which afforded the greatest light compared with the expenditure of gas, they found that, in the case of the jet, the best length for coal-gas was about five inches, and for oil-gas about four inches. When the flame was kept shorter, the quantity of gas consumed was greater in comparison of the light which it yielded; but no advantage was gained by increasing the length beyond that mentioned as the most suitable for each gas; the combustion becoming less perfect, and beginning to be accompanied with the escape of the carbon in the form of smoke. Thus they found that, in the case of coal-gas having the specific gravity ·602, while the lights emitted from a two-inch and a five-inch flame were as 556 to 1978, the corresponding expenditures were to each other as 605 to 1437. But the light, in an economical point of view, must be estimated inversely as the quantity of gas from which it is obtained; and hence the ratio of the lights, in reference to the expenditure, was as $\frac{556}{605}$ to $\frac{1978}{1457}$, being as 100 to 150.

In the case of Argand burners, the augmentation of the light, in a ratio greater than the expenditure, was exemplified in a still more remarkable degree. Thus the following results were obtained with coal-gas of the specific gravity ·605, by elevating the flame of a five-holed burner, successively from half an inch to five inches.

Length of Flame.	Half-Inch.	One-Inch.	Two-Inch.	Three-Inch.	Four-Inch.	Five-Inch.
Light..............................	18·4	92·5	259·9	308·9	332·4	425·7
Expenditure........................	83·7	148	203·3	241·4	265·7	318·1
Ratio of light to expenditure..	100	282	560	582	582	604

Hence the light is increased about six times for the same expenditure, by raising the flame from half an inch to three or four inches; but very little is gained by any additional increase of the flame beyond that length, in the description of burners with which the experiments were made.

These facts receive a satisfactory explanation from the general principles which we have already laid down with respect to the combustion of the luminiferous gases. When the flame is short, the supply of oxygen for the combustion is too great; almost the whole of the gas is thus consumed before any portion of it can undergo the decomposition which is necessary for the evolution of light; while the temperature of the flame being reduced by the superfluous air which brushes along its surface, the intensity of ignition, and with it the splendour of the light, is proportionally diminished. This explanation is well illustrated by partially shutting the central part of the burner, and thus interrupting the supply of air to the internal surface of the flame; the moment this is done, the length of the flame is increased, and a visible improvement of the light takes place, thus indicating that more air was previously brought in contact with the gas than was requisite for its perfect combustion.

Magnitude and position of the orifices. The second point to which Drs Christison and Turner directed their attention was the construction of the burner itself, particularly the magnitude and position of the orifices at which the gas is emitted during its combustion. The same principles which explained the relation between the light and the expenditure, in the case of flames of different lengths, suggested the rule for regulating the dimensions of the orifices; and accordingly they justly inferred that, in a single jet, the diameter of the aperture ought to be such as to ensure the complete combustion of the gas, without rendering it more vivid than is necessary for that effect. If the orifice be too small, the greater portion of the gas is liable to be consumed without suffering a previous decomposition, and thus the light is extremely feeble; and, on the other hand, if the orifice be too large, the surface of the flame exposed to the action of the air being too small in comparison of the discharge of gas, the combustion is imperfect, and the carbon, after being separated from the hydrogen, either burns at a low temperature with a dusky flame; or, what is still worse, a large portion of it passes off in the state of smoke. In conformity with these views, they recommend, as we have already stated, a twenty-eighth of an inch for coal-gas, and a forty-fifth for oil-gas, as the most suitable dimensions for single jets. They acknowledge, however, that their experiments with coal-gas were too limited to justify them in using very confident language on the subject; and we have therefore the less hesitation in stating that we consider an orifice, varying in diameter from a thirty-second to a thirty-sixth of an inch, as better adapted to coal-gas of a specific gravity between ·62 and ·70.

Orifices of Argand burners. In Argand burners the diameter of the orifices ought to be a little smaller. Drs Christison and Turner state that the diameter which appeared to answer best for coal-gas of the specific gravity ·6, when the holes are ten in a circle of three tenths of an inch radius, was a thirty-second of an inch. We consider this, however, to be too great for coal-gas of a better quality, and would recommend, in preference, apertures varying in diameter from a thirty-sixth to a fortieth of an inch.

Distance of jet-holes. The distance between the jet-holes of Argand burners is a matter of no less importance than the diameter of the orifices, and must be regulated by the same principles. When they are so far asunder that the flames of the separate jets do not coalesce, no advantage is derived from the Argand form; but when they unite, and compose an uniform and unbroken surface of flame, the light is considerably greater, compared with the expenditure of gas, than is obtained from detached jets. In order to determine the most suitable distance at which the orifices of Argand burners should be placed, Drs Christison and Turner took a burner six tenths of an inch in diameter, which they caused to be drilled with eight, ten, fifteen, twenty, and twenty-five holes, a fiftieth of an inch in diameter; and having determined, with each of these burners, the light and expenditure, in the case of oil-gas, they obtained the following results.

Burners.	VIII.	X.	XV.	XX.	XXV.
Light	360	360	391	409	382
Expenditure	367	318	296	289	275
Ratio of light to expenditure	98	113	132	141	139

As the standard of comparison was a single jet, burning with a four-inch flame, the ratio of the light yielded by which to the expenditure was expressed by 100, it was inferred that no advantage is gained by giving the jets the Argand arrangement with a burner of the dimensions above mentioned, if the holes are only eight in number; and that the gain does not increase after the number reaches to twenty. In the former case the distance of the holes must have been ·2356 inch, or nearly one fourth of an inch, and, in the latter, ·0945; so that the most advantageous distance for jet-holes of a fiftieth of an inch in diameter would seem to be about $\frac{9}{100}$ths of an inch. For coal-gas burners, however, the distance between the jet-holes ought to be increased in a ratio varying inversely with the quality of the gas, or directly as the diameters of the orifices themselves. Hence, if the coal-gas were of an ordinary quality, the jet-holes should not be less than one eighth nor more than one sixth of an inch from each other.

Diameter of circle of holes. The distance between the orifices being once assumed, serves to determine the diameter of the circle of holes. Thus, in a burner of eighteen holes, each a seventh of an inch asunder, the circumference ought to be $18 \times \frac{1}{7} = 2{\cdot}57$ inches, and consequently the diameter of the circle of holes should be $\frac{2{\cdot}57}{3{\cdot}1416} = {\cdot}818$ inch. If the breadth of the rim be supposed a tenth of an inch, and perhaps it ought not to exceed that quantity, it may be proper, in the case of the larger burners, to contract the lower part of the central air-hole, on account of the supply of air to the inside surface of the flame increasing in a faster ratio than the number of jets.

Glass chimney. The only remaining point to be considered with respect to the burner is the glass chimney, which serves at once to protect the flame from irregular currents of air, and to convey to the gas a due supply of it during combustion. When the interval between the chimney and the external part of the flame is too great, the tendency of the air to flow through the air-hole is diminished, and the flame contracts towards the top, where it yields a dusky light, and indicates a disposition to smoke. The diameter of the chimney should therefore be reduced until it is perceived that the upper part of the flame is enlarged, and acquires the same diameter as the lower part. When this is the case, the colour of the flame is improved in brightness, and none of the carbon is uselessly wasted in the formation of smoke. On the other hand, if the supply of air to the external surface of the flame be diminished beyond a certain extent, either by reducing the diameter of the glass chimney, or by any other means, the flux of air through the central air-hole is unduly increased, the flame diverges in the form of a tulip till it touches the chimney, and the supply of air to the outside of the flame being thus interrupted, smoke is again produced. Hence the greatest degree of light, in relation to the expenditure of gas, may be expected to be obtained when the supply of air to the external and internal surface of the flame is so adjusted by the diameter of the chimney that the flame is perfectly cylindrical, neither burning with too much vivacity, nor showing any tendency to smoke. The length of the glass chimney is of much less importance than its diameter, and may vary from five to six inches.

Apparatus for Preparing Oil-Gas.

When tallow or oleaginous matter of any kind is raised to a certain pitch of temperature, it is resolved into various gases, of which the compounds of carbon and hydrogen, viz. olefiant gas or bicarburetted hydrogen, and light carburetted hydrogen, are the principal, both in point of quantity and quality, for the purposes of illumination. As oil contains in its composition a portion of oxygen, existing most probably in union with hydrogen in the state of water, that substance also yields, during its destructive distillation, a considerable quantity of carbonic oxide, as well as traces of carbonic acid, hydrogen, and even nitrogen. With these products, all of which are of a determinate character, is found in greater or lesser abundance a quantity of a very inflammable vapour,[1] which seems to be a compound of carbon and hydrogen.

Oil-gas owes its illuminating power chiefly to the proportion of olefiant gas which it contains, and the oleaginous vapour which is diffused through it; and as both of these ingredients vary exceedingly with the temperature at which the decomposition is effected, the quality of oil-gas is extremely fluctuating. When the temperature is too high, a portion of the olefiant gas and oleaginous vapour is resolved, by the deposition of carbon, into light carburetted hydrogen; and though the quantity of gas from a given portion of oil is thus increased, the quality of it is diminished in a still higher ratio. On the other hand, if the temperature be rather too low, a larger quantity of olefiant gas, mixed with a greater proportion of oleaginous vapour, is obtained; but as the latter is gradually and rapidly condensed when the gas is allowed to stand over water, the higher illuminating power of this richer gas is more than counterbalanced by the deficiency in its quantity, and the deterioration to which it is liable by keeping.

We are indebted to Dr Henry of Manchester for the first analysis of the aëriform compounds obtained by the decomposition of oil by heat; and though his elaborate researches can scarcely be said to have led to the determination of the precise products of that decomposition, they furnish data from which their true nature may be inferred, with a probability nearly as great as that which belongs to the results of direct experiment. The principal difficulty of the analysis consists in determining the condition in which the elementary principles of carbon and hydrogen exist in union with each other, and reconciling the various suppositions that may be made respecting the compounds thus formed, with the specific gravity which belongs to the original gas, supposed to be produced by their mixture.

Gas-Light.

The results of Dr Henry's first experiments were published in 1805; but it was not till about ten years after that period that an apparatus for decomposing oil, on a large scale for economical purposes, was constructed. In 1815 a patent was obtained by Mr Taylor, in which he was afterwards joined by Mr Martineau, for producing gas from oil, by means of an apparatus which was employed with little variation in all the oil-gas establishments, which were subsequently formed in various parts of the country. The general arrangements adopted in that apparatus will be readily understood from figs. 5, 6, and 7, Plate CCLVIII.

The retort *aaaa*, has the form of a horse-shoe, being recurved and furnished with two mouth-pieces. The grate of the furnace is represented by *b*. The oil which is contained in the cistern *c*, is conveyed by means of a tube *tt*, furnished with a stop-cock for regulating the discharge, and allowed to drop into the retort upon fragments of brick or coke heated to redness, to promote the decomposition. The gas, after its production, ascends from the retort, at the opposite limb where the oil entered through the upright pipe *ff*, by which it is conveyed into a close vessel *hh*, which is surrounded with cold water in the cistern *ii*. From the bottom of the vessel *hh*, a worm or spiral tube *kk* ascends, and after a few convolutions around *hh*, terminates in the pipe *l*, which descends into the air-tight chest *mm*. The gas leaving the vessel *hh*, is conducted by the spiral tube *kk*, depositing in its progress any portion of the oil that may have come over with it in a volatilized state, and escapes from the lower end of the pipe *l*, into the chest *mm*, which contains water to the depth represented. After quitting the pipe *l*, the gas is forced to traverse the inclined partition *n*, in a zig-zag manner, by means of diagonal ribs attached to its lower side, till gradually ascending, it escapes at the upper end, and rising through the water, finally passes off at *g* to the gasometer.

Loss incurred by converting oil into gas.

Oil being decomposed at a loss of nearly fifty per cent. the conversion of it into gas, after a protracted, but ineffectual competition with coal, has been gradually abandoned on the large scale, even in those places where, from the interest they had in the whale-fisheries, there was the strongest inducement to foster the unfounded prejudices, which prevailed for some time against the use of coal-gas. The exaggerated advantages which it was pretended would be derived from compressing oil-gas, and thus rendering it portable, served to prolong the gross delusions on the subject, under which the public mind, led astray as it was, not less by novelty than by erroneous statements, so long laboured; nor were these delusions fully removed, until a demonstration was given of the failure of the scheme, in the decay of the costly edifices, and expensive apparatus, which, in defiance of all sober calculation, had been constructed for carrying it into effect.

Methods for determining the Illuminating Power of the Gases.

Having described at considerable length the nature of the various manipulations by which gas is prepared, both from coal and oil, we shall now explain the methods which seem best calculated to determine their respective illuminating powers; it being by these methods that we acquire a knowledge of one of the most important tests, by which the comparative value of the gases can be ascertained.

---

[1] The oleaginous vapour alluded to consists, according to the experiments of Mr Faraday, of two distinct compounds of carbon and hydrogen. One of these he terms *bicarburet of hydrogen*, which, by his analysis, is composed of six proportions of carbon and three of hydrogen. The other compound, to which Dr Thomson has given the name of *quadro-carburetted hydrogen*, consists of four proportions of carbon and four proportions of hydrogen, existing in a different state of aggregation from that in which they exist in bicarburetted hydrogen, the elementary constituents of which are in the same proportion.

Determination of the intensity of light, by the method of shadows.

The first and most obvious of these tests is to determine the intensity of the light which the gases are capable of diffusing during their combustion, upon a white and smooth surface, directly exposed to its emanations. The determination of that intensity is obtained with the greatest accuracy, not by a direct comparison of the degree of illumination shed on two separate surfaces, but by means of a happy contrivance, first proposed by Count Rumford, which allows the illuminated surfaces to be contrasted with each other on the same ground, and so closely adjoining, that the eye can readily detect the slightest difference between them. The contrivance, which is extremely simple and easily applied, is as follows: Let A and B, fig. 8, Plate CCLVI., be two luminous objects; EF a smooth and white surface, having the same inclination to the rays of light emitted by A and B; and CD an opaque cylindrical rod parallel to the surface EF; then it is evident that *aa* and *bb* will be the shadows of CD, in reference to the lights A and B. But the shadow *aa* being illuminated by the light B, and the shadow *bb* by the light A, it follows that if these shadows be perfectly the same, in point of intensity of shade, the light yielded by A and B must be the same in degree. If the shadows, however, be different, one of the lights must be removed either further from EF or brought nearer to it, until the shades seem to be exactly alike, when the light shed upon EF by A and B, must, in point of intensity, be, as before, the same. But the intensity of light, like that of other emanations proceeding in straight lines from a central point, being inversely as the square of the distance, the relative degrees of light emitted by A and B, must, in conformity with that principle, be proportional to the squares of their respective distances from the surface, on which the shadows are projected. Thus, if the light A was at the distance of fifteen feet, and the light B at the distance of twenty-five feet, their relative illuminating powers would be as the square of fifteen to the square of twenty-five; that is, as 225 to 625, or as 9 to 25. As the quantity of gas consumed in the same time to yield the supposed lights might be different, it is evident that a correct estimate of the absolute value of the gases, for the purpose of illumination, would not be duly determined, unless that circumstance were also taken into account. But the economical value of the gases, yielding equal degrees of light, being inversely as the quantities consumed, it follows that that value will be directly as the squares of the distances, at which the shadows are the same, and inversely, as the rate of consumption. Thus, if we now suppose that the gas yielding the light A consumed three cubic feet, in the same time that the gas yielding the light B consumed five cubic feet, the value of the former would be to that of the latter, as $\frac{9}{3}$ is to $\frac{25}{5}$, or as three to five. In obtaining the necessary data for determining the ratio of the lights, it may be proper to add, that the screen on which the shadows are projected should be guarded with the utmost care from all extraneous light. See PHOTOMETER.

Application of chlorine to determine the quality of gas.

Though the determination of the intensity of light by the method of shadows is extremely simple, and capable, when the necessary experiments are carefully managed, of leading to all the precision which the nature of the problem requires, it has been proposed, by those more conversant with chemical researches, to ascertain the relative value of the gases used for illumination, by finding the quantity of olefiant gas which they contain under equal volumes; it being assumed that the illuminating power of the compound combustible gases derived from the decomposition of oil and pit-coal, is directly proportional to the quantity of that gas existing in their constitution. Though that supposition is by no means a matter of certainty, or even of probability, we shall nevertheless briefly explain the mode of analysis which is recommended by those who have adopted it. According to the experiments of Dr Henry, chlorine has no action upon any of the gases obtained from oil or coal, when the influence of light is carefully excluded, with the exception of olefiant gas; and as chlorine and olefiant gas unite together in equal volumes, this property affords an easy mode of determining the quantity of the latter which may exist in any compound gas of which it forms a constituent part. All that is required for the purpose is to add somewhat more chlorine than is absolutely necessary for uniting with the olefiant gas, and to allow the mixture to remain about fifteen minutes completely excluded from light. The extent of the absorption being thus observed, half the quantity of the gas which has disappeared of the whole mixture will be olefiant gas. Thus, if twenty parts of chlorine by measure were added to twenty-five of coal-gas, and if the mixture, after being allowed to remain a sufficient length of time in the dark, was found to occupy thirty-six measures, the absorption would be nine measures, and consequently the coal-gas must have contained four and a half measures of olefiant gas, or eighteen per cent. The quantity per cent. of olefiant gas is determined without calculation, by adding to fifty measures of the gas to be analysed an equal volume of chlorine; when the diminution of volume, in the graduated jar, is the quantity which the gas contains per cent. of olefiant gas. Dr Fyfe states that the illuminating power of the different specimens of oil and coal gas which he subjected to this test bore a pretty exact ratio to the quantity of olefiant gas they contained. One great advantage to be derived from this method of testing the quality of any species of carburetted hydrogen containing olefiant gas in its composition, is, that it admits of a comparison being made between gases in different places and at different times, without the necessity of transporting them to a distance, and making a simultaneous examination of their illuminating properties.

Specific gravity o oil and co gas an imperfect te of their quality.

The specific gravity of oil and coal gas, and the quantity of oxygen which they require for their perfect combustion, have also been proposed as means of ascertaining their illuminating powers. The latter, however, even if it were a correct test, is determined with considerable difficulty; and that little reliance can be placed upon the former, may be inferred from the fact, that some of the gases which are component parts of oil and coal gas have a great specific gravity, without possessing any illuminating power. This will readily be perceived from the subjoined table.

Gases.	Specific Gravity.	Quantity of Oxygen for 100 Volumes.
Olefiant gas...........	·970	300
Carb. hydrogen.......	·556	200
Hydrogen..............	·069	50
Carbonic oxide........	·972	50
Carbonic acid.........	1·538	None.

Of these gases, carbonic oxide and carbonic acid possess the greatest specific gravity; while the latter is not only destitute of every illuminating property, but calculated, as we shall afterwards show, to deteriorate to a great extent the quality of the luminiferous gases with which it may happen to be mixed.

Comparative Merits of Oil and Coal Gas.

Though the examination of the relative values of oil and coal gas for the purposes of illumination might seem to be an inquiry little calculated to awaken party feeling, or lead to any great diversity of statement, there is perhaps no subject of investigation that has been conducted with less candour and impartiality. Nor is this remark merely applicable to the individuals who had an obvious interest in supporting the superiority of either gas; for even men of science, to whom it was apparently a matter of indifference which of the gases ought to be preferred, lent in too many instances their authority to the delusive and erroneous statements, which for a season misled public opinion on the subject.

As experience, the test to which all speculative doctrines relating to economy and public utility must ultimately yield, has already decided that, in this country at east, no establishment for manufacturing gas from oil can compete with one in which it is prepared from coal, it is ess necessary now than it was formerly to lay before our eaders a minute account of the comparative advantages of the two systems; but as there may still be cases where, rom the scarcity of coal and the abundance of oil, it might be doubtful which of them should be adopted, we hall briefly consider some of the leading points connected with the two modes of illumination. These may be discussed under the heads of, 1*st*, the illuminating power of he gases; 2*d*, their purity; 3*d*, their heating power; 4*th*, heir safety; and, 5*th*, their economy.

1st, *The Illuminating Power.*—This property may be considered either in regard to the relative light yielded by the flames of the gases, when equal surfaces are taken, r with respect to the absolute quantity of light furished by equal volumes of the gases. In the former ase, though the light of oil-gas is certainly more brilant than that of coal, the difference is so slight that it is difficult to detect it by the eye, or even by the method of shadows; but in the latter case, when the conumpt of the gas, as well as the light which it yields, is aken into account, it cannot be denied that the advanage is considerably in favour of oil-gas. In consequence, owever, of the great diversity of condition in which the wo gases are prepared, both with respect to their producon and purification, the most discordant statements have een given on this point. According to Mr Brande, oil-as and coal-gas give equal degrees of light, when their olumes are as one to two and a half; according to Dr yfe and Mr Leslie, when they are as one to one and a alf; and according to Mr Dalton, when they are as one two and a fourth. The greatest deviations were obined by Messrs Phillips and Faraday, and by Mr Ricardo, he former making the ratio as one to three and a half, nd the latter as one to four. The writer of this article, ho made the comparison between the two gases when ch of them was of the best quality, found that a very ense oil-gas, the specific gravity of which was 1·054, conmed at the rate of 2779 cubic inches per hour, and elded the light of thirteen and a half tallow candles, eing 206 cubic inches to give the light of a candle for hour; while a coal-gas, the specific gravity of which as ·675, consumed at the rate of 3900 cubic inches per ur, and yielded the light of thirteen candles, being 300 ubic inches to give the light of a candle for an hour. rom these experiments the illuminating power of the oil-s was to that of the coal-gas as 206 to 300. It may be oper to add, that the oil-gas, after being kept five days er water, consumed at the rate of 282 cubic inches per ur for the light of a candle, and that the coal-gas kept a similar manner, and for the same length of time, conmed at the rate of 409 cubic inches per hour, and gave the same degree of light. The deterioration produced on the oil-gas was therefore thirty-seven per cent. and that on the coal-gas about thirty-six and a third. According to the experiments of Drs Christison and Turner, when the oil-gas was of the best, and the coal-gas of average quality, their relative illuminating powers were as 100 to 260. This result, which was obtained from data obviously unfavourable to coal-gas, cannot be admitted as exhibiting a fair estimate of the illuminating power of the two gases; and as it may be presumed that, in some of the other experiments which they performed with a view to determine the same point, the effect of keeping the gases for different lengths of time over water may have been overlooked, the results they obtained, which make the relative powers of illumination as 100 to 233, are of less value. It appears that oil-gas suffers more by keeping, even when it is not preserved over water, than coal-gas. This seems to be owing to the deposition of an ethereal oil, already noticed, which remains suspended in the gas for a short time after it has been prepared, but which gradually separates from it when it cools, or is allowed to remain in a state of repose. It is a singular fact, that though the specific gravity of oil-gas, after it has been conveyed for some distance through pipes, is materially diminished by the loss of this oleaginous vapour, scarcely any trace of the latter is to be found in the vessels for collecting the condensed matter, between the manufactory and the houses of the consumers of the gas. The deterioration, however, is undoubted, and in some cases it amounts to thirty per cent. We have even found that the best oil-gas, if kept for several weeks over water, becomes so much debased in quality as to require 600 cubic inches per hour to yield the light of one candle. Coal-gas suffers also by keeping, but in an inferior degree; the olefiant gas, which it contains less abundantly, being more largely absorbed, in the case of oil-gas, by the water over which it stands.

Deterioration of gas by keeping it over water.

Relative illuminating power of oil and coal gas.

The mean result deduced by the writer of his article, from a very considerable number of experiments performed with great care, and by means of suitable apparatus for the purpose, is that 100 cubic inches of oil-gas are equal in illuminating power to 160 of coal-gas, both being of good quality. The coal-gas, it may be proper to mention, was produced from cannel coal, and purified without coming in contact with water, by dry lime, or at least quicklime slightly moistened, and mixed with a small portion of the peroxide of manganese. The oil-gas was in most cases obtained by the patent apparatus of Taylor and Martineau.

Purity of oil and coal gas.

2d, *The Purity.*—Under the head of purity we may consider the offensive smell belonging to the materials from which the gases are obtained; to the products connected with their decomposition; and also to the gases themselves, as well as the tendency which the gases may have to produce, during their combustion, substances capable of being deleterious to health, or injuring any kind of household furniture exposed to their influence. With respect to the first of these nuisances, it cannot be doubted that oil is more apt to prove offensive to the neighbourhood than coal. The latter, if kept for some months, only loses the water it had imbibed in the bowels of the earth, and is thus rendered more fit for yielding a better gas, as well as one more abundant in quantity; whereas the former becomes rancid and fetid by keeping, and emits, by exposure, effluvia which are equally offensive and unwholesome. The mere emptying of oil from one vessel to another, and especially the melting of some kinds of it, which is necessary before it can be introduced into the retorts, is attended with a degree of nuisance which no caution can entirely prevent. To counterbalance these disadvantages, it must be admitted that the products which result from the decomposition of coal are not only of a more offensive nature, but more abundant in quantity than those which are obtained from oil; and though the extent of the nuisance which they occasion is greatly diminished in well-regulated coal-gas works, by confining them in close vessels, it is impossible altogether to prevent the annoyance to the neighbourhood, which their removal from time to time produces.

Smell of the gases.

With respect to the smell of the two gases, they are so nearly the same when the gases are properly purified, that it would be difficult to pronounce which of them is least unpleasant. At any rate, when they are properly burnt, and consumed without any portion of them being permitted to escape, no disagreeable odour is perceptible; and, in this respect, either of them has a decided advantage over tallow or oil used for the purpose of yielding light, and burnt, according to the ordinary mode, with a wick.

Impurities of coal-gas, in its crude state.

The most serious objection, however, against the use of coal-gas, was grounded on the various impurities with which, in its crude state, it is more or less contaminated. These impurities consist, as already stated in a preceding part of this article, of tar, carbonic acid, sulphuretted hydrogen, and carbonate of ammonia, some of which are so offensive that, without being freed from them, coal-gas could never be brought into competition with oil-gas. When coal-gas was first introduced, neither the tar nor the sulphuretted hydrogen was so completely separated from it as to render it fit for being used in private dwelling-houses; and accordingly strong prejudices continued to operate against it, long after the cause which gave them birth had ceased to exist. As it is now generally admitted, however, that coal-gas is so effectually purified, in many establishments for its production, as not to exhibit the slightest trace of sulphur when exposed to the most delicate tests for detecting the presence of that substance, its value for the purpose of illumination, as contrasted with that of oil-gas, must rest chiefly on considerations of economy. It has been alleged, indeed, by Mr Brande, that though no indications of the existence of sulphur in coal-gas could be discovered in it before it was burnt, he could never procure any which did not afford traces "very minute" of sulphurous acid during its combustion. But if he had submitted oil-gas to the same ordeal he would have obtained a like result; a portion of sulphur being expelled from the coke which is used in the retorts for decomposing the oil, and which sulphur accordingly unites itself with the gas at the moment of its formation, and may be detected by exposing the condensed aqueous vapour which is formed during its combustion, to the action of the nitrate or acetate of barytes. In this respect, therefore, the two gases must be admitted to be on the same footing.

Aqueous vapour generated during the combustion of the gases.

Under the head of purity it may not be improper to notice the quantity of aqueous vapour which is produced during the combustion of the gases, by their union with the oxygen of the atmosphere, as the water thus formed may be conceived to possess in some measure the character of a nuisance. To obtain a correct estimate of the quantity of this water, generated in any case, it will be necessary to take into account the proportional relation between the volumes of the gases yielding equal degrees of illumination, and the quantities of hydrogen contained in these volumes. With respect to the former of these points, we have already stated that 100 volumes of oil-gas are equal to 160 of coal-gas; but the actual composition of the gases is still involved in some obscurity. According to the experiments of Dr Henry,[1] 100 measures of oil-gas having the specific gravity ·906 contained 38 of olefiant gas, of which, by the acknowledged constitution of that gas, 76 must have consisted of hydrogen in a condensed state. The remaining 62 parts were composed, by the analysis of that able chemist, of

Nitrogen	3.1
Carb. hydrogen	46·5
Carb. oxide	9·3
Hydrogen	3·1
	62

But 46·5 parts of carburetted hydrogen contained, in a condensed state, 93 parts of hydrogen; to which adding the simple hydrogen 3·1, and the portion of the same gas contained in the olefiant gas 76, we obtain 172·1 for the whole quantity of hydrogen in the oil-gas.

Again, Dr Henry states that 100 measures of coal-gas having the specific gravity ·650 yielded thirteen of olefiant gas, which therefore contained in the condensed state 26 of hydrogen. The remaining 87 parts consisted, according to his analysis, of

Nitrogen	1·3
Carb. hydrogen	82·2
Carb. oxide	3·5
	87

But as 82·2 parts of carburetted hydrogen must have contained, in the condensed state, 164·4 parts of hydrogen; if to this be added the hydrogen of the olefiant gas 26, we obtain 190·4 for the whole quantity of hydrogen in the coal-gas. Combining the results thus obtained with the numbers expressing the ratio of the volumes of the gases, giving equal degrees of illumination, it appears that the quantity of water generated by oil-gas will be to that generated in the same time by coal-gas, as 100 × 172·1 to 160 × 190·4, being as 17,210 to 30,464, or as five to nine nearly. Hence coal-gas must produce nearly twice as much watery vapour in an apartment, during its combustion, as oil-gas yielding the same degree of illumination.

Calculation of t quantity aqueous vapour.

To determine how far the moisture thus generated may be regarded as a nuisance, we shall make an exact calculation in the case of an apartment, which we shall suppose to be twenty feet long, sixteen feet broad, and eleven feet high, and containing therefore 6,082,560 cubic inches. To light a room of these dimensions in the way commonly done with coal-gas would require three Argand burners, each yielding the light of ten candles, and consuming about 10,000 cubic inches of gas per hour. Now, as 100 cubic inches of coal-gas of ordinary quality contain, as we have already seen, 190·4 of hydrogen in a condensed state, the quantity of the latter gas consumed by the burners would be 19,040 cubic inches, which would yield 4284 grains of aqueous vapour per hour. This quantity of water, diffused equally over the whole apartment, would add about $\frac{1}{1500}$th part of a grain to the moisture previously existing in each cubic inch. This may appear to be a very inconsiderable quantity; but as it is about a fifth part of the whole of the moisture capable of existing in the air of the atmosphere at the ordinary temperature of our rooms in winter, it would be sufficient to occasion perfect dampness in an apartment, at that season, in the course of four hours. In consequence, however, of the external cold, this state of things never takes place, the greater part of the floating vapour being reduced to the liquid form by condensation against the windows, long before the air of the apartment is generally affected by it.

Heatin power the gas

3d, *The Heating Power.*—As the heating power of gas may be regarded as being, in many cases, an advantage rather than a nuisance, we shall merely state the results produced by the combustion of certain volumes of oil and coal gas, in reference to the light which each of them yielded, when they were exposed to that process. The apparatus we used for the purpose was extremely simple, and of the following construction: *abefghcd*, fig. 9, Plate CCLVI., represents a double vessel, composed of two concentric cylinders of tin-plate, which was furnished with a lid; the external cylinder, *abcd*, was six inches in diameter, and the internal one, *fehg*, three inches, the former being twelve inches deep, and the latter six. From the bottom of the internal cylinder proceeded two tin tubes, *ikl*, the use of which was to carry off the air contaminated by combustion. When he apparatus was used, a quantity of water at a fixed temperature was poured into the space between the cylinders, ill it stood at a mark *nn* in the inside; a burner *m*, consuming a known quantity of gas, and yielding a light equal o that of a certain number of candles, was then introduced, nd allowed to remain exactly at the same distance from *fg*, ill the water reached a given temperature, the time of its loing so being carefully noted with a seconds watch. To guard against the errors arising from the dissipation of the heat during the progress of the experiments, equal porions of pounded ice were sometimes mixed with the water, nd a thermometer was applied from time to time to the pper extremities of the tubes *ikl*, to ascertain whether ny of the heated air escaped before it imparted the whole f its calorific influence to the water.

---

[1] *Transactions of the Royal Society for* 1821.

The following result was obtained with oil-gas having he specific gravity ·970, the rate of consumpt being 3054 ubic inches per hour, with the light of 10·55 candles.

Temperature of water at commencement	49°·0
After ten minutes	85 ·5
... twenty ditto	115 ·0
... thirty ditto	139 ·5
... forty ditto	161 ·0
... fifty ditto	181 ·0
... sixty ditto	195 ·5

Hence 3054 cubic inches of oil-gas raised the temperaure of 270 cubic inches of water 146°½ in an hour.

Again, with coal-gas the specific gravity of which was 50, and which consumed at the rate of 3583 cubic inches er hour when it yielded the light of ten candles, the llowing results were obtained:—

Temperature of water at commencement	48°·0
After ten minutes	81 ·0
... twenty ditto	113 ·8
... thirty ditto	140 ·5
... forty ditto	163 ·0
... fifty ditto	181 ·5
... sixty do	196 ·0

ence 3583 cubic inches of this coal-gas raised the temerature of 270 cubic inches of water 148° in an hour.

As the heating power, without regard to the light, must e directly as the temperature communicated, and inverse- as the quantity of gas expended in the same time, the eating power of oil-gas is to that of coal-gas, according to e above experiment, as $\frac{146\cdot5}{3048}$ to $\frac{148}{3583}$, or as 100 to 86.

hen the relative illuminating powers of the gases are so considered, the heating powers seem to be nearly ual, but on the whole greater, in the case of coal-gas, the ratio of about 105 to 100.

4th, *The Safety of using the Gases.*—The explosive force the gases, when they are mixed with various proporns of common air, and the limits within which the exosive range is confined in the case of each gas, may be nsidered under this head.

Among the other delusive statements brought forward th so much confidence in favour of oil-gas, it was even intained, that while coal-gas is capable, when mixed with common air, of producing the most violent explosions, the former was almost exempt from that source of accident. Nor was this absurd and erroneous opinion confined to the ignorant and ill-informed upon the subject; for we find that Sir W. Congreve, in the report which he drew up for the instruction of the British Government, on the state of gas-light establishments in the metropolis, actually affirms in that document, that "the most important feature in the use of oil-gas is its safety; as, from the very narrow limits of the explosive mixture that can be formed of this gas and atmospheric air, it is scarcely possible that an accident can occur." Now, with regard to the limits of explosion thus adverted to, we have found, by the most precise experiments, varied in every conceivable way, that in general one volume of oil-gas will not explode with less than three and a half volumes of common air, nor with more than sixteen volumes; the explosion being most violent when the common air is ten times the volume of the gas; in which case we found that a third part of a cubic inch of oil-gas was capable of displacing with violence a cylindrical mass of iron upwards of forty pounds in weight. One specimen of oil-gas of the specific gravity 1·054, when it was newly prepared, and which, being kept two days, became of the specific gravity ·955, could not be made to explode with less than seven and a half volumes of common air; but it continued to explode till it was mixed with twenty-one volumes, when that effect could no longer be produced. In the case of coal-gas the explosive range was more definite, and less subject to variation in the proportions of its admixture with common air, than oil-gas; the limits being between five and sixteen of common air to one of the gas, almost invariably. The violence of the explosion was also greatly inferior to that of an equal volume of oil-gas, as might readily be inferred from its constitution. And not only are the explosions of oil-gas more formidable than those of coal-gas, but, in consequence of the specific gravity of the former approaching nearer to that of common air, they are, contrary to the assertion of Sir W. Congreve, more likely to occur; so that in both these respects oil-gas must be pronounced to be more dangerous than coal-gas.

Inquiry into the danger attending the use of gas.

As it must be evident from what we have stated, that a considerable degree of danger may be connected with the use of gas, whether obtained from oil or from coal, it may not be improper now to examine a little more in detail the real extent of this evil, in order that, by a due knowledge of the sources from which it is most likely to arise, we may be prepared to guard against its consequences; or, if that be wholly impossible, to enable us at least to judge how far the economy, and other advantages of this mode of obtaining artificial light may be regarded as an adequate compensation, for the risk incurred in adopting it. On this subject, where the safety of the public is so extensively involved, we wish to use the language of caution, but not that of timidity; and while we admit that in a few instances accidents of the most fatal nature have occurred from the use of gas, we hesitate not to affirm that these accidents might generally be traced either to gross ignorance, or culpable negligence, on the part of those who were the victims of them. Accordingly, we find that since the nature of gas has become better known, the accidents from its use are few and trifling. The danger, however, was regarded by the British legislature to be of too serious a nature to be left entirely to the discretion of the manufacturers of gas; and an inquiry into the subject was accordingly instituted in 1814, by order of the Secretary of State for the Home Department. This led to a report from the Royal Society, which was followed by a more minute examination of the subject by Sir William Congreve, who was appointed by Government to prepare a report on the state of the gas-works, in and

The subject taken up by government.

about the metropolis. In this report, which was laid before the public in 1824, Sir William Congreve arranges the dangers from the explosion of gas, as well as those arising from peculiar defects in the construction of the works, under three heads:—

1*st*, That which may occur at the gasometer.

2*dly*, That which may arise after the gas is expelled from the gasometer, in its passage through the main-pipes under the streets.

3*dly*, That which accompanies the use of it in the building where it is consumed.

Danger of explosion, at the gasometer-house.

In considering the chance of explosions occurring at the gasometer-house, he begins with remarking, that, in the first filling of a new gasometer with gas, or in refitting one which, from any cause, may have been emptied, there is no contrivance for "exhausting the atmospheric air;" and accordingly accidents, he states, have actually occurred in the first filling. In proof of this assertion he mentions that "an explosion happened at Manchester, in consequence of the people carrying lights about the gasometer to ascertain if it was air-tight in the act of filling, and very serious mischief ensued. The gasometer was blown to pieces, the house destroyed; one man is said to have been killed, and others severely injured." Now, this source of danger is easily avoided, not by any "contrivance for exhausting the air," but simply by expelling it before the gas is introduced; precisely in the same manner as the gas itself is expelled by the pressure of the gasometer.

The next cause of explosion to which he adverts, is that arising from a gasometer not perfectly air-tight being prevented from sinking by some defect in its chain of suspension. This, however, is a very imaginary case, and so unlikely to happen, that it is quite unnecessary to examine the supposed consequences by which it would be followed, these being of so contingent a nature as to be barely within the range of possibility.

Danger of explosion by lightning.

If the causes of explosion which we have noticed admit of being obviated by a proper construction of the gas apparatus, and a moderate degree of caution on the part of the workmen, there are others which Sir William Congreve has mentioned that are scarcely deserving of any consideration, such as the danger of explosion by lightning, and the chance of the counterpoise of the gasometer falling by the breaking of its suspension-chain. On the first of these sources of danger he remarks, "That it appeared to him such a combustion by lightning or otherwise would produce very destructive effects to the neighbouring buildings and gasometers, merely by the sudden rarefaction and expansion of the air caused by it; and would, in fact, produce a violent detonation and concussion, without supposing any combination of oxygen and hydrogen, but merely by the simple conflagration of the hydrogen." Are we to infer from these observations, that Sir William Congreve thought it possible that hydrogen can undergo any species of conflagration, however "simple," without the presence of oxygen? or did he merely mean to affirm, that if a gasometer were destroyed by lightning, and its contents violently discharged into the air, the dreadful effects would be produced which he describes? As we cannot suppose he entertained the former opinion, we need merely say with respect to the second, that it is not only in the highest degree improbable, but calculated to excite alarm when no reasonable cause for it exists. For, granting that a gasometer were struck by lightning, the electric fluid would either glide silently along its metallic sides to the earth, or, if it penetrated the gas, produce no change on its condition beyond a slight and partial enlargement of its bulk.

With respect to the danger arising from the breaking of the suspension-chain of the gasometer, Sir W. Congreve stated, that the gasometers are made so heavy as to require sometimes a counterpoise of six or seven tons; and he adds, that "if one of these weights should be detached while the gasometer is at work, the pressure of that gasometer on the gas would, on a sudden, be so greatly increased, that the lamps connected with it would immediately flare up to a great height, and in many situations (in shops particularly) set fire to the premises before the lamps could be turned off." This seems to be a most alarming source of danger; and the importance of it weighed so much on the mind of Sir William, that he mentions it in more than one part of his Report. It may be proper, therefore, to examine how far it is calculated to produce the direful consequences which he dreaded from its occurrence. The sudden disengagement of a weight of six or seven tons, with the increase of a corresponding pressure on the gasometer, appears at first sight to be an event likely to be attended with some of the evils, which, it is so confidently stated, would result from it; but the case is quite a hypothetical one; and had Sir W. Congreve reflected for a moment that the pressure of even six or seven tons diffused over a surface of 1200 square feet, would be no more than 550 grains on a square inch, or equal to the pressure of about two inches of water, he never would have introduced into his Report such a groundless cause for alarm. The truth is, that the falling of the counterpoise would increase the pressure upon the gas from three fourths of an inch to perhaps two and a half inches of water; and, by doing so, might excite a little momentary surprise on the part of the consumers of the gas, at the unusual size of their lights; but such an occurrence could not by any means produce the fatal consequences ascribed to it.

The danger to which the community is exposed from the risk of accidents, by the transmissions of the gas through the main-pipes, and its escape from these by leakage, into cellars and other subterraneous places, where it may accumulate in considerable quantity, in admixture with common air, is deserving of more serious examination. It is to this cause, indeed, that we must ascribe the principal accidents that have happened from the use of gas; and the utmost care ought to be taken to guard against their occurrence. The best protection from this source of danger is to be found by trying, with a forcing pump, all the pipes before they are laid, and executing the different joints, where they are connected, with a suitable quantity of lead, and in the most careful manner. When clay can be easily procured, additional security is obtained by beating it well into the tracks after the pipes are laid, so as to surround them with a coating of it to the extent of several inches. This precaution is not only a safeguard against the escape of the gas, but highly conducive to the durability of the pipes.

The last kind of danger to be considered is that which attends the use of gas, through ignorance or negligence, in the building where it is consumed. It has already been stated, that coal-gas will not explode unless it be mixed with more than three, but less than fifteen times its own bulk. If we take the last proportion, being the one from which danger is most to be apprehended in dwelling-houses, it appears that the air of an apartment could not be brought to a state which would place it within the range of explosion, unless it contained a quantity of gas, in admixture with it, equal to one fifteenth part of itself. The most probable way of such a state of things occurring, would be the neglect of turning the stop-cocks of the burners after the extinction of the light. If this were done in an apartment fifteen feet square and ten feet high, and containing therefore 2250 cubic feet, it would require at least 150 cubic feet of gas to be thrown into it before the adulterated air could explode. Now 150 cubic feet of gas would afford a light equal to that of sixty candles ourning for ten hours together,—a quantity of light which, eing ten times more than could ever be required for an partment of the size specified, it may reasonably be conluded, that unless a room were of very small dimensions, nd furnished with more gas burners than necessary, little anger could arise even from the culpable neglect of the top-cocks. At the same time it ought to be noticed, that if he air of a room were undisturbed, it is possible that a imited portion of it, sufficient to occasion a dangerous xplosion, might be brought to a detonating condition in he immediate vicinity of the burner, though the rest of he air in the apartment were not in that state. On the hole, therefore, while we are decidedly of opinion that he risk of using gas is a great deal less than is generally magined, perhaps the best security to the public will be ound to result from an exaggerated representation of its angers. Time, and the experience of its advantages, will radually remove unfounded prejudices against its use, nd ultimately render it the most general, as well as the nost useful and economical, mode of obtaining artificial ght.

5th, *The Economy of Oil and Coal Gas.*—Having exanined at some length the more important of the physical roperties of the two gases, so far as these are connected ith their utility for the purpose of illumination, we shall, stly, consider the relative advantages which they possess a commercial point of view. From a due consideration f these properties, it can scarcely be doubted that, if the wo gases could be procured equally cheap, so as to afford n equal extent and an equal degree of illumination at the ame expense, most people would be disposed to give a reference to oil-gas. The reasons however for doing so re by no means of a kind to supersede the necessity of stituting a comparison between the costs of their prouction; and in this respect, indeed, we shall find reason wonder by what sophistry and misrepresentation oil-gas ould have maintained so long a doubtful competition with al-gas.

Though the results of experiments on a small scale are requently inapplicable to extensive establishments, and, the hands of rash and speculative men, often lay the oundation of ruinous consequences, yet, when examined ith due caution, they are far from being of no value, ut, on the contrary, frequently furnish data from which uch useful information is derived. Thus, we can asertain from experiments on such a scale, what quantity gas is yielded from a particular species of coal, and hat quantity is obtained from a certain kind of oil. rom experiments of that description, it has been found at a pound of cannel coal yields, at an average, from five six cubic feet of gas, and a gallon of whale-oil from ghty to a hundred cubic feet of it; and hence we may fely infer, that sixteen pounds of that species of coal ould produce as much gas as a gallon of whale-oil. ow, sixteen pounds of coal, at 15s. per ton, would cost d.; and therefore, if we reckon the oil at 2s. per gallon, would appear that coal-gas costs little more than one venticth part of an equal volume of oil-gas. It must not inferred, however, from this result, that it would be roportionally more advantageous to employ coal in prerence to oil, for the manufacture of gas; it being possie that the smaller expense of the process of decomposion, and the difference of the illuminating powers of the gases, may compensate, to a certain extent, for so great an inequality in the cost of the materials of production. It will be necessary, therefore, to consider these points in detail, before we can form a true estimate of the relative economy of the two modes of illumination.

Before entering upon this inquiry, it may be proper to mention that a gallon of whale-oil of the specific gravity ·925 weighs almost exactly 53,950 grains. It will be necessary to keep this fact in view, to check the extravagant statements which have been given respecting the number of cubic feet of gas yielded by a gallon of oil, which in some cases have been rated so high that the weight of the gas would have exceeded the weight of the materials from which it was pretended to be derived. On this point we have it in our power to furnish the result of two years' experience, from an exact register of the quantity of gas yielded by the patent apparatus of Taylor and Martineau, at Kinfauns Castle, the residence of Lord Gray, from which it appears to be exactly 70¾ cubic feet. Hence the prime cost of a thousand cubic feet, if the oil were L.25 per ton, would be 28s., independently of the expense of manipulation, and the interest of capital. If we allow it to be only 26s., as stated by the patentees themselves, we shall find that, even on this admission, oil-gas cannot for a moment bear a comparison in point of economy with coal-gas. For if we compare this cost of oil-gas, which, we must remember, is exclusive of the expense of production, with the actual cost of a thousand cubic feet of coal-gas, which at an average may be reckoned 5s. 3d., including every expense of outlay, we shall find the one to bear to the other the ratio of about five to one. But as coal-gas is inferior in illuminating power to oil-gas, in the proportion of 100 to 160, by allowing for this difference of quality, it would appear that the prime cost of coal-gas is less than one third of the cost of the mere oil requisite to yield an equivalent quantity of oil-gas.[1]

The light yielded by oil-gas less than that obtained from oil consumed in the ordinary way

One of the delusive representations respecting oil-gas, by which the public were for a season misled, was, that more light was obtained from oil reduced to the gaseous state, than that substance is capable of yielding when it is burnt in the ordinary way. The incorrectness, however, of this assertion is clearly demonstrated by the following exposition: a gallon of whale-oil consumed with a wick, in a good Argand lamp, we found, by the method of shadows, to yield the light of ten tallow candles for seventy hours, or that of seven hundred candles for one hour. But, according to the statement of Taylor and Martineau, one and a half cubic feet of oil-gas give the light of ten candles for the same time; and therefore a gallon of oil, yielding seventy and three fourths cubic feet, ought to afford the light of 472 candles for an hour. Hence the loss of light by decomposing the oil is in the ratio of 700 to 472, or about thirty-two and a half per cent. This result coincides very nearly with that which we obtain by comparing the weight of the gas with the original weight of the oil, as already stated to be obtained at Lord Gray's gas-work. For the weight of seventy and three fourths cubic feet of oil-gas having the specific gravity ·92 (the average specific gravity we found it to have), ought to be 34,573 grains; and as a gallon of oil weighs 53,950 grains, the loss by decomposition is 19,377 grains, or nearly thirty-six per cent.

It appears from these statements, that while coal is con-

---

[1] At the Perth gas-work it appears, by the result of a year's experience, that 6,179,670 cubic feet of coal-gas are sold for L.2696. s. 9d., being at the rate of nearly 8s. 9d. for a thousand cubic feet, or 14s. for an equivalent quantity of oil-gas. But the cost of e oil which yields that quantity of gas being 26s., it is evident, that without taking into account the expense of the manipulations d interest of capital, a loss of 12s. would be incurred on every 26s. expended for oil, in order to enable oil-gas to be brought into npetition with coal-gas.

Advantages of coal-gas over oil-gas.

verted by its decomposition at a gas-work into a substance greatly more valuable than the material in its original condition, oil is reduced by the same process into one of diminished value; insomuch that the manipulations and the capital expended upon an oil-gas establishment are actually applied to reduce to the extent of thirty per cent. the intrinsic value of the raw material, which, it was pretended, they improve in an equal degree. Add to this, that the loss of gas in the main pipes is found to be fully twenty per cent., and it follows that the light from oil-gas is obtained at twice the expense at which it may be procured immediately from the oil itself.

Hints respecting the Improvement of Coal-Gas.

Of all the combustible bodies having an elementary character, carbon and hydrogen are not only the most widely and copiously diffused throughout the three kingdoms of nature, but best adapted by far for the evolution of light during their combustion. It is only, however, when they are united together in due proportion that they answer the purpose most effectually; and, indeed, in a separate state, their illuminating powers are so feeble, that even when their combustion is accelerated and rendered more perfect by the presence of oxygen, the light they yield is yet unfit for many of the useful ends to which light is subservient. The substances in which carbon and hydrogen are united in the best proportion, for the production of light, are pit-coal in the mineral kingdom, and oils and fatty matter in the animal and vegetable.

The great abundance of coal, and the comparative cheapness at which it can be obtained, give it a decided advantage in point of economy over oleaginous matter, whether of animal or vegetable origin; while the processes of decomposing it, with the view of converting it into a volatile and elastic product, have been so much improved as to render the gas which it yields equally fit for the purpose of illumination with the more costly gases obtained from the oils.

The gas produced by the decomposition of coal and oleaginous matter at a high temperature is a compound of carbon and hydrogen, and consists chiefly of two gases, in which these elementary substances exist in definite proportions. One of these gases is termed carburetted hydrogen, and the other olefiant gas or bicarburetted hydrogen. The former contains one atom of carbon united with two atoms of hydrogen, and the latter an atom of each of these elements.

Light yielded by carburetted hydrogen chiefly derived from the carbon.

Of these two compounds of hydrogen and carbon, that which contains the largest proportion of the latter element is found to yield, during its combustion, the most brilliant light, and that to for a longer period of time. And, indeed, so great is the difference in these respects, that the hydrogen may not improperly be regarded as the mere solvent or vehicle of the carbon, acting the part of wick, and thus presenting that substance in a state sufficiently comminuted for its more perfect combustion. Accordingly, the more abundantly the hydrogen is impregnated with carbon, the greater may we expect to be its illuminating power, and the fitter in every respect for yielding artificial light. These views are fully supported by experiment; for not only is the brilliancy of the light modified by the quantity of carbon held in solution by the hydrogen, but the time which a given portion of the gas takes to consume away by combustion is affected by it in a still greater degree.

To determine in what ratio the illuminating power of the gases obtained both from oil and coal was reduced by diluting them in various proportions with hydrogen, we instituted a series of experiments, the results of which are of considerable importance, inasmuch as they decidedly indicate, not only that the mixture is deteriorated, but that the same quantity of carbonaceous matter yields less light the more largely it is diluted with hydrogen.

Deteri- tion by mixtu with h droge

In the first experiment we took a portion of coal-gas of the specific gravity ·67, which we found consumed at the rate of 4400 cubic inches per hour, and yielded the light of eleven candles, being 400 cubic inches per hour for the light of one candle. This gas being diluted with a fourth part of its bulk of pure hydrogen, acquired the specific gravity ·55, and wasted away at the rate of 6545 cubic inches per hour, yielding the light of ten candles. As a fifth part of the compound gas was hydrogen, the remaining four fifths, amounting to 5236 cubic inches, was the quantity of the coal-gas which, in its diluted state, gave the light of ten candles for an hour; so that 524 cubic inches of the original coal-gas were requisite to give the light of one candle for the same time. But, in its unmixed state, 400 cubic inches were sufficient to give the light of one candle for an hour; and consequently, the deterioration occasioned by the dilution was in the ratio of 524 to 400, or of 100 to 76, being 24 per cent. It must be distinctly kept in view that the deterioration has been reckoned, not with respect to the whole volume of the mixture (in which case it would have been 39 per cent.), but simply in reference to the coal-gas itself, and therefore the experiment, so far as it goes, justifies us in adopting the conclusion, that had the hydrogen existed originally in union with the coal-gas, the latter would have improved in quality 24 per cent. by its abstraction; *because the residuary portion would not only have lasted longer, but yielded during its combustion a superior light.*

In a second experiment, conducted in a similar manner, in which the proportion of hydrogen was one third of the quantity of the coal-gas, the deterioration was 27 per cent.; in a third experiment, the proportion of hydrogen being a half of the volume of the coal-gas, the deterioration amounted to 31 per cent.; and, in a fourth experiment, the quantity of hydrogen being exactly equal to that of the coal-gas, the deterioration extended to 36 per cent.

Genera conclusions.

These results indicate a progressive deterioration in the quality of coal-gas by the admixture of hydrogen; and the important conclusion to which they lead is, that the abstraction or removal of the latter, though diminishing the entire volume, would improve the nature of the residuary portion, not only in a higher ratio than the loss which the whole sustained in its bulk, but render that portion capable of yielding, for a longer period of time, a greater light than it could have done in its original state. Hence it may be inferred that the illuminating power of coal-gas, whether considered with respect to the cost of its production or the intensity of its light, admits of being improved; first, by impregnating the hydrogenous element more largely with carbon; secondly, by preventing the disengagement of hydrogen in a free state during the carbonization of the coal; and lastly, by detaching a portion of that gas from coal-gas when it already exists in admixture with it.

Modes improv coal-gas

The first of these modes of improvement seems to be practicable, at least to a certain extent, by thoroughly drying the coal[1] before it is introduced into the retorts, and modifying the pressure under which the gas is generated. The second, by intermixing with the coal some substance which is at once capable of uniting with the hydrogen, nd of being afterwards detached, in its combined state, rom the coal-gas with which it is mixed. Such a subance is sulphur; and accordingly we find that the coal which sulphur abounds, though it yields an impure gas, et, when duly purified, that gas is of a superior quality what is obtained from coal containing sulphur in more paring quantity. With respect to the third mode of imrovement, we are unfortunately, in the present state of ur knowledge, acquainted with no method of detaching ydrogen from the gases with which it is mixed in oil or oal gas, that would not impair the illuminating power of hese gases, to a greater extent perhaps than the benefit hat would be derived from the removal of the hydrogen.

---

[1] The coal for making gas ought to be kept for several months well protected from moisture before it is used for the purpose. This is a point of the utmost importance in the manufacture of gas.

To determine the diminution of the illuminating power roduced by separating the particles of the inflammable as during its combustion, and thus diminishing the temerature of the flame, it occurred to the writer of the resent article, that nitrogen, neither having the property supporting combustion, nor of adding to the quantity of ombustible matter submitted to that process, was well tted to answer the intended purpose; and accordingly, mixing coal-gas of ordinary quality (which, when burnt one, yielded the light of twelve candles when it conmed 5400 cubic inches per hour) with varying portions nitrogen, results were obtained which implied that the minution of the intensity of the light proceeded in a tio much more rapid, than was observed when the gas as diluted with hydrogen. Thus, when six volumes of e coal-gas were mixed with one volume of nitrogen, the penditure per hour was 6000 cubic inches, and the ht equivalent to that of nine candles, being 667 cubic ches per hour for the light of one candle. But one xth of the whole being nitrogen, the remaining four xths, amounting to 556 cubic inches, was the quantity of e coal-gas, which, in its diluted state, afforded the light a candle for an hour. On the other hand, the quanti- of the coal-gas requisite, in its unadulterated state, to ve an equal degree of illumination, being $\frac{5400}{12}$, or 450 bic inches, it follows that the deterioration was in the tio of 556 to 450, or 100 to 81 nearly.

By diluting the same coal-gas with other proportions of trogen as subjoined, and afterwards applying to each of e results the same kind of reduction, as that which we ve already made, we have deduced the following table, hich exhibits the gradual deterioration of the illuminatg power of the same quantity of coal-gas, produced by e mere separation of the atoms of the gas, during its mbustion.

Volumes of Coal-gas.	Volumes of Nitrogen.	Illuminating Power.
60	0	100
60	10	81
60	12	69
60	15	55
60	20	37
60	30	29
60	60	4

When carbonic acid was used instead of nitrogen, simi- results were obtained; only the deterioration was conlerably greater. Thus, when five volumes of the coals were mixed with one volume of carbonic acid, the ilminating power was reduced from 100 to 30, whereas the case of the nitrogen it was from 100 to 69. It is erefore a fortunate circumstance that carbonic acid, hich is so apt to be generated during the production of al-gas, and has so debasing an influence upon its illunating power, is readily absorbed by a variety of subnces; while nitrogen, the less injurious, as well as the s abundant accompaniment, cannot be separated from e other gases with which it may exist in mixture, by y process yet known.

Deterioration of Gas by keeping it after it is prepared.

Gas-Light.

Both oil and coal gas suffer, by keeping, a gradual loss in their power of illumination, which seems to increase in a more rapid ratio than the time they are kept. The deterioration, though greatest when the gases are allowed to stand over water, takes place in a considerable degree even when they are kept over oil, or in air-tight vessels. Hence it may be presumed that the carbon held in solution by the hydrogen, is separated from that element, partly by its own gravity, and partly perhaps by uniting with the oxygen of a portion of the water over which it is suspended.

Deterioration of oil and coal-gas, when kept over water.

To whatever cause the deterioration is owing, the fact itself is undoubted. Thus, an oil-gas which, when newly prepared, had the specific gravity 1·054, gave the light of a candle for an hour when it consumed 200 cubic inches; kept two days, it gave the same light with a consumpt of 215 cubic inches per hour; and kept four days, it required, for the same light, 240 cubic inches per hour. In the case of a portion of coal-gas, which, when newly prepared, required 404 cubic inches to yield the light of a candle for an hour; the same gas kept two days required 430 cubic inches; and kept four days, 460 cubic inches to yield the same light. These results indicate a progressive deterioration in the quality of the gases, increasing with the length of time they are kept; and it is deserving of remark, that in both gases the diminution of the illuminating power decreases in a faster ratio than the time increases. After being kept three weeks, the oil-gas was so much debased in quality that it required 606 cubic inches of it to yield the light of a candle for an hour; and hence its illuminating power was reduced to one third of what it was when the gas was newly made. From these experiments it may obviously be inferred, that both oil and coal gas should be used as soon as possible after they are prepared.

Economy of Coal-Gas.

Gas superior to other modes of illumination, both in point of economy and convenience.

Among the advantages which have resulted from the introduction of coal-gas, we may reckon, 1*st*, its comparative cheapness; and, 2*dly*, its superiority to all the other modes of artificial illumination.

In forming a comparative estimate of the cost of coal-gas, and that of the other means employed for procuring artificial light, we may contrast it with the expense of wax, tallow, and oil, the ordinary substances used for the purpose. It deserves to be remarked, however, that while the price of coal, in consequence of the regular and abundant supply of that article, is liable to little fluctuation, the cost of wax, tallow, and oil, on account of the more precarious nature of the sources from which they are obtained, varies exceedingly in different seasons. The very extensive use, too, into which coal-gas has been brought, has produced a considerable effect upon the price of oil and tallow, as well as of wax; so that a comparative estimate of the expense of procuring the same extent of illumination from coal-gas and from these substances, must appear less favourable to the former than would have been the case, had the comparison been made when gas was first introduced. But assuming that a pound of tallow candles, which last, when burnt in succession, forty hours, costs ninepence; that a gallon of oil, yielding the light of six hundred candles for an hour, costs two shillings; that the expense of the light from wax is three times as great as from tallow; and that a thousand cubic feet of coal-gas cost nine shillings; we may state the relative cost of the same degree of illumination from these different substances, after making a suitable allowance for waste, wicks, &c. to be as follows:

From wax	100
From tallow	25
From oil	5
From coal-gas	3

But the light obtained from coal-gas is not only procured at a smaller expense; it is also more convenient for most purposes than the light yielded by other substances. In the ordinary mode of lighting by tallow and oil, the light derived from their combustion cannot be diminished in intensity without considerable disadvantage and trouble; whereas, in the case of gas, it may be reduced in an instant from the most perfect splendour to the feeblest degree of illumination, by the simple adjustment of the stop-cock. The advantages arising from this easy method of regulating the light of gas, when it is used in the chambers of the sick, and indeed in all apartments, where a variable, but uninterrupted supply of light must be kept up, can only be duly estimated by those who have experienced them. To every branch of manufacturing industry which requires a steady and powerful light, the benefits which have resulted from the introduction of coal-gas are not less important. In many operations the light may be conveyed by means of flexible pipes, connected together with ball and socket-joints, so as to be almost in contact with the fabric it is intended to illuminate, without the slightest risk of injury; and it may be kept in the same state for many hours in succession, or altered, as circumstances may render necessary.

For lighting churches, theatres, and other public buildings, where a strong and uniform light is required, gas answers the purpose more effectually than any other mode of illumination; partly, from the facility of its application, and partly, from the diversified and tasteful manner, in which the jets of flame may be exhibited in various kinds of burners.

As a street light, its superiority is universally admitted; and from that application of gas it cannot be doubted that the metropolis, and other large towns, have derived great additional security against the perpetration of nocturnal crimes, as well as the means of carrying on the ordinary business of life during the evening, with nearly the same convenience, as during the full light of day. (V. V. V.)

GASCOIGNE, George, an English poet of some name in the early part of the reign of Queen Elizabeth, was born at Walthamstow in Essex, of an ancient family, and educated at both universities, but principally at Cambridge. From thence he removed to Gray's Inn, and commenced student of the law; but having a genius too volatile for that study, he travelled in foreign parts, and for some time served in the army in the Low Countries. He afterwards went to France, where, it is said, he became enamoured of a Scottish lady, and married her. At length being, as Wood says, weary of vanities, he returned to England, and settled once more in Gray's Inn, where he wrote most of his dramatic and other poems. The latter part of his life he spent in his native village of Walthamstow, where he died in the year 1578. He had the character of a polite gentleman, an eloquent and witty companion, *et vir inter poetas sui seculi præstantissimus.* His plays, first printed separately, were afterwards, with several other poems, reprinted in two volumes 4to; the first of which appeared in 1577, the second in 1587.

GASPAR STRAIT, a passage in the Eastern Seas, between the east coast of the island of Banca and the west coast of the island of Billiton, which connects the Java and the China seas. It is about fourteen leagues broad, and is divided in the middle by an island called Middle or Passage Island. There is also an island in the strait, called Gaspar Island, which is about five miles in extent.

GASSENDI, Peter, one of the most celebrated philosophers France has produced, was born at Chantersier, near Digne in Provence, in 1592. When a child, he took particular delight in gazing at the moon and stars as often as they appeared in clear unclouded weather; and the pleasure he thus experienced frequently drew him into bye places, so that his parents had often to seek him, not without many anxious fears and apprehensions. They therefore put him to school at Digne, where, in a short time, he made such extraordinary progress in learning, that some persons who had seen specimens of his genius resolved to have him removed to Aix, in order to study philosophy under Fesaye, a learned Carmelite friar. This proposal was so disagreeable to his father, who intended to breed him up in his own way to country business, that he would consent to it only upon condition that his son should return home in two years at farthest. Accordingly, young Gassendi, at the end of the appointed time, repaired to Chantersier; but he had not been long there when he was invited to become professor of rhetoric at Digne, before he was quite sixteen years of age; and he had been engaged in that office but three years, when his master Fesaye dying, he was made professor in his stead at Aix. When he had been a few years at the latter place, he composed his Paradoxical Exercitations against Aristotle, which having fallen into the hands of Nicholas Peiresc, that great patron of learning joined with Joseph Walter, prior of Valette, in promoting the author; and the latter having entered into holy orders, was first made canon of the church of Digne and doctor of divinity, and then advanced to the wardenship or rectory of that church. Gassendi's fondness for astronomy grew with his years; and as his reputation daily increased, he was in the year 1645 appointed royal professor of mathematics at Paris. This professorship being chiefly designed for astronomy, our author read lectures on that science to a crowded audience. However, he did not hold this place long; for a dangerous cough, accompanied by inflammation of the lungs, obliged him in the year 1647 to return to Digne for the benefit of his native air.

Antiquarian, historian, biographer, natural philosopher, naturalist, astronomer, geometrician, anatomist, preacher, metaphysician, hellenist, dialectician, an erudite scholar, an able critic, and withal an elegant writer, Gassendi ranged through nearly the whole circle of the sciences and arts, at a period when the sciences and arts had been but recently revived; and throughout his laborious and ingenious researches he constantly manifested an excellent spirit. He was the first disciple of Bacon in France, the friend of Galileo and Kepler, the opponent of Descartes, and the precursor of Newton and of Locke. For an eloquent and comprehensive view of his labours and researches as a metaphysician, the reader is referred to the first Dissertation, prefixed to the present work.

The principal works of Gassendi are, 1. Exercitationes Paradoxicæ adversus Aristotelem, Grenoble, 1624; 2. Phænomenon rarum Romæ observatum, Amsterdam and Paris, 1630; 3. Epistolica Dissertatio in qua præcipua principia philosophiæ Roberti Fluddi deteguntur, Paris, 1631; 4. Mercurius in Sole visus et Venus invisa, Paris, 1631; 5. Proportio Gnomonis ad Solstitialem umbram observata, Massiliæ, 1636; 6. Observatio de Septo Cordis pervio, Louvain, 1640; 7. Disquisitio Metaphysica adversus Cartesium, Paris, 1642; 8. De Vita N. Fabr., Paris, 1641; 9. Epist. xx. de apparente magnitudine Solis, Paris, 1641; 10. De Motu impresso a motore translato, Paris, 1649; 11. Novem Stellæ visæ circa Jovem, Paris, 1643; 12. Disquisitio Metaphysica, seu dubitationes et instantia adversus Cartesii Metaphysicam, Amsterdam, 1644; 13. Vita Sancti Dominici primi Diniensis Episcopi, 1644; 14. Oratio inauguralis, Paris, 1645; 15. De Proportione qua gravia decidentia accelerantur, 1646; 16. Apologia adversus J. B. Morinum, Lyons, 1649; 17. De Vita et Moribus Epicuri, libri vii. Lyons, 1647; 18. Institutio Astronomica, Paris, 1647; 19. De Vita, Moribus, et Placitis Epicuri, &c., Lyons, 1649; 20. Syntagma Philosophiæ Epicuri, ibid. 1649; 21. Pièces relatives à la Discussion élevée entre Gassendi et Morin, Paris, 1650; 22. Lettre à Honoré Bouche, historien de Provence, 1652; 23. Joh. Caramuel ad Gassendum, et Fr. Gassendi responsio de infallibilitate Papæ, 1660; 24. Appendix Cometæ, Lyons, 1658; 25. Tychonis Brahæi, Copernici, Purbachii, et Regiomontani vitæ, Paris, 1654; 26. Romanum Calendarium compendiose expositum, ibid. The works of Gassendi have been collected by Montmart and De Sorbière, in the complete edition published at Lyons in 1658, and reprinted at Florence in 1728, in 6 vols. folio, to which are subjoined Syntagma Philosophicum de Gassendi and Commentarii de rebus cœlestibus. Gassendi died at Paris in the year 1658, ged sixty-three.

GASTRIC, in general, something belonging to or connected with the stomach.

GASTRIC *Juice*, a thin pellucid liquor, which distils from ertain glands in the stomach, for the dilution, &c. of the ood.

GASTROMANCY, or GASTROMANTIA, a kind of divination practised amongst the ancients by means of words roceeding or seeming to proceed out of the belly. The ord is Greek, *γαστρομαντεια*, composed of *γαστηρ*, *belly*, and *αντεια*, *divination*. There is another kind of divination lled by the same name, which is performed by means f glasses or other round and transparent vessels, within hich certain figures appear by magic art. It is so called ecause the figures appear as it were in the belly of the essels.

GASTRORAPHY, in *Surgery*, the operation of sewg up wounds of the abdomen.

GASTROTOMY, of *γαστηρ*, and *τεμνω*, *I cut*, the operation of cutting open the belly, otherwise called the *Cæsaan section.*

GATAKER, THOMAS, a learned critic and divine, was orn at London in 1574, and studied at St John's College, ambridge. He was afterwards chosen preacher at Linoln's Inn, a situation which he quitted in 1611 for the rectory of Rotherhithe in Surrey. In 1620 he made a tour rough the Low Countries; and in 1624 he published at ondon a book entitled Transubstantiation declared by e confession of the Popish Writers to have no necessary undation in God's Word, of which he likewise wrote a efence. In 1642 he was appointed one of the assembly divines, and was engaged with them in writing annotaons upon the Bible. He died in July 1654, in the eighth year of his age. Besides the above works, he pubshed, 1. A Dissertation upon the Style of the New Tesment; 2. De Nomine Tetragrammato, in defence of the ode of pronouncing the word Jehovah in England; 3. e Diphthongis, sive Bivocalibus; 4. An Edition and ranslation of Marcus Antoninus's Meditations; 5. A Colction of Sermons in folio; and many other works. His ety and charity were exemplary; and his modesty was so eat, that he declined all ecclesiastical dignities and court eferments. His extensive learning was admired by Salasius and other great men abroad; his house was a prite seminary for young gentlemen of this nation; and any foreigners resorted to him to receive advice in their idies.

GATH, or GETH, a city of the Philistines, and one of eir five principalities. It is celebrated as having given rth to Goliath. David made a conquest of Gath in the beginning of his reign over all Israel; and it continued subject to the kings his successors till the declension and decay of the kingdom of Judah. Rehoboam rebuilt or fortified it, Uzziah retook it, and Hezekiah once more reduced it under his subjection. Gath stood about five or six miles from Jamnia, about fourteen south of Joppa, and thirty-two west of Jerusalem.

GAUBIUS, JEROME-DAVID, professor of medicine at Leyden, and afterwards fellow of the royal society of London, was born at Heidelberg in the year 1705. From the Jesuits he received the rudiments of his education, and was much esteemed by them on account of his abilities; but his father afterwards sent him to the orphanhouse of Halle, lest he should be obliged to abjure his religion. The nature of the discipline, however, he found much too severe, and at his own request his father removed him. His teacher at this hospital attributing the dislike of young Gaubius to the want of genius, urged him to give his son some mechanical employment; but his father thought proper to indulge his ardent desire after knowledge, and accordingly sent him to Amsterdam to study under his uncle John, who was an eminent physician there. After prosecuting his medical studies for some time at Hordwyk, he resolved to visit Leyden, where Boerhaave was then professor, and his penetrating eye soon discovered that Gaubius was possessed of talents above mediocrity. This celebrated man honoured him with unlimited access to his house, delighted in imparting instruction to him, and gradually forwarded the cultivation of his mind. Gaubius took the degree of doctor at the age of twenty, after a disputation on the nature of solids, containing an abstract of the system which he himself subsequently followed in practice. He then travelled through various parts of Europe, and when he returned to Heidelberg by way of Strasburg, he was appointed city physician at Deventer, in the province of Overyssel; but he soon afterwards removed to Amsterdam. Boerhaave never lost sight of his favourite pupil; and when the infirmities of old age and indefatigable labour induced him to resign his chair, Gaubius was upon his recommendation appointed to succeed him. In 1738, he published his *Instructions for Writing Recipes*, which was received with merited approbation, as he had reduced the art from a mechanical into a scientific form. His Principles of Nosology is perhaps his most masterly performance, as it evinced that he was highly worthy of such a preceptor. The next publication of Gaubius, which appeared in 1771, was his *Adversaria varii Argumenti*, a work which was particularly interesting to chemists; and his oration on the two-hundredth anniversary of the academy of Leyden attracted considerable notice, as in it he traced out, with his accustomed acuteness, the principal epochs of the arts and sciences in Holland. He was likewise the author of numerous and valuable papers in the Transactions of the Society of Haerlem, and editor of many excellent performances, amongst which may be mentioned Cramer's *Elementa artis docimasticæ*, Albinus *de presagienda vita et morte*, and Swammerdam's Book of Nature, which he partly translated. His literary merit spread his fame beyond the bounds of his native country, and pupils repaired to Leyden from every part of Europe. In addition to his widely extended reputation, he was blessed with the enjoyment of good health till he attained seventy years of age; and he died on the 29th of November 1780, in his seventy-fifth year. The *Institutiones Pathologiæ Medicinalis* was deemed so valuable by Professor Ackermann, that he published a fourth edition of the work at Nuremberg in 1787.

GAUDEN, JOHN, an English prelate of considerable talents, but of a temporising and interested character, was the son of John Gauden, vicar of Mayfield in Essex, where he was born in the year 1605. Having received the rudiments of his education at Bury St Edmund's in Suffolk, he was removed to St John's College, Cambridge, where he made considerable proficiency in learning, and took his degree in arts. About 1630 he was presented to the vicarage of Chippenham in Cambridgeshire, and he also obtained the rectory of Brightwell in Berkshire. This last preferment having brought him near Oxford, he entered himself of Wadham College in that university, and became tutor to some noblemen and several young gentlemen who were placed under his care. In 1635, he took his degree as bachelor in divinity, and in 1641 he was received as doctor in the theological faculty. At the commencement of the civil war he had become chaplain to the Earl of Warwick, a Presbyterian leader; and having ranged himself on the same side as his patron, he, in the end of November, after the close imprisonment of Lord Strafford, preached a sermon before the House of Commons, which proved so agreeable to that assembly, that it is said they presented him with a large silver tankard, bearing the inscription, *Donum honorarium populi Anglicani in Parliamento congregati, Johanni Gauden;* a token of their esteem, which, if the story be true, may seem to be the stronger for its singularity and unseemliness.[1] His discourse seems to have consisted of an invective against the ecclesiastical policy of the court; and it was not only preached at a critical time, but on the solemn occasion of the sacrament being first taken by the whole house. As a reward for so conspicuous a service to the parliamentary cause, he soon afterwards received the valuable living of Bocking in Essex, which he held through all the succeeding changes of government; forbearing of necessity to use the liturgy, and complying with all the conditions which the law then required from the beneficed clergy. He was also chosen one of the assembly of divines who met at Westminster in 1643; but it has been disputed whether he took the covenant, though his own evasive answers seem rather to confirm the opinion that he had. It is said that he wrote a *Protestation* against the trial of the king in 1648, and likewise an *Invective* against those of the army and their abettors who murdered Charles I.; but neither of these pieces was published until two years after the Restoration; and even if the former had appeared at the needful time, it would have been disregarded, seeing that the solemn declaration of all the Presbyterian clergy of London against bringing Charles to trial had proved unavailing.

But the most remarkable production with which the name of Gauden has been connected is the famous Εικων Βασιλικη, or Portraiture of his Sacred Majesty in his Solitude and Sufferings, which appeared after the execution of Charles I., and in the course of a year passed through fifty editions. The *Eikon Basiliké* seems to have been intended to produce a favourable effect during the king's trial; but its publication was retarded until some days after his death, by the jealous and rigorous precautions adopted by the regicides. The impression made on the public by a work which purported to convey the pious and eloquent language of a dying king could not fail to be very considerable; and though its genuineness was from the beginning doubted or disbelieved by some, including Milton, Goodwyn, and Lilly, yet unbounded faith in its authenticity as the production of Charles himself soon became one of the fundamental articles of the royalist creed. At the Restoration, Gauden was promoted to the see of Exeter, whence he was in 1662 translated to that of Worcester. But he was so far from being satisfied with this promotion, that he looked upon it as an act of injustice. He had, it appears, applied to the king for the rich bishopric of Winchester, which he flattered himself with the hopes of obtaining; and, when he failed, the vexation he suffered on account of this disappointment is believed to have hastened his death, which took place on the 20th of September 1662. Gauden was the author of many controversial pieces, suited to the temper of the times, and to his own views, which were always those of a selfish and temporising divine.

The question, Who wrote the *Eikon Basiliké?* which Gauden published as King Charles's private meditations, has, as our readers must be aware, been long agitated; but the controversy seems at length to have been ended by a verdict upon the whole case in favour of Gauden as the author. At the moment of the Restoration, this complying person, who had thundered before the parliament against the ecclesiastical policy of the court, appears to have had as little *public* claim on the favour of Charles II. as any clergyman who had conformed to the religious principles of the parliament and the protectorate; and he was accordingly stigmatized by some zealous royalists as "the false apostate." He was sufficiently a Presbyterian in party to make him no favourite with the court; yet he was not so decided a Presbyterian in principle as to have that influence amongst his party which could make him worth so high a price as a mitre. Those who dispute his claim to be acknowledged as the writer of the *Eikon,* will not ascribe his preferment to transcendent abilities; he is not mentioned as having ever shown kindness to the royalists; there is no trace of his having corresponded with the exiled court; he contributed nothing to the recall of the king, nor indeed had he the power of performing such atoning services. Yet, though thus without the shadow of a claim to preferment on any *public* ground, and indeed one of the last persons whom the court might be supposed to have been inclined to promote, Gauden was, nevertheless, on the 3d of November 1660, appointed Bishop of Exeter, and, in a few months, he received no less than L.20,000 for the renewal of leases. Nor was he at all satisfied with this advancement. In fact, he had scarcely arrived at his episcopal palace, when, on the 21st of December, he wrote a letter to Lord Chancellor Clarendon, complaining bitterly of the "distress, infelicity, and horror" of such a bishopric, and lamenting "a hard fate which," he reminds the chancellor, he "had before deprecated." "I am not so unconscious," he adds, "to *the service done to the church and to his Majesty's family,* as to bear with patience the ruin heaped on me. Are these the effects of his liberal expressions, who told me I might have what I would desire?" Five days afterwards (26th December 1660) he wrote another letter, in which he says, "Dr Morley once offered me my option, *upon account of some service which he thought I had done extraordinary for the church and royal family,* of which he told me *your Lordship was informed.*" Gauden appears soon afterwards to have written to Sir E. Nicholas, secretary of state, a letter expressed so as to be read by the king; and on the 19th January 1661, he received an answer, in which there is the following sentence: "As for your own particular, he (the king) desires you not to be discouraged at the poverty of your bishopric at present, and if that answer not the expense that was *promised* you, *his Majesty will take you so particularly into his care,* that he bids me assure you shall have no cause to remember Bocking." On the 21st of January the importunate prelate again addressed to Clarendon a letter explicitly stating the nature of the services, which was probably rendered necessary, in his opinion, by the continued silence of the chancellor, and distinctly claiming "what goes under the late blessed king's name, the Εἰκων *or Portraiture of hys Majesty in hys Solitudes and Sufferings*," as his own production. "This book and figure," he says, "*was wholly and only my invention, making, and designe*, in order to vindicate the king's wisdome, honor, and piety. My wife indeed was conscious to it, and had an hand in *disguising the letters of that copy which I sent to the king in he Isle of Wight* by favour of the late Marquise of Hertord, which was delivered to the king by the now Bishop of Winchester (Duppa): hys majesty graciously accepted, wned, and adopted it as hys sense and genius, not only vith great approbation, but admiration. Hee kept it with ym; and though hys cruel murtherers went on to perfect ys martyrdome, yet God preserved and prospered the ook to revive hys honor, and to redeeme hys majesty's ame from that grave of contempt and abhorrence or inamy, in which they aymed to bring hym." The bishop vrote three more letters to Clarendon on the 25th Janary, the 20th February, and the 6th March; and, at last, he chancellor replied to his numerous applications in a etter dated the 13th of March 1661, in which Gauden's laim is unequivocally admitted. After many apologies or delay, and professions of good will towards his imporunate correspondent, Clarendon says, "*The particular hich you often renewed, I do confesse was imparted to me nder secrecy, and of which I did not take myself to be t liberty to take notice, and truly*, WHEN IT CEASES TO E A SECRET, *I know nobody will be gladd of it but Mr Ilton; I have very often wished I had never been trusted ith it.*"

---

[1] The journals make no mention of the tankard, but bear "that the thanks of this house be given to *Mr Gaudy* and Mr Morley for their sermons last Sunday, and that they be desired, if they please, to print the same." (*Com. Journ.* ii. 40.)

Now this, taken in conjunction with Gauden's immeiate promotion to the episcopal dignity after the Restoraon, and the letter of the secretary of state, Sir E. Nichos, above referred to, appears to us to be decisive of the hole question as to the authorship of the *Eikon*. "It proper to remark here," says Sir James Mackintosh,[1] that all the letters of Gauden are still extant, indorsed y Lord Clarendon, or by his eldest son. In the course three months, then, it appears that Gauden, with unsual importunity and confidence, with complaints which ere disguised reproaches, and sometimes with an aproach to menaces, asserted his claim to be richly reward-l *as the author of the Eikon*. He affirms that it was sent the king by the Duke of Somerset, who died about a onth before his first letter, and delivered to his majesty y Dr Duppa, bishop of Winchester, who was still alive. e adds, that he had acquainted Charles II. with the seet through the Duke of York; that Morley, then bishop Worcester, had informed Clarendon of it; and that orley himself had declared the value of the service to such as to entitle Gauden to chuse his own preferment. auden thus enabled Clarendon to convict him of falseod, if his tale was untrue, in three or four circumstans, differing indeed in their importance as to the main estion, but equally material to his own veracity. A gle word from Duppa would have overwhelmed him th infamy. Some of the communications were made fore the Duke of Somerset's death, on the 24th of Ocber. How easy was it for the chancellor to ascertain ether the information had been given to the king and s brother! Morley was his bosom friend, and the spirial director of his daughter Anne, duchess of York. How ny other persons might have been quietly sounded by e numerous confidential agents of a great minister, on a nsaction which had occurred only twelve years before! suppose that a statesman then at the zenith of his eatness could not discover the truth on this subject without a noise like a judicial inquiry, would betray a singular ignorance of affairs. Did Clarendon relinquish without a struggle his belief in a book which had doubtless touched his feelings when he read it as the work of his royal master? Even curiosity might have led Charles II., when receiving the blessing of Duppa on his (Duppa's) deathbed, to ask him a short confidential question. To how many chances of detection did Gauden expose himself? How nearly impossible is it that the king, the duke, the chancellor, and Morley, should have abstained from the safest means of inquiry, and, in opposition to their former opinions and prejudices, yielded at once to Gauden's assertion, without any evidence of its truth?"

Sir James Mackintosh then goes on to show, that the previous belief of the royalist party in the genuineness of the *Eikon* very much magnifies the improbability of such suppositions. "The truth," says he, "might be discovered from the parties appealed to, and conveyed to the audacious pretender without any scandal. There was no need of any public exposure. A private intimation of the falsehood of one material circumstance must have silenced Gauden. But what, on the contrary, is the answer of Lord Clarendon? The decisive words, at length extorted from him, 'When it ceases to be a secret, I know nobody will be glad of it but Mr Milton,' express such an unhesitating assent to the claim as could only have flowed from inquiry and evidence. By confessing that the secret had been imparted to him, he admits the other material part of Gauden's statement, that the information came through Morley. It may also be remarked, that Gauden, if his story was true, chose the persons to whom he imparted it both prudently and fairly. He dealt with it as a secret the disclosure of which would injure the royal cause; and he therefore confined his communications to the king's sons and the chancellor, who could not be indisposed to the cause by it, and whose knowledge of it was necessary to justify his own legitimate claims. Had it been false, no choice could have been more unfortunate. He appealed to those who, for ought he knew, might have in their possession the means of instantly demonstrating that he was guilty of a falsehood so impudent and perilous that nothing parallel to it has ever been hazarded by a man of sound mind. How could Gauden know that the king did not possess his father's manuscript, and that Royston the printer was not ready to prove that he received it from Charles I. through hands totally unconnected with Gauden?"

This reasoning seems to be quite decisive; but as the case is argued on every point in the masterly article to which we have already alluded; and as the objections which have from time to time been raised against Gauden's claim are there victoriously refuted, whilst the peculiar character of the book itself is shown to be such as to destroy all probability of its being the composition of Charles I.; we shall content ourselves with referring the reader to the *Edinburgh Review*, vol. xliv. p. 2, *et seqq.* taken in conjunction with Dr Wordsworth's book entitled *Who wrote Icon Basiliké*, Cambridge, 1824.

GAUGING. See MENSURATION.

GAUGING-Rod, an instrument used in gauging or measuring the contents of any vessel. That usually employed is the four-foot gauging rod. It is commonly made of box, and consists of four rules, each a foot long, and about three eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long when the four rules are quite opened, and but one foot when they are all folded together.

GAUKARNA, a town of Hindustan, in the province of

---

[1] *Edinburgh Review*, vol. xliv. p. 15.

North Canara. It consists of five hundred houses, interspersed with cocoa-nut trees; and has a temple dedicated to Mahadeva. Salt is made in the neighbourhood; but it is of bad quality, and is scarcely saleable. Long. 74. 25. E. Lat. 14. 32. N.

GAUL, an extensive country in the west of Europe, the boundaries of which in the later times of the Romans were, on the west the Atlantic, on the north the German Ocean, on the east the river Rhine and Alps, and on the south the Mediterranean and Pyrenees.

To the earliest writers we find no part of this country known, except a small portion to the south along the coast of the Mediterranean, and at that time it seems to have had no general name. The tribes on the coast were Bebryces and Ligures, and in the interior they only knew that the people were called Celtæ. The extent of their kingdom, and the shape of their land, remained perfectly unknown to the Greeks. Through Pytheas (about 334, B. C.) they first discovered that it was bounded to the north by the ocean, and that the inhabitants in the interior resembled each other in their manner of living. They therefore concluded that the Celtæ extended over the whole of the north-western portion of Europe. It was not till the conclusion of the second Punic war (201, B. C.) that the Romans began to acquire a firm footing in the south of Gaul, and thereby to obtain somewhat more accurate information respecting the interior. Scipio the elder discovered that there was a river Liger, *Loire*, in the country, and a commercial city of the Celtæ situated upon it. Still their knowledge was confined to a few scanty facts, and it was the Gallic wars of Cæsar which at last enabled them to form a correct idea of the country. They saw that the river Rhine separated the Celtæ from a perfectly different people, the Germani, and they became acquainted with the Belgæ, formed by a mixture of the two, and whose name they had never before heard. From this period no province of the kingdom became better known, nor more frequently travelled through, than Gallia, on account of the wars with the Germani, and its proximity to Britain.

Gaul was inhabited by four tribes, dissimilar to each other both in language and customs. The Aquitani, of Iberian origin; the Ligures, dwelling from the foot of the Pyrenees along the coast as far as the river Arno in Italy; the Belgæ, of Germanic and Celtic origin; and the Celtæ or Galli in the Roman language, who may be considered as the principal nation in the country. Their possessions extended from the extremities of Bretagne, through the whole country lying between the Seine and Garonne, as far as the Rhine and the Alps. There seems every reason to believe that these Celtæ came from the east, along the banks of the Danube; at least we find them in the very earliest ages settled in the south of Germany, and in the greater part of Hungary. That their occupation of Gaul must have taken place at an early period, is proved by the immigration of large bodies into Italy in the reign of Tarquinius Priscus (616–578, B. C.).

Before the time of Cæsar, the Celts lived throughout the country, divided into a number of small tribes, having each an aristocratic constitution, such as Poland once enjoyed. There was no king over the whole; but in many of the tribes we find a prince at their head. Every thing was transacted in the national assemblies, where the nobles only had a place. The lower orders seem to have been regarded in not much better light than slaves. In a country possessed by so many independent tribes, there must of course have been continual disputes; and scarcely a year passed without war. The less strong united themselves to their more powerful neighbours, and made common cause with them in their wars. The whole power seems to have been generally in the hands of the nobility, who had regular guards to protect their persons and dignity. All ancient writers speak of the strange mixture of excessive levity in the character of the Celts with foolhardiness and timidity. They were of a slender form, robust, furious in the first assault, but unable to persevere when fatigue and hardships were to be endured.

In the reign of Augustus, Gallia was first divided into regular provinces by Agrippa. These were Aquitanica, Belgica, Lugdunensis, and Provincia Romana, or Narbonensis. The inhabitants led a quiet and peaceful life under the dominion of the Romans, though they occasionally broke out in rebellion, which was generally caused by the oppression of the tax-gatherers and governors. Julius Vindex, a noble of Gaul, made an attempt in the reign of Nero to free his country from a foreign yoke; but though he managed to collect an army of a hundred thousand men, they were easily defeated by the disciplined troops of the Romans. The rebellion of the Batavi, and of the German and Belgic tribes, threatened more danger at a later period; but it was put down partly by force and partly by conciliatory measures. The inhabitants of Gaul continued to cultivate their fields in peace till the end of the second and third centuries, when the Francs and Alemanni began to make incursions into their territory. See FRANCE.

GAUNGRA, a district belonging to the Nagpoor Mahrattas, in the province of Berar, situated about the twenty-second degree of north latitude. The country is mountainous, and is intersected by the Japtee river; but very little is known respecting it.

GAUZE, in *Commerce*, a very thin, slight, transparent kind of stuff, woven sometimes of silk, and sometimes only of thread. To warp the silk for making gauze, a peculiar kind of mill is used, upon which the silk is wound. This mill is a wooden machine, about six feet high, having an axis placed perpendicularly in the middle, with six large wings, on which the silk is wound from off the bobbins by the axis turning round. When all the silk is on the mill, another instrument is used to wind it off again upon two beams; and this being done, the silk is passed through as many little beads as there are threads of silk, and thus rolled upon another beam to supply the loom. The gauze loom is much like that of the common weavers, though it has several appendages peculiar to itself.

GAVEL, in *Law*, tribute, toll, custom, or yearly revenue; of which we had in old time several kinds.

Gavel-Kind, a tenure or custom belonging to lands in the county of Kent. The word is said by Lambard to be compounded of three Saxon words, *gyfe*, *eal*, *kyn*, or *omnibus cognatione proximis data*. Verstegan calls it *gavelkind*, or give all kind, that is, to each child his part; and Taylor, in his history of *gavelkind*, derives it from the British *gavel*, that is, a hold or tenure, and *cenned*, *generatio* or *familia*; and so *gavel cenned* might signify *tenura generationis*. It is universally known what struggles the Kentish men made to preserve their ancient liberties, and with how much success those struggles were attended. And as it is principally here that we meet with the custom of gavelkind, though it was and is to be found in some other parts of the kingdom, we may fairly conclude that this was a part of these liberties; agreeably to Mr Selden's opinion, that gavelkind, before the Norman conquest, was the general custom of the realm. The principal and distinguishing properties of this kind of tenure are these: 1. The tenant is of age sufficient to alienate his estate by feoffment, at the age of fifteen. 2. The estate does not escheat in case of an attainder and execution for felony; their maxim being, "the father to the bough, the son to the plough." 3. In most places, he had the power of devising lands by will, before the statute for that purpose was made. 4. The lands descend, not to the oldest, youngest, or any one son only, but to all the sons together; which was indeed aniently the most usual course of descent all over England, hough in particular places particular customs prevailed.

GAVOTTA, or Gavotte, is a kind of dance, the air f which has two brisk and lively strains in common time, ach of which strains is twice played over. The first has sually four or eight bars; and the second contains eight, welve, or more. The first begins with a minim, or two rotchets, or notes of equal value, and the hand rising; nd it ends with the fall of the hand upon the dominant mediant of the mode, but never upon the final, unless be a rondeau. The last begins with the rise of the and, and ends with the fall upon the final of the mode.

Tempi di Gavotta, is when only the time or movement a gavotte is imitated, without any regard to the measures or number of bars or strains. Little airs are often und in sonatas, which have this phrase to regulate their otions.

GAWELGUR, a strong fortress of Hindustan, in the rovince of Berar. Its situation is elevated on a high and cky hill between the Poornah and Taptee rivers. It onsists of a citadel with an inner fort, which fronts the orth, where the rock is most inaccessible; and the citadel defended by an outer fort, and both are very strongly rtified, and the ascent by the road is very long and eep, and well defended. Notwithstanding these strong efences, it was taken by the army under General Welsley, on the 14th of December 1803, after a siege of nly two days, and was restored to the rajah on the conusion of the peace. Gawelgur is thirty-two miles northorth-west from Ellichpoor. Long. 77. 52. E. Lat. 21. 46. N.

GAY, John, a celebrated English poet, descended from n ancient family in Devonshire, was born at Exeter, and eceived his education at the free school of Barnstaple in hat county, under the care of Mr William Rayner. He as bred as a mercer in the Strand; but having a small rtune, independently of business, and considering the tendance on a shop as a degradation of those talents hich he knew himself to be possessed of, he quitted that ccupation, and applied himself to other pursuits, including the indulgence of his inclination for poetry. In 1712 e find him secretary, or rather domestic steward, to the uchess of Monmouth, a station in which he continued ntil the beginning of the year 1714, when he accompanied he Earl of Clarendon to Hanover, whither that nobleman was dispatched by Queen Anne. At the close of the ame year, the queen's death recalled him to England, here he lived in the highest estimation and intimacy of iendship with many persons of the first distinction in oint both of rank and abilities. He was even particular- noticed by Queen Caroline, then princess of Wales, to hom he had the honour of reading in manuscript his tragedy of the *Captives*; and in 1726 he dedicated his *Fables*, y permission, to the Duke of Cumberland. From the ountenance thus shown to him, and numberless promises ade him of preferment, it was reasonable to suppose, hat he would have been provided for in some office suitd to his inclination and abilities. But instead of this, in 727, he was offered the place of gentleman usher to one f the young princesses; an office which, looking on it as n indignity to a man whose talents might have been so uch better employed, he thought proper to refuse; and ome pretty warm remonstrances were made on the occaion by the Duke and Duchess of Queensberry, his sincere iends and zealous patrons, which terminated in these two oble personages withdrawing from court in disgust. Mr ay's dependence on the promises of the great, and the isappointments he met with, he has figuratively describd in his fable of the *Hare with many Friends*. However, he extraordinary success which he met with from the pubc made ample amends both in respect to satisfaction and molument; for in the season of 1727–28 appeared his *Beggar's Opera*, the success of which was not only unprecedented, but almost incredible. It had an uninterrupted run in London of sixty-three nights in the first season, and was renewed in the ensuing one with equal approbation. It spread into all the great towns of England; it was played in many places to the thirtieth and fortieth, and at Bath and Bristol to the fiftieth time; it made its progress into Wales, Scotland, and Ireland, in which last country it was acted for twenty-four successive nights; and it was even performed at the island of Minorca. Nor was the fame of this opera confined to the reading and representation alone, for the card-table and drawing-room shared with the theatre and closet in this respect; the ladies carried about the favourite songs of the piece engraven upon their fans; and screens and other pieces of furniture were decorated with designs from it. In short, the satire of this production was so striking, so apparent, and so perfectly adapted to the taste of all degrees of people, that it overthrew the Italian opera, that dagon of the nobility and gentry, which had so long seduced them to idolatry, and which Dennis by the labours and outcries of a whole life, and many other writers by the force of reason and reflection, had in vain endeavoured to drive from the throne of public taste. The profits of this piece were so very great, both to the author and the manager Mr Rich, that it gave rise to a quibble, which became frequent in the mouths of many, namely, that it had made Rich gay, and Gay rich. It has been asserted, indeed, that the author's own emoluments from it were not less than L.2000. This success induced Mr Gay to write a second part, which he entitled *Polly*. But the disgust subsisting between him and the court, together with the misrepresentations made of him as having been the author of some disaffected libels and seditious pamphlets, occasioned a prohibition and suppression of it to be sent from the lord chamberlain, at the very time when every thing was in readiness for the rehearsal of the piece. A very considerable sum, however, accrued to the author from the publication of it afterwards in quarto. Mr Gay wrote several other pieces in the dramatic line, and many valuable compositions in verse. Amongst the latter, his *Trivia, or the art of Walking the Streets of London*, though his first poetical attempt, is far from being the least considerable, and is what recommended him to the esteem and friendship of Mr Pope. But as, among his dramatic works, his Beggar's Opera did at first, and perhaps ever will, stand as an unrivalled masterpiece, so, among his poetical works, his Fables hold the same degree of estimation; the latter having been almost as universally read as the former was represented, and both equally admired. Mr Gay's disposition was sweet and affable, his temper generous, and his conversation agreeable and entertaining. But he had one foible, too frequently incident to men of literary abilities, and which subjected him at times to inconveniences which otherwise he might have avoided, namely, an excess of indolence, without any knowledge of economy. Hence, although his emoluments were, at some periods of his life, very considerable, he was at others greatly straitened in his circumstances; nor could he prevail on himself to follow the advice of his friend Dean Swift, whom we find in many of his letters endeavouring to persuade him to purchase an annuity as a reserve for the exigencies of old age. Mr Gay chose rather to throw himself on patronage, than secure to himself an independent competency by the means pointed out to him; and hence, after having undergone many vicissitudes of fortune, and being for some time chiefly supported by the liberality of the Duke and Duchess of Queensberry, he died at their house in Burlington Gardens, in December 1732. He was interred in Westminster Abbey, and a monument erected to his memory, at the expense of his noble benefactors, with an inscription expressive of their regards and his own deserts, and an epitaph in verse by Mr Pope.

GAYA, a small island in the Eastern Seas, on the north-west coast of Borneo. It is six or eight miles in circumference; and there are many smaller islets in the vicinity. Long. 116. 2. E. Lat. 7. N.

GAYAH, or Boodh Gayah, a town of Hindustan, in the province of Bahar. It is one of the most celebrated places of Hindu pilgrimage, having been the birthplace of Boodh or Buddha, one of the supposed incarnations of the Deity. Many extraordinary ceremonies are performed here by those who frequent the sacred spot. Amongst these, many of the female pilgrims, especially widows, are in the practice of shaving their hair, and devoting themselves from that time to a life of sanctity. The whole business is under the superintendence of Brahmins, who permit any person to enter the temple and approach the idol, which is that of a man sitting cross-legged, and so very rudely carved as to indicate a very remote antiquity. The Bengal government derive from the resort of pilgrims to this sacred place an annual revenue of L.16,000. Long. 85. 5. E. Lat. 24. 49. N

GAZA, or Gazis, Theodore, born at Thessalonica, now Salonica, a famous Greek, who came to reside in Italy after the capture of his native city by the Turks in 1429. After having professed Greek at Sienna, Gaza repaired to Ferrara, on the invitation of the duke, and founded in that city an academy, of which he was the first rector. He taught Greek there for several years, and with so much success, that when he had quitted Ferrara to go to Rome, whither he was called by Pope Nicolas V., it became the usage among the friends of Greek literature not to pass before the house which he had occupied without uncovering; and this usage subsisted long after his death. It was about 1455 that Gaza proceeded to Rome. He knew perfectly the Latin, which he had studied under Victorio de Feltre; and the pope wished to employ him in translating into that language some of the best Greek authors. The translation of the Problems of Aristotle, which he undertook, produced a quarrel between him and George of Trebizond, who had already translated them; but it procured him the esteem and protection of Cardinal Bessarion. He also translated the Problems of Alexander of Aphrodisus, the Tactics of Ælian, the Treatise on Composition by Dionysius of Halicarnassus, the five Homilies of St John Chrysostom on the incomprehensible nature of God, the History of Animals by Aristotle (Venice, 1476, in fol.), and that of Plants by Theophrastus (Paris, 1529, in 8vo). The two last translations formed the principal occupation of his latter years. They have been frequently reprinted; but the estimation in which they were once held has been considerably diminished. Gaza translated into Greek two works of Cicero, the Treatise on Old Age, and the Dream of Scipio; versions which, though now forgotten, were formerly in great request, if at least we may judge from the number of editions. Amongst the original productions of Gaza will always be distinguished his Greek Grammar, in four books; an excellent work, and very often printed either in whole or in part. It is written in Greek; but Erasmus has translated into Latin the first two books, and other learned men, Heresbach, Tusanus, Crocus, and Elias André, have completed the translation, and illustrated it by remarks. The Greeks attach the greatest value to this grammar. In 1768, the deacon Neophytus published at Bucharest, where he was professor of Greek, an immense commentary of 1298 pages in folio on the fourth book alone; and more recently, in 1780, Daniel Keramefs, a monk of Patmos, and professor of Greek in the gymnasium of that island, caused to be printed at Venice another commentary on the same book. Gaza is also author of a Greek Letter to Philelphus, on the origin of the Turks, printed with the Latin translation of Sebastian Casteillon, in the History of the Turks by Chalcondylas, Bâle, 1556, and with the version of Leo Alacci in his *Symmicta*, Cologne, 1653; of a paraphrase in Greek of the *Batrachomyomachia*, published not many years ago, by Fontani, from a manuscript of Florence; and of a Treatise on the ancient months, which Perellus has translated into Latin, and of which there have been several editions, amongst others that of Paris, 1530, in 8vo. In Fabricius, in Hodius (*de Græcis Illustribus*), and in the Bœrner, the reader will find the titles of the unedited works of Gaza. What has not been printed of his is of so little importance that it is doubtful if any one will ever think of publishing them. His commentary on the Delineations of Philostratus appears, however, to merit more attention, although it is not improbable that he who should give himself the trouble of searching for and examining it, would only find *scholia* of but little importance. Theodore Gaza died in 1478, in possession of a benefice in the Abbruzzi, which he had obtained by the favour of Cardinal Bessarion. (A.)

Gaza, a principal city, and one of the five satrapies of the Philistines. It was situated about a hundred stadia from the Mediterranean, on an artificial mount, and strongly walled round. It was destroyed by Alexander the Great, and afterwards by Antiochus. Gaza is now only a large village, and is divided into two parts, called Upper and Lower, both of which, taken together, are designated Gazara. There is here, however, a considerable manufacture of cotton, and great quantities of ashes for making soap are also prepared.

GAZETTE, a newspaper, or account of the transactions of all the countries in the world, printed on a loose sheet or half sheet. This name is with us confined to that paper of news published by authority. The word is derived from *gazetta*, a Venetian coin, which was the usual price of the first newspaper printed there, and which was afterwards given to the paper itself. The first gazette in England was published at Oxford, whilst the court resided there, in a folio sheet, dated 7th November 1665. On the removal of the court to London the title was changed to that of the *London Gazette*.

GAZNA, a city of Asia, once much celebrated, and the capital of a very extensive empire. It was taken by the Moguls in the year 1222.

GAZYPOOR, a district of Hindustan, in the province of Allahabad, and zemindary of Benares, situated about the 26th degree of north latitude. It is bounded on the north and east by the river Goggrah, on the south by the Ganges, and on the west by the district of Joanpore. It is one of the most fertile districts in India, remarkably well supplied with water; and has also been long celebrated for its otto of roses and rose water. Besides grain of all kinds, it produces cotton and sugar, as well as opium, and very fine indigo. It also supplies an investment of calicoes. The chief towns are Gazypoor, Azimpoor, and Dooryghaut.

Gazypoor, a town of Hindustan, in the province of Allahabad, and capital of the above district. It is situated on the bank of the Ganges, and contains a palace and a handsome mosque. In its vicinity are extensive cantonments for three regiments of cavalry. Long. 83. 33. E. Lat. 25. 35. N.

GEBY, or Gibby, an island in the Eastern Seas, surrounded by a cluster of smaller isles. It is situated in the passage between the islands of Waygoo and Gilolo, on the equinoctial line. It is about twenty-five miles long by three broad, and lies between the 129th and the 130th degrees of east longitude. It is little known in the interior. The rise of the tides here, even at spring tide, is only five feet.

GEBY ZEH, or Gebsa, a small town of Asia Minor, supposed to be the ancient Lybissa, where there is a mount, reported to be the tomb of Hannibal. Twenty-five miles east-south-east of Seutari.

GED, William, an ingenious though unsuccessful artist (a goldsmith in Edinburgh), who deserves to be noticed on account of his attempt to introduce an improvement in the art of printing. The invention, first practised by Ged in 1725, may be shortly described. From any types of Greek, Roman, or other character, he formed a plate for every age, or sheet, of a book, from which he printed, instead f using a type for every letter, as is done in the common way. This was first practised, but on blocks of wood, by he Chinese and Japanese, and pursued in the first essays f Coster. "This improvement," says James Ged, the inentor's son, "is principally considerable in three most imortant articles, viz. expense, correctness, beauty, and uniormity." In July 1729, William Ged entered into partership with William Fenner, a London stationer, who was o receive half the profits, in consideration of his advancing ll the money requisite. To supply this, Mr John James, hen an architect at Greenwich, was taken into the scheme, nd afterwards his brother Mr Thomas James, a letter-ounder, and James Ged, the inventor's son. In 1730, hese partners applied to the university of Cambridge for he printing of Bibles and common prayer books by blocks stead of single types; and, in consequence, a lease was ealed to them, on the 23d April 1731. In this attempt ey invested a large sum of money, and finished only two rayer books, when it had to be relinquished, and the ase was afterwards given up. Ged imputed his disapointment to the villany of the pressmen, and the ill treatent of his partners, particularly Fenner, whom John James nd he were advised to prosecute, but declined it. He turned to Scotland in 1736, where he gave his friends a ecimen of his performance, by an edition of Sallust inted according to his method, *tabellis seu laminis fusis.* ut being still unsuccessful, and having failed in obtaining dress from Fenner, who died insolvent, he was preparing ain to set out for London, in order to join with his son mes as a printer there, when he died, on the 19th Octoer 1749. The date of his birth is unknown.

GEDDES, Alexander, a learned Scotch Catholic dine and eminent biblical critic, was born in the parish of uthven in Banffshire, in the year 1737. His parents ere respectable, although not opulent. His father was a rmer, who deemed no trouble too great in order to procure for his children as liberal an education as possible. oth father and mother were of the Catholic persuasion, d the only book of consequence which the former had his library was an English translation of the Bible, in hich young Geddes was instructed with such care and tention that he was able to give an account of the hisry of it before he had reached the eleventh year of his ge. The first instructions he received, after those of his rents, were communicated by a school-mistress in the inity, by whom he was so much distinguished that it came the first mental gratification which, in his own opion, he ever felt. He was next placed under the tuition of a young man from the city of Aberdeen, who had been engaged by a proprietor for the education of his own children; and afterwards went to a place called Scalan, in the ghlands, where those were to be trained up who desned to devote themselves to the Catholic priesthood, ad to finish their education at some foreign university. Here it was, in this obscure retreat, that Geddes laid the fundation of that intimate acquaintance with the learne languages by which he was so eminently distinguishe in the subsequent part of his life. He went to the Sotch university at Paris in the year 1758, and soon aerwards began the study of rhetoric in the college of Navarre. By the strength of his genius, and his indefatigable attention, he soon reached the head of this class, although he had to contend with two veterans; and became the favourite of Vicaire, the professor, whose friendship lasted till the close of his life.

Instead of entering into the philosophical class at the usual time, Geddes studied that subject at home, in order to facilitate his theological studies, on which he entered under MM. Buré and de Sauvent, at the college of Navarre; whilst Lavocat at the Sorbonne was his Hebrew preceptor. His progress in the oriental languages was so great that Professor Lavocat urged him strongly to continue at Paris; but his friends prevailed with him to return to his native country in 1764. His first charge as a priest was in a Catholic chapel in the county of Angus, from which he removed to Traquair in 1765, and became chaplain to the earl of that name, where he remained for about three years. This situation was most agreeable to his literary pursuits, as he had unlimited access to an extensive library, which greatly assisted him in the prosecution of his favourite studies. He left the earl's house in the year 1768, and returned to Paris, where he devoted his time during the following winter to the perusal of books and manuscripts in the king's libraries, making large extracts from scarce copies, particularly such as were in the Hebrew tongue.

In the spring of 1769 he returned to his native country, and became pastor of a congregation at Auchinhalrig, in Banffshire, where he was for some time involved in pecuniary difficulties, out of which he was extricated by the liberality of the Duke of Norfolk. These were occasioned by the debts he incurred in building a new chapel for his flock, and in making the parsonage house one of the neatest and most convenient in Scotland. With the view of bettering his circumstances he commenced farmer; but as he had to borrow money to stock his farm, and as the crops failed for three successive seasons, he was under the necessity of abandoning this scheme in a much poorer condition than when he first projected it. His unwearied exertions, however, joined to the assistance of friends, again relieved him, and he was enabled to discharge in an honourable manner every claim against him of a pecuniary nature.

In the year 1779 he resigned his pastoral charge at Auchinhalrig, which was a heavy blow to the members of his congregation, as the zeal and diligence with which he discharged the duties of his ministerial function had endeared him to all. He was also justly esteemed for his attention to the instruction of youth. Next year the university of Aberdeen conferred on him the degree of doctor of laws, a literary honour which had never been bestowed by that body on any Roman Catholic since the Reformation. He afterwards went to London that he might prosecute his favourite studies with greater facility, and give the world his English translation of the Old and New Testament, to which he had turned his attention for a number of years. He officiated for some months after his arrival at the imperial ambassador's chapel in Duke Street, until the term of Easter 1782, when it was suppressed by order of the Emperor Joseph II., after which Dr Geddes seems to have declined entirely the exercise of his clerical functions.

No sooner had the design of Dr Geddes, relative to a new translation of the Bible, been made public, than he met with formidable opposition from his Catholic brethren; an event which the doctor seems with good reason to have anticipated. His own words on this occasion were, "I expect not excessive profits from excessive exertion. I trust I shall never want meat, and clothes, and fire; to a philosophical and contented mind, what more is necessary?" He was many years employed in preparing this

Geddes.

important work for the press before he had any prospect of adequate success. In addressing the English Catholics on the subject of his translation, he says, "At any rate, I do what I think it my duty to do, and do it fairly and openly. In the following pages ye will find neither palliation nor disguise. I pour out my sentiments with the same sincerity as if I were before the tribunal of Him who is to judge the living and the dead. Mistake I may, but prevaricate I never will." He discovered this noble spirit in every action of his life, and in all his transactions and intercourse with mankind, although he did not conciliate the regard of those who could have bestowed upon him the most effectual assistance.

After spending much of his life in biblical studies, he met with a long and cruel interruption. "I had but little hope of ever living in a situation to resume them," says he, "when Providence threw me into the arms of such a patron as Origen himself might have been proud to boast of; a patron who, for these ten years past, has, with a dignity peculiar to himself, afforded me every convenience that my heart could desire towards the carrying on and completing of my arduous work." It is needless to inform the public, that the patron to whom the learned doctor here alludes was Lord Petre. For this munificence, continued throughout the whole of his life, and even beyond it by his will, Christians of every denomination will feel sentiments of gratitude, if they are qualified to form a true estimate of the advantages of free and impartial inquiry. His prospectus of a new translation of the Bible in 4to was published in 1786, and a letter to the Bishop of London on the same subject appeared in 1787. His proposals were printed in 1788.

In the year 1792 the first volume of this translation was published, dedicated to his patron Lord Petre, containing the first six books of the Old Testament. Soon after this volume made its appearance, three apostolic vicars, calling themselves the Bishops of Rama, Acanthos, and Centuriæ, issued a pastoral letter, addressed to their respective flocks over which they presided, warning them against the reception of Dr Geddes' translation. In his reply to the Bishop of Centuriæ we find these words: "Perhaps, my lord, you wish to have another occasion of exercising your episcopal authority, and of playing with censures as children do with a new ball. I wish your lordship much joy of the bauble; but however, my lord, beware of playing too often with it. Read St Chrysostom on ecclesiastical censures, and learn from him a little more moderation. Permit an old priest to tell you that it is a very great ornament in a young bishop. As to myself, my lord, I am not afraid of your threats, and shall laugh at your censures as long as I am conscious that I deserve them not. You cannot hinder me from praying at home; and at home I will pray, in defiance of your censure, as often as I please. The Chief Bishop of our souls is always accessible; and through him I can, at all times, have free access to the Father, who will not reject me, but for voluntary unrepented crimes. In the panoply of conscious innocence, the whole thunder of the Vatican would in vain be levelled at my head."

The second volume of his translation, owing to a variety of interruptions, did not make its appearance till the year 1797, to which was prefixed a dedication to her royal highness the Duchess of Gloucester, as an early, spontaneous, and liberal encourager of the work. In this volume the doctor gives up, and boldly combats, the absolute inspiration of Scripture, believing that the Hebrew, like all other historians, wrote from such human documents as they could find, and were of consequence liable to similar mistakes. This latitude of thinking naturally led the doctor to give up as fabulous, and wholly unworthy of the divine benevolence, every command, precept, and injunction, which appeared unworthy even of human authority. He denied, of consequence, that the command given to destroy the Canaanites could have had God for its author.

Gefleborg.

Dr Geddes was a man of extensive literature, uncommon liberality of thinking, and the friend of all mankind; a man of integrity, honour, and benevolence; in the strictest sense of the word a genuine Catholic, one whose love of truth was so invincible, that neither hopes nor fears could induce him to conceal it.

As a controversial writer, Dr Geddes was eminently distinguished by his letter to Dr Priestley, in defence of the divinity of Jesus Christ; and by one to a member of parliament, on the expediency of a general repeal of the penal statutes which have a respect to religious opinions. In the spring of the year 1800 he published an Apology for the Roman Catholics of Great Britain, in which he zealously defended his peculiar tenets; but displayed a commendable moderation when he mentioned the injuries to which he himself and brethren were subjected by the continuance of persecuting laws; and when he argued in behalf of abolishing all legal disabilities, he discovered the soundest logical understanding.

The principal works of Dr Geddes are, 1. Select Satires of Horace, London, 1779, 4to; 2. Prospectus of a new Translation of the Bible, ibid. 1786, 4to; 3. Letter to the Bishop of London, containing doubts, queries, &c., relative to a vernacular translation of the Holy Scriptures, ibid. 1787, 4to; 4. Letter to Dr Priestley, in which the author attempts to prove by one prescriptive argument that the divinity of Jesus Christ was a primitive tenet of Christianity, ibid. 1787, 8vo; 5. Epistola Macaronica ad fratrem de iis quæ gesta sunt in nupero Dissentientium conventu, 1790, 4to; 6. Carmen Sæculare pro Gallica gente tyrannidi aristocraticæ erepta, 1790, 4to; 7. Encyclical Letter of the Bishops of Rama, Acanthos, and Centuriæ (Walmsley, Gibson, and Douglas), with a continued commentary for the use of the vulgar, 1791; 8. The first book of the Iliad of Homer verbally rendered into English verse, 1792, 8vo; 9. L'Avocat du Diable, 1792, 4to; 10. Carmina Sæcularia tria, pro tribus celeberrimis libertatis Gallicæ epochis, 1793, 4to; 11. The Battle of Bangor, or the Church's Triumph, an heroi-comic poem, 1797, 8vo; 12. Translation of the Bible, vol. i. 1792, vol. ii. 1797; 13. A Modest Apology for the Roman Catholics of Great Britain, addressed to all moderate Protestants, 1800, 8vo; 14. Bardomachia, poema Macaronico-Latinum, 1800, 4to; 15. Paci feliciter reduci Ode Sapphica, 1801, 4to; not to mention a variety of fugitive pieces, and contributions to periodical publications. He had corrected and prepared his translation for the press up to the hundred and eighteenth psalm, when he was seized with an excruciating distemper, which put a period to his life on the 26th of February 1802.

GEFLEBORG, one of the provinces of Northern Sweden, extending from latitude 60. 10. to 62. 25. north, and from longitude 17. 15. to 21. 43. east, being 8008 square miles in extent. It comprehends four cities and 1807 insulated establishments, with 79,100 inhabitants. It is generally a hilly country, but abounding in extensive lakes. Not more than one fiftieth part of the land is cultivated, and much of that yields but scanty crops of rye or oats; but in bad years, food is so scarce that the rind of the fir-trees is used as a substitute for other aliment. The chief produce is iron, millstones, whetstones, and wood for fuel and building. Spinning and weaving for the families are conducted in each house, and their home-made woollen goods are both warm and durable.

GEFLEBORG, a city, the capital of the province of the same name, in Sweden. It stands on the river Geflean, which collects the waters of several lakes, and conveys them to the Gulf of Bothnia. It contains 1200 houses, and 5930 inhabitants. It is a town of considerable trade for the ex-

Gelli.

ort of iron, wood, pitch, and tar, and has some manufacures of sail-cloth, coarse linen, and leather, and some sugar efineries, distilleries, and breweries. Long. 17. 3. 10. E. at. 60. 39. 45. N.

GEFREES, a bailiwick of the circle of the Upper Maine, the kingdom of Bavaria, extending over 101 square iles. It contains two cities, two market-towns, and fiftyree villages, with 20,980 inhabitants. It produces some orn, but better hemp and flax, and much timber from the rests, which are very extensive. Some little gold and lver is found in the mountains. The capital is the town Berneck, containing about 1000 inhabitants.

GEHENNA, a Scripture term which has given some ouble to the critics. The authors of the Louvain and Geeva versions retain the word *gehenna* as it stands in the reek, and so does M. Simon ; the English translators renr it by " hell" and " hell-fire," and so do the translators Mons and Father Bohours. The word is formed from the ebrew *gehinnom*, or valley of Hinnom. In that valley, ich was near Jerusalem, there was a place named *Toet*, where some Jews sacrificed their children to Moloch, making them pass through the fire. King Josias, to nder this place for ever abominable, made it a cloaca or mmon sewer, into which all the filth and carcasses in the y were thrown. The Jews further observed, that there s a continual fire kept there to burn and consume those rcasses ; for which reason, as they had no proper term in eir language to signify " hell," they made use of *gehenna* *gehinnom* to denote a fire unextinguishable.

GEHREN, a market-town of the duchy of Schwartzburg-nderhausen, in Germany. It stands at the junction of rivers Wohlrose and Schobser, and contains 208 houses 1411 inhabitants. It is the capital of a bailiwick comhending two other towns, thirteen villages, and three mlets, with 9391 inhabitants.

GEISLINGEN, a bailiwick of the kingdom of Wurtemg, in the circle of the Danube. It extends over 134 sare miles, and comprehends three cities, three towns, ad sixty villages, with 22,680 inhabitants. The capital, o the same name, on the Rohrbache, contains 400 houses ad 2240 inhabitants, who are famed for their wood, horn, ad ivory turnery ware, and part of whom are employed in c ton spinning by means of machinery, and also in making t machinery.

GELDERS, a town of the Prussian province of Cleeve-Jiers, on the river Nierse, which runs into the Rhine. It ctains 394 houses, and 3470 inhabitants, who are employe in cloth and linen weaving, and in the tanneries.

GELDERS, or *Guelders*, a province of the Netherlands, cposed out of the ancient province of the same name, w the addition of the districts of Sevenaer, Huissen, and Msburg, ceded by Prussia. It extends over 2094 square mes, and contains 249,177 inhabitants. On the sea shore th land is flat ; and, by being well drained and embanked, it fertile in pasture. In the island formed by the Leck, th Rhine, and the Waal, it is sandy and rather hilly ; and on he south of the Maas it is boggy and marshy. It is csidered as the most healthy of the provinces of the Nethlands. The chief products of the soil are butter, cheese, wat, buckwheat, flax, rape-seed, and oil, tobacco, hops, wuts, and fruit. There is considerable manufacturing instry exercised in making diaper and damask tableclhs and other linen, in tanneries, in paper-making, in cuery, and in other iron goods. The division is into four cies, viz. that of Arnhem, of Zutphen, of Nemwegen, an Thiel.

ELLERT, Christian Furghtegott, was born on th 4th of July 1715, at Haynichen, near Freyberg, where his ather was a clergyman. He was extraordinary professo of philosophy at Leipsic, and a distinguished writer amg the Germans. When only thirteen years of age he showed himself possessed of poetical genius ; but having none to guide his taste for composition, he was led to imitate Gunther, Neukerch, and Hanke, men of indifferent abilities. He studied theology at Leipsic in 1734, and returned home at the expiration of four years, when he commenced public speaker ; but his timid disposition prevented him from shining as an orator in the pulpit. The delicacy of his constitution forbidding him to aspire after extensive learning, he confined himself to the acquisition of that which might render him useful. He was much respected for his first attempts in poetry, called *Amusements of Reason and Wit*, which appeared in 1742.

The labour which he found requisite for the composition of sermons inclined him to lay aside the clerical profession, and devote himself wholly to the instruction of youth, in which he not only implanted knowledge in the minds of his pupils, but also inspired them with the love of religion and virtue. He was made master of arts in 1744, and published the first volume of his Fables in the ensuing year. His *Swedish Countess* was the first German romance deserving of notice. He gave the world the second part of his Fables in 1748, although two years before this period he had been much afflicted with an hypochondriacal affection. In 1751 he was solicited to accept the office of extraordinary professor of philosophy, together with a decent salary, which was augmented on the termination of the war.

Assailed by unconquerable lowness of spirits and confirmed melancholy, he still exhibited the same patience, resignation, and universal philanthropy, as he had ever shown, qualities which excited the admiration of the enemy during the war. His sufferings continued to increase in severity, and at last terminated his existence on the 13th of December 1769. He contributed much to the improvement of the taste and morals of his countrymen, and their gratitude for his services made them deeply lament his loss. His praise was resounded by every voice, and his likeness was cast in gypsum and moulded in wax ; it was engraved on copper, and represented in sculpture and in painting.

It is said of this amiable man and captivating writer, by Kutner, who wrote the lives of German authors, that it will probably be a century before the appearance of another poet, so fully qualified to excite the love and admiration of his contemporaries, and to obtain so powerful an influence over the taste and habits of thinking of all descriptions of men. It would indicate too much partiality to call him a genius of the first class, but he certainly was a most agreeable and fertile writer ; a poet to whom religion and virtue are deeply indebted ; an able reformer of public manners, and fonder of affording consolation than of plunging into despondency. " As long," says Kutner, " as the Germans shall understand their present language, will the works of Gellert be read ; and his character will be honoured while virtue is known and respected." The following is a list of his principal works : 1. Dissertation on the Epistolary Style ; 2. Canticles, or Religious Poetry ; 3. Moral and Didactic Poetry ; 4. Tales and Fables ; 5. Comedies, Leipsic, 1745, in 8vo ; 6. The Swedish Countess of C * * * Leipsic, 1746, in 8vo ; 7. Mixed Works ; 8. Dissertations on Literature and Morals, Leipsic, 1747, in 8vo ; 9. Moral Lessons, published after his death by J. A. Schlegel and G. L. Heyer, Leipsic, 1770, in 2 vols. 8vo.

GELLI, John Baptist, an eminent Italian writer, was born of mean parents, at Florence, in the year 1498. He was bred a tailor, some say a shoemaker ; but he had such an extraordinary genius, that he acquired several languages, and made uncommon progress in the belles-lettres ; and, though he continued to work at his trade, became acquainted with all the wits and learned men at Florence, and his merit was universally known. He was chosen a member of the academy there, and the city made him a burgess.

He acquired the highest reputation by his works, which are, 1. Capriccj del Bottajo, Florence, 1548, in 8vo; 2. La Circe, Florence, 1549, in 8vo; 3. Two comedies in prose, one entitled La Sporta, and the other Lo Errore; 4. Tutti i Trionfi, Carri, Mascherate o Canti carnascialeschi, or songs composed for the popular festivities of Florence, from the time of Lorenzo the Magnificent till 1559; 5. Various translations from the Latin, as the *Hecuba* of Euripides, from the Latin of Erasmus, the Life of Alphonso of Este, Duke of Ferrara, from the Latin of Paulus Jovius, &c. Gelli died in 1563.

GELLIBRAND, HENRY, a laborious astronomer of the seventeenth century, was born in the year 1597. Though he was not without prospects of advancement in the church, yet he became so enamoured of mathematical studies, that on the death of his father he became a student at Oxford, contented himself with his private patrimony, and devoted himself solely to this study. On the death of Mr Gunter, he was recommended by Mr Briggs to the trustees of Gresham College, for the astronomical professorship there; and to this he was elected in the year 1627. As Mr Briggs died in 1630, before he had finished his *Trigonometria Britannica*, the work was, at his request, completed by Gellibrand. He wrote several other things, chiefly tending to the improvement of navigation; and died in 1636.

GELLIUS, AULUS, a celebrated Roman, who flourished under Antoninus Pius, A. D. 140, and died about the beginning of the reign of Marcus Aurelius. Of his private history we can only collect a few facts. He was the disciple of Fronto and Sulpicius Apollinaris; and as it was still the custom in his time for the young nobility to complete their education at Athens, it appears that Gellius proceeded to that city, and studied philosophy under Taurus and Peregrinus Proteus. On his return to Rome he attended the philosopher Favorinus, many of whose maxims he has transmitted to us. He is known to us particularly for a work entitled *Noctes Atticæ*, in twenty books, which he composed principally whilst residing on a small property belonging to him near Athens. It is still complete, with the exception of the eighth book. It consists of a number of extracts, which the author had made in the perusal of Greek and Latin authors, formed into a collection without our being able to perceive any particular connection or methodic arrangement. It is, however, of great value, as it furnishes us with many curious facts respecting the language, history, and antiquities of the ancients, as well as with numerous fragments of earlier writers now entirely lost, by which we are enabled to clear up many obscure points in ancient history. His style has been too highly commended by some, and decried by others. It is frequently careless, and there is a fondness displayed for obsolete expressions, those particularly used by the older comic writers, which gives it an air of affectation. Editions: Editio princeps ex recens. Jo. Andreæ, Rom. 1469, 1472; ed. cum not. et emend. Gronov. Lugd. Bat. 1687; Biponti, 1784; ed. A. Lion. Götting. 1824. (See Steinbrenner; Erzalungen nach Aulus Gellius, Zerbst. 1829.)

GELNHAUSEN, a town, or rather city, of Hesse Cassel, in the province of Hanau. It is on the great road from Frankfort to Saxony, which causes much active trade. The situation is fine, overlooking the river Kinsig; and the position being strong, was occupied by the Bavarian army to impede the French in their retreat after the defeat they had sustained at Leipsic in 1813. The Bavarians were however defeated, and Bonaparte secured the passage for his troops. It contains many inns, and 3140 inhabitants.

GELON, one of the most illustrious characters which Sicily produced, the chief transactions of whose life extend from the period when he became Prince of Gelon, 491, to his death, 478 B. C. He was descended from a family who had come from Telos, an island of the Egean Sea, into Sicily, when the city of Gela was founded. Here Gelon was born; and when Hippocrates fell in battle, the inhabitants of Gela made an attempt to free themselves from the dominion of his children. Gelon, however, espoused their cause; but when he had defeated their army, the opportunity to make himself tyrant of his native place was too favourable to be allowed to escape. His authority being established at Gela, he was invited by some exiles from Syracuse to use his influence to restore them to their country. In this too he was successful, and thus became sovereign of Syracuse, which he made the capital of his kingdom, 488 B. C.

It was now the policy of Gelon to embellish and improve the city of which he had made himself master. To increase its population, he compelled the inhabitants of Camarina, of Megara, and a portion of those of Gela, to take up their residence in his new abode; but he soon had affairs of a more important nature to occupy his attention. The power of the Carthaginians had already begun to make itself felt beyond their own immediate vicinity; and Gelon was not slow in perceiving that he must prepare for a formidable contest. He made application to the Greeks for assistance, 484 B. C.; but they refused to interfere; and by his own resources he succeeded in defeating the Carthaginians. It was now his turn to prove to the Greeks the folly of the policy which they had pursued. He refused to aid them, 480 B. C., when they were threatened with invasion by Xerxes, unless they consented to declare him commander-in-chief of the Grecian forces. To such a proposition they would not deign to listen, and in the mean time Gelon found sufficient employment in opposing the attacks of the Carthaginians. The two armies met near the city of Himera; and by a stratagem of Gelon, the Carthaginians were completely defeated, and their general Hamilcar killed.

From this period Gelon seems to have devoted himself to promote the happiness of his people. He increased the wealth of his kingdom, and employed himself in framing a code of laws on just and sound principles. On his deathbed he named his brother Hiero as his successor; and the high respect with which he was regarded by the Syracusans induced them to acquiesce in the appointment. (Herodotus, vii. 153, 166; Diodorus Sic. xi. 21-25. See HIERO.)

GEM, a common appellation for all precious stones, and particularly for those which are employed in jewellery. Brilliancy of lustre, richness of hue, and the most perfect transparency, are the desiderata of this class of minerals; and the value of those specimens in which such characters are combined is enhanced according to their size, in an extremely rapid ratio. At the head of the gems stands the diamond, which, for brilliancy of lustre, or *water* as it is termed, has not a rival. As elsewhere stated, it is principally the production of certain parts of Hindustan and Brazil, where it occurs in alluvial soil, or in conglomerate of the most recent formation. The oriental ruby, when perfect in transparency and colour, and of considerable size, vies with the diamond in value. Its most noted locality is the Capellan Mountains, near Syrian, in the kingdom of Ava. Next in order is the sapphire, which varies from a rich dark blue to a very slight tinge of the same colour, sometimes presents distinct colours in the same specimen, and is frequently transparent and colourless. It is met with in considerably larger masses than the preceding, and is only found in Ceylon. The peculiar colour of the emerald is well known. No gem is more frequently made mention of in sacred history, and none even at the present day stands in higher estimation amongst the crowned heads of the East. The aquamarine of lapidaries is, mineralogically speaking, a pale-blue variety of the same species, though one of very inferior value. Topazes occur under an infinity of forms, and are found in most quarters of the globe. From the changes which they undergo when exposed to heat, besides the fine colours they present naturally, topazes are peculiarly dapted to the purposes of the lapidary. The richest cooured garnets are the production of Ceylon and Greenand. Chrysolites of a brilliant pale-green colour are rought to Great Britain from Constantinople; hyacinths f a deep red from Ceylon; and tourmalines of a great ariety of hues from all parts of the world. The opal, nd many varieties of quartz, as the amethyst, onyx, arde, cats-eye, and agate, are also occasionally included nder the general denomination of gem.

Generally speaking, the different species of precious stones occur in small masses. All of them are found in a rystalline state, and present the peculiar forms which ature has assigned them. Many of these forms are sinularly beautiful; and their variety, particularly in the iamond and topaz species, is as great as any other class f the mineral kingdom affords. It is not, however, under these splendid forms that the gems are most commonly found. Most of them are the productions of Inia, Ceylon, Pegu, or Brazil, where, having been washed om their matrix in some of the primitive ranges, they are collected, in a rolled and rubbed state, in the channels of he rivers. Every trace of their original form is thus frequently lost; and, to add to the distress of the crystallographer, fine stones rarely come through the hands of Inan lapidaries without receiving farther abrasion or cutng. This circumstance of their so rarely presenting stinctive forms renders the peculiar hardness of this ass of stones a most important characteristic, and one which, whatever be their external shape or appearance, an never be mistaken. By this means too the real stone easily distinguished from the fictitious, which is occaonally made to bear so close a similitude, that an unractised eye finds it almost impossible to detect the difrence.

GEMAPPE, or JEMMAPPES, a village of the Nethernds, in the province of Hainault, near the river Scheldt, the road from Valenciennes to Mons. It is remarkable r the victory gained by the French under Dumouriez er the Austrians in 1792, by which the former became asters of the Austrian Netherlands.

GEMBLOUX, a town of the province of Namur, in the rcle of that name. It is situated on the river Orneau, d contains 1660 inhabitants, who are employed mostly the iron manufacture. It is remarkable for the battle ught near it in 1578, when the Austrians were defeated the Spanish army under the command of Don Juan of ustria.

GEMINI, in *Astronomy*, the TWINS, a constellation or n of the zodiac, the third in order, representing Castor d Pollux. These names are also given to two stars in ts constellation. Castor is a star of the third, and Polx of the second magnitude. The former, seen through a tescope, is a beautiful double star, that is, two stars of the fh and sixth magnitudes, one of which revolves about te other, forming a binary system.

GEMINIANI, a celebrated musician and composer, was bn at Lucca in the year 1680. He received his first insuctions in music from Alessandro Scarlatti; and after tt became a pupil of Carlo Ambrosio Lunati, surnamed *I Gobbo*, a most celebrated performer on the violin; after wich he became a disciple of Corelli, and under him fished his studies on that instrument. In the year 1714 h came to England, where in a short time he so recommnded himself by his exquisite performance, that all who pfessed to love and understand music were captivated with hearing him. Many of the nobility laid claim to the honour of being his patrons; but he seemed chiefly to attach himself to Baron Kilmansegge, chamberlain to King George I. as elector of Hanover, and a favourite of that prince. In 1716 he published and dedicated to his patron twelve sonatas *a violino, violone, e cembalo;* the first six with fugues, or double stops as they are vulgarly called; the last with airs of various measures, such as allemandes, courantes, and jiggs. This publication was so well relished by the baron, that he mentioned Geminiani to the king as an excellent performer; in consequence of which our musician had the honour to perform before his majesty, in concert with the celebrated Handel, who played on the harpsichord. But though Geminiani was exceedingly admired, yet he had not a talent for associating music with poetry, nor do we find that he ever became a public performer; he was therefore obliged to depend for his subsistence on the friendship of his patrons and the profits which accrued to him from teaching. He had also the misfortune to be an enthusiast in painting; and the versatility of his temper was such, that, in order to gratify this passion, he not only suspended his studies, and neglected to exercise his talents, but involved himself in debts. In 1727 he was offered the place of master and composer of the state music in Ireland; but this could not be conferred on a Catholic, and Geminiani refused to change his religion; upon which it was given to Matthew Dubourg, a young man who had been one of his pupils, and was a celebrated performer on the violin. Geminiani then set himself to compose parts to the *opera quinta* of Corelli; or, in other words, to make concertos of the first six of his solos. This work he completed, and, with the help of a subscription, at the head of which were the names of the royal family, published in 1726. In 1732 he published his *opera seconda*, which contains a celebrated minuet that goes by his name. He published many other pieces, the profits of which did not much mend his circumstances; but this perhaps was owing to his rambling disposition and enthusiastic fondness for painting. He was also an utter stranger to the business of an orchestra, and had no idea of the labour and pains necessary in the instruction of singers for the performance of music to which they were strangers. The consequence of this was, that a *concerto spirituale*, which he had advertised for his own benefit in 1748, failed in the performance. The audience, however, compassionated his distress, and sat very silent till the books were changed; when the performance was continued with compositions of the author's own, which he executed in such a manner as has never been forgotten. The profits arising from this performance enabled him to take a journey to Paris, where he staid long enough to get plates engraven for a score of solos, and the parts of two operas of concertos. About the year 1755 he returned to England, and advertised them for sale. In 1761 Geminiani went over to Ireland, and was kindly entertained there by Mr Matthew Dubourg, who had been his pupil, and was then master of the king's band in Ireland. This person, through the course of his life, had ever been disposed to render him friendly offices; and it was but a short time after Geminiani's arrival at Dublin that he was called upon to do him the last. It appears that Geminiani had spent many years in compiling an elaborate treatise on music, which he intended for publication; but soon after his arrival at Dublin, by the treachery of a female servant, who, it was said, had been recommended to him for no other end than that she might steal it, it was conveyed away, and could not be recovered. The greatness of this loss, and his inability to repair it, made a deep impression on his mind, and, as it is conjectured, hastened his end; at least he survived it but a short time, ending his days on the 17th of September 1762. The following list comprehends the whole of his publications, except two or three articles of small account, viz. twelve solos for a violin, *opera prima ;* six concertos in seven parts, *opera seconda ;* six concertos in seven parts, *opera terza ;* twelve solos for a violin, *opera quarta ;* six solos for a violoncello, *opera quinta ;* the same made into solos for a violin ; six concertos from his *opera quarta ;* six concertos in eight parts, *opera settima ;* rules for playing in taste ; a treatise on good taste ; the art of playing the violin ; twelve sonatas from his first solos, *opera undecima ;* Ripieno parts to ditto ; lessons for the harpsichord ; *Guido Armonica ;* supplement to this ; the art of accompaniment, two books ; his first two operas of concertos in score ; and the Enchanted Forest. Of his solos the *opera prima* is esteemed the best. Of his concertos some are excellent, others of them scarcely pass the bounds of mediocrity. The sixth of the third opera not only surpasses all the rest, but, in the opinion of the best judges of harmony, is the finest instrumental composition extant.

GEMISHKHANA, or SILVER-HOUSE, a town of Asia Minor, on the borders of Armenia, so called from a silver mine in its neighbourhood, which, however, has greatly declined in its produce. The town is better built than most towns in the Turkish dominions, and is said to contain 7000 inhabitants. It is thirty miles south from Trebisond.

GEMONIÆ SCALÆ, or *Gradus* GEMONII, amongst the Romans, was much the same as gallows or gibbet in England. Some say they were thus denominated from the person who raised them ; others, from the first criminals who suffered on them ; and others, from the verb *gemo,* I sigh or groan. The *gradus gemonii,* according to Publius Victor or Sextus Rufus, was a place raised on several steps, whence criminals were precipitated ; others represent it as a place whereon offenders were executed, and afterwards exposed to public view. The *gemoniæ scalæ* were in the tenth region of the city, near the temple of Juno. Camillus first appropriated the place to this use in the year of Rome 358.

GENAPPE, a town of the Netherlands, in the province of South Brabant, between Brussels and Namur. Being near to Waterloo, it became the scene of some bloody conflicts on the evening after the great battle of the 18th of June 1815. It contains 1400 inhabitants.

GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes. This was the original intention of gender ; but afterwards words, which had no proper relation either to the one sex or the other, had genders assigned them, and this was at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor* in Latin is feminine, but *arbre* in French is masculine ; and *dens* in Latin is masculine, but *dent* in French is feminine. The oriental languages frequently neglect the use of genders, and the Persian language has none at all. The Greeks and Latins generally content themselves with expressing the genders by different terminations ; as *bonus equus,* a good horse ; *bona equa,* a good mare. But in English we frequently go farther, and express the difference of sex by different words, as boar, sow ; boy, girl ; buck, doe ; bull, cow ; cock, hen ; dog, bitch, and so of others. We have only about twenty-four feminines distinguished from the males by the variation of the termination of the male into *ess ;* of which number are abbot, abbess ; count, countess ; actor, actress ; heir, heiress ; prince, princess, which is all that our language knows of any thing like genders. The Greek and Latin, besides the masculine and feminine, have the neuter, common, and doubtful gender ; and likewise the epicene, or promiscuous, which under one single gender and termination includes both the kinds.

GENEALOGY, an enumeration of a series of ancestors, or a summary account of the relations and alliances of a person or family, both in the direct and collateral line. The word is Greek, γενεαλογια, which is formed of γενος, *race* or *lineage,* and λογος, *discourse.*

GENEALOGICA ARBOR, or *TREE of Consanguinity,* signifies a genealogy or lineage drawn out under the figure of a tree, with its root, trunk or stem, and branches. The genealogical degrees are usually represented in circles, ranged over, under, and beside each other. This the Greeks called *stemmata,* a word signifying crown, garland, or the like.

GENERAL, an appellation given to whatever belongs to a whole genus.

GENERAL, in the art of war, he who commands a brigade, a division, a corps, or an army. See ARMY.

GENERAL is also used for the chief of an order of monks, or of all the houses and congregations established under the same rule. Thus we say the general of the Franciscans, Cistertians, and so on.

GENERALISSIMO, called also *captain-general,* and simply *general,* is an officer who commands all the military powers of a nation ; who gives orders to all the other general officers, and receives no orders himself excepting from the king. M. Balzac observes, that the Cardinal de Richelieu first coined this word, of his own absolute authority, upon his going to command the French army in Italy.

GENERATE, in *Music,* is used to signify the operation of that mechanical power in nature, which every sound has in producing one or more different sounds. Thus any given sound, however simple, produces along with itself its octave, and two other sounds extremely sharp, namely, its twelfth above, that is to say, the octave of its fifth, and the other the seventeenth above, or, in other words, the double octave of its third major. Whether we suppose this procreation of sounds to result from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear those proportions, one to another, as being determined at once by the partial and total oscillations of any musical string, or from whatever economy of nature we choose to trace it, the power of one sound thus to produce another, when in action, is said to *generate.* The same word is applied by Signior Tartini and his followers, to any two sounds which, when simultaneously heard, produce a third.

GENERATED, or GENITED, is used by some mathematical writers for whatever is produced, either in arithmetic, by the multiplication, division, or extraction of roots ; or in geometry, by the finding of the contents, areas, and sides ; or of extreme and mean proportionals, without arithmetical addition and subtraction.

GENERATING LINE, or FIGURE, in *Geometry,* is that which, by its motion of revolution, produces any other figure, plane, or solid.

GENERATION, in *Physiology.* See PHYSIOLOGY.

GENERATION is used, though somewhat improperly, for genealogy, or the series of children issuing from the same stock. Thus the gospel of St Matthew commences with the book of the generation of Jesus Christ. The latter and more accurate translators, instead of *generation* use the word *genealogy.*

GENERATION is also used to signify a people, race, or nation, especially in the literal translations of the Scripture, where the word generally occurs wherever the Latin has *generatio,* and the Greek γενεσις.

GENERATION is also used in the sense of an age, or the ordinary period of man's life. Thus we say, to the third and fourth generation. In this sense historians usually reckon a generation the space of thirty-three years or thereabouts.

GENERATOR, in *Music*, signifies the principal sound r sounds by which others are produced. Thus the lowest for the treble of the harpsichord, besides its octave, ill strike an attentive ear with its twelfth above, or G in lt, and with its seventeenth above, or E in alt. The C, herefore, is called their *generator*, the G and E its products or harmonics. But in the approximation of chords r G, its octave below is substituted, which constitutes a fth from the generator, or lowest C; and for E, is likeise substituted its fifteenth below, which, with the aboveentioned C, forms a third major. To the lowest notes, herefore, exchanged for those in alt by substitution, the enominations of products or harmonics are likewise given, hilst the C retains the name of their *generator*. But still, ccording to the system of Tartini, two notes in concord, hich when sounded produce a third, may be termed the ncurring generators of that third. (See *Génération armonique*, by M. Rameau; also the delineation of artini's system, called The Power and Principles of Harony.)

GENESIS, the first book of the Old Testament, conining the history of the creation, and of the lives of the st patriarchs. The book of Genesis stands at the head the Pentateuch. Its author is held to be Moses, and contains the relation of 2369 years, or from the beginng of the world till the death of Joseph. The Jews were rbidden to read the beginning of Genesis, and the benning of Ezekiel, until they had attained thirty years of ge. The Hebrews call this book *Beraschith*, because it gins with that word, which, in their language, signifies *principio*, or in the beginning. The Greeks give it the ame *Genesis*, Γενεσις, production, generation, because it gins with the history of the production or generation of l beings. This book, besides the history of the creation, ntains an account of the original innocence and fall of an; the propagation of mankind; the rise of religion; e general defection and corruption of the world; the luge; the restoration of the world; the division and opling of the earth; and the history of the first patrichs till the death of Joseph. It was easy for Moses to satisfied of the truth of what he delivered in this book, cause it came down to him through a few hands; for om Adam to Noah there was one man, Methuselah, who ed long enough to see them both; in like manner Shem nversed with Noah and Abraham, Isaac with Abraham d Joseph, from whom the records of this book might sily be conveyed to Moses by Amram, who was conmporary with Joseph.

Genesis, in *Geometry*, denotes the formation of a line, ane, or solid by the motion or flowing of a point, line, surface.

GENETHLIA, in *Antiquity*, a solemnity observed in emory of some person deceased.

GENETHLIACI, in *Astrology*, persons who erect hoscopes, or pretend to foretell what shall befall a man by eans of the stars which presided at his nativity. The rd is formed from the Greek *γενεθλη*, *origin*, *generation*, *tivity*. The ancients called them *Chaldæi*, and also by e general name of *mathematici*; accordingly, the various il and canon laws, which we find made against the maematicians, only respect the *genethliaci* or astrologers. ey were expelled from Rome by a formal decree of the nate, and yet found so much protection from the creduy of the people that they remained unmolested in the ty. Hence an ancient author speaks of them as *homim genus quod in civitate nostra semper et vetabitur et reebitur.*

GENEVA, a canton of Switzerland, comprehending the ty of that name, and the territory around it to the exnt of about ninety-eight square miles, with about 44,000 habitants, four fifths of whom reside within the city. Geneva, the largest city of Switzerland, is situated on the Lake of Geneva, where the river Rhone issues from it, and is divided by that river into two parts of unequal size. The streets are narrow, the houses lofty, and the appearance, except on the boulevards, is gloomy. It contains five reformed, one Lutheran, and one Catholic church, and about 30,000 inhabitants. It is a place of great activity in many branches of manufacture. The chief of these in amount is watchmaking and jewellery, in which many workmen are employed. Tanning, calico-printing, twine-spinning, hatmaking, whitesmiths' work, copper utensils, saddlery, silk and woollen shawls, besides copperplate and letterpress printing, are all occupations carried on, and the amount of which exported to other countries is very considerable. The fisheries in the Lake of Geneva and on the Rhone are also important branches of industry. Many individuals are said to have amassed very large fortunes, which they employ extensively in speculations in the funds of all nations, in banking, and in exchanges.

Much learning still exists in the city, and in former times it produced men of eminence in most branches of literature and science, among whom may be mentioned Calvin, Diodati, Tronchen, Casaubon, Rousseau, Neckar, Bonnet, and others. Long. 6. 4. 49. E. Lat. 46. 12. 15. N. See Switzerland.

Geneva *Lake*. This lake is in the shape of a crescent. Switzerland forms the hollow, and Savoy the convex part, the greatest breadth being about twelve miles. The country on the side of Savoy is full of high and craggy mountains; but from Geneva to the environs of Lausanne it slopes to the margin of the lake, and is very rich and fertile. The banks rise considerably in the neighbourhood of Lausanne, and form a most beautiful terrace, with a rapid descent a few miles beyond the town. In the neighbourhood of Vevay a plain begins, and continues for a great way beyond the end of the lake, but is contracted towards the water by the approach of the mountains. The lake itself appears at a distance of a beautiful blue colour, and the water is very clear and transparent. Near Geneva the coast of the lake abounds with pebbles; between that city and Lausanne it is sandy; from thence to Chillon it is bounded by hard calcareous rocks; and the extremity of the shores is a marsh formed by mud collected from the river Rhone. The greatest depth of this lake found by M. de Luc is a hundred and sixty fathoms.

Geneva, or *Gin*, among distillers, an ordinary malt spirit, distilled a second time, with the addition of some juniper berries.

GENEVIEVE, Fathers or Religious of, the name of a congregation of regular canons of the order of St Augustin, established in France. The congregation takes its name from the abbey of St Geneviève, which is the chief of the order, and whose abbot is the general thereof. The abbey itself took its name from St Geneviève, the patroness of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the church of St Geneviève, under the name and invocation of St Peter, where her relics are still, or were till lately preserved, her shrine visited, and her image carried in procession with great ceremony upon extraordinary occasions.

GENEVOIS, a province of Savoy, with the title of dukedom, in the kingdom of Sardinia, and on the borders of Switzerland. It extends over 682 square miles, contains three cities, and 147 towns and villages, with 69,867 inhabitants. By the congress of Vienna this province, as well as those of Chablais Faussigny, and the upper part of Chambery, wherein Rumelly is situated, are declared to be for ever neutral territories. The capital of the province is Annecy.

GENIAL, an epithet given by the Pagans to certain gods who were supposed to preside over generation. The genial gods, says Festus, were Earth, Air, Fire, and Water. The twelve signs, together with the sun and moon, were also sometimes ranked in the number.

GENII, a sort of intermediate beings, believed by the Mahommedans to exist, between men and angels. They are of a grosser fabric than the latter, but much more active and powerful than the former. Some of them are good, others bad, and they are capable of future salvation or damnation like men. The orientals pretend that these genii inhabited the world many thousand years before the creation of Adam, under the reigns of several princes, who all bore the common name of Solomon; that falling at length into an almost general corruption, Eblis was sent to drive them into a remote part of the earth, there to be confined; and that some of that generation still remaining were by Tahmurath, one of the ancient kings of Persia, forced to retreat into the famous mountain of Kaph. They also established several ranks and degrees among this kind of beings, some being called absolutely *Jin*, others *Peri* or fairies; some *Div* or giants, others *Tacwin* or fates.

GENITES, among the Hebrews, those descended from Abraham, who were without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were descended from parents who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in *Grammar*, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the *genitive case;* but in the modern languages a sign is made use of to express the relation of this case. In English the particle *of*, in French *de* or *du*, is prefixed. But in strictness there are no cases in either of these languages, inasmuch as they do not express the different relations of things by different terminations, but by prepositions, which is otherwise in the Latin.

GENIUS, a good or evil spirit or demon, whom the ancients supposed to watch over every person, to direct his birth, accompany him in life, and be his guard till death. Amongst the Romans the name *genius* was, according to Festus, given to the god who had the power of doing all things, *deum qui vim obtineret rerum omnium gerendarum;* but Vossius (*De Idol.*) prefers reading *genendarum*, and Censorinus frequently uses *gerere* for *gignere*. Accordingly St Augustin (*De Civitate Dei*) relates, after Varro, that the genius was a god who had the power of generating all things, and presided over them when produced. Festus adds that Aufustius spake of the genius as the son of god, and the father of men, who gave them life. Others, however, represented the genius as the peculiar or tutelary god of each place; and it is certain that the last is the most usual meaning of the word. The ancients had their *genii* of nations, of cities, of provinces, and the like. Nothing is more common than the inscription on medals of *Genius Populi Rom.*, the genius of the Roman people; or *Genio Pop. Rom.*, to the genius of the Roman people. In this sense *genius* and *lar* were the same thing; as, in effect, Censorinus and Apulius affirm they were.

GENIUS, in literature and the fine arts, a natural talent or disposition to do one thing more than another, or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently and with a great deal of pains.

GENLIS, an arrondissement of the department of the Oise, in France, extending over 530 square miles. It is divided into seven cantons, and these into 151 communes, inhabited by 73,912 persons. The capital, of the same name, is a city situated on the river Nonnette. It is an ill-built place. The cathedral has the loftiest tower of any in France. It contains nine other churches, two hospitals, with 940 dwellings, and 4520 inhabitants. It has manufactories of linen, lace, leather, cutlery, and some cotton spinning. Long. 2. 29. 53. E. Lat. 49. 12. 8. N.

GENOA, a duchy forming a part of the kingdom of Sardinia, in Italy, which, till the congress of Vienna, was the ancient republic of that name. On the north it is bounded by Piedmont, Parma, and Tuscany, on the east by Massa-Corrara, on the south by the Mediterranean Sea, and on the west by Nice. It extends over 2420 square miles. It was before transferred to the king of Sardinia, and divided into provinces; but when the Ligurian republic was established by the French, it was by them formed into four departments. These lines of demarcation have, however, been abolished, and now the duchy is formed into fifteen circles or arrondissements, the boundaries and extent of which are not accurately defined, but each of which has its separate intendancy. The population is 609,500, living in nineteen cities and 725 towns and villages.

The duchy is a narrow strip of land bordering on the Mediterranean, and enclosed by the Apennines, which separate it from the rest of Italy. It may be viewed in two parts: 1*st*, The mountains, which are mostly bare and barren, except in some valleys between them, and are impassable, except by two roads which lead to Piedmont and eastern Italy; 2*dly*, the sea-coast, where the land rises slip by slip in the form of terraces, and is for the most part sandy on the lower elevation; whilst on the higher, what little soil there is is mixed with slate.

The greater part of the land belongs to the old Genoese noble families, or to the clergy; and the cultivator either farms it at a rent in produce, or on joint account with the proprietor. The whole duchy scarcely grows as much wheat, maize, and barley, as serves for three months' consumption, and the deficiency is supplied either from Piedmont or from more remote countries. The chief product of the soil is the olive, the oil of which forms the most valuable article of export; but besides that, large quantities of oranges, citrons, pomegranates, and pine-apples, are sent to France, to Switzerland, and to Germany. Figs, almonds, capers, truffles, and morels, are exported to more distant markets. Chestnuts are grown abundantly on the mountains, and, with potatoes, form among the poorer classes substitutes for bread. The wine in general is of a bad quality, with few and insignificant exceptions. The cultivation of silk is moderate in quantity and inferior in quality. The fishery is pursued with little success, as the fish is scarce, except those of the smaller kinds.

The manufactures sank during the revolutionary scenes which the republic of Genoa witnessed; but they have been gradually returning to their former prosperity of late years. They now make silks and silk hosiery, fine thin woollens, hats, shoes, paper, chocolate, white lead, silver goods, and much candied fruit, which form articles of export. The restoration of the Bank of St George, which has now a capital of 1,220,000 livres, has been found highly beneficial to commerce. The other sea-ports, besides Genoa, are Spezzia, Savona, Porto Maurizzio, Vintigmilia, Finale, and Sestri. The population at present amounts to about 80,000.

GENOA, a city, the capital of the duchy of that name, is the seat of an archbishop, of the government boards, and of the senate. It is in the form of an amphitheatre, the streets rising above one another from the sea-shore, so that it has a magnificent appearance at a distance. It is surrounded with fortifications, which are very extensive, as they enclose both gardens and fields. The interior of the enclosure or city consists of irregular and narrow streets, in which magnificent palaces and houses six stories high are crowded together. The Strada Novi and

Genovesi.

the Strada Balbi, which consist of palaces, are not more than twenty-four feet wide, and the Piazza Reale is the only part which is tolerably open and airy. The city contains, besides the cathedral, fifty-two parish churches, and sixty-nine others belonging to different convents. There are several hospitals, two of which receive 1000 patients each, and several other charitable institutions. There is a university, with a library of 70,000 volumes and 1000 manuscript works, besides other establishments for in- truction in the fine arts and the sciences.

The most remarkable object is the harbour, enclosed by two moles, each 7000 feet in length, at the termination of which stand the light-houses. It is capable of receiving hips of the greatest draught of water, which are secure gainst all winds but that directly south. More than 3000 essels, besides coasters, enter it yearly. The inhabitants re industrious, and provide many articles for commerce, which are noticed in the account of the duchy in this work. The theatres and other conveniences are numer- us, and splendidly conducted, as in other Italian cities. Long. 8. 53. 2. E. Lat. 44. 23. 48. N.

GENOVESI, Anthony, an eminent Italian writer, was orn on the 1st of November 1712, at Castiglione, near alerno, in the kingdom of Naples. From his earliest ears he showed an uncommon capacity; but after receiving such education as his native village could afford, his ather obliged him to devote himself to the study of scho- astic theology, with a view to the ecclesiastical profes- on. In a short time he distinguished himself as a pro- cient in dialectics; but having formed an attachment to young woman, he was on the point of sacrificing to her l his professional prospects, when his father, who had btained a knowledge of the circumstance, removed him o another village, where he found a priest who diverted is attention to different objects. Having been afterwards xcommunicated by the Archbishop of Conza, for acting part in a comedy, he returned to Castiglione, where, aving found his mistress married, he re-assumed the cas- ock, and took priest's orders at Salerno in 1736. Here e soon distinguished himself so much by his talents and nowledge, that the archbishop of this town confided to im the chair of eloquence. At this period Genovesi was mere school theologian; but a friend of his, a young ec- esiastic, now made him aware that there were sources f knowledge beyond the scholastic sphere, more exten- ve, more interesting, and more real, than those to which e had hitherto applied. Genovesi entered into this new ntellectual world by the perusal of some romances; from hese he proceeded to the study of history; and, stepping om one subject to another, he finally applied himself to he study of modern philosophy, and read with attention he works of Leibnitz and Locke. In the hope of acquiring ill further information, he repaired to the capital; and s he did not possess the necessary means of maintaining imself there, he resolved to exercise the profession of ad- ocate; but having become disgusted with the details of ractice, he soon sacrificed his hopes of fortune to the leasures of study. He improved his knowledge of the reek, and of several of the modern languages, attended l the most celebrated professors of the university of aples, and soon perceived the imperfections of the exist- g system of public instruction.

Notwithstanding the progress which philosophy had ade in other countries, the kingdom of Naples was, at hat period, in a state almost retrograde, or at least sta- onary. Genovesi felt this, and he resolved to accom- ish certain reforms in the system of education, with a ew to the amelioration of the condition of his country- en. None ever succeeded better in this generous de- gn. Although there existed at Naples a university ce- brated for the learning of several of its professors, the pupils had long been accustomed to carry on their studies in private schools. Genovesi having conceived the design of opening one of these seminaries, he procured the appointment of extraordinary professor of metaphysics in the university, in order that he might appear before the public in a known character. He had formed peculiar methods of his own in all the faculties which constitute the philosophical course; and his first essays induced him to publish his *Elements of Metaphysics*, of which the first volume appeared in 1743, and afterwards, in 1745, his *System of Logic*.

In these two works he made ample use of the doctrines of Bacon, Descartes, Leibnitz, and Locke; and having substituted philosophical doubt for implicit belief, the observation of nature for the speculations of the schools, and reason for authority, this was sufficient to cause him to be denounced as an infidel, or at least as an irreligious person, by those who still adhered to the scholastic methods. He would probably have fallen a sacrifice to these prejudices, had he not been supported by Galiani, archbishop of Tarentum, grand almoner of the king, and grand master of the university; but notwithstanding this protection, he experienced some trouble and difficulty in obtaining the professorship of moral philosophy; and he was disappointed in an attempt to procure the chair of theology.

The unjust and obstinate hostility which he suffered on account of his theological works diverted him, for some time, from this dangerous path of inquiry, and brought him back to that of philosophy. He published a continuation of his *Elements of Metaphysics*, but, with every new volume, he continued to experience the censures and opposition of the partisans of the scholastic routine. Amongst these were the Cardinal Spinelli, archbishop of Naples, and an Abbé Magli, whom Genovesi covered with ridicule, in his work entitled *Lettere a un Amico Provinciale*. In spite of these continual jarrings, Genovesi obtained the approbation and esteem of Pope Benedict XIV., of several cardinals, and of most of the learned men who at that period flourished in Italy. Of this number was Intieri, a Florentine, who having spent a long time at Naples, became much attached to that country. This man, as distinguished for his philanthropical qualities as for the extent and solidity of his acquirements, was still more estimable on account of the use which he made of his fortune. It is to him that Italy is indebted for her first chair of political economy; he founded it, at his own expense, with the sanction of government, in the university of Naples, under three conditions, namely, that the lectures should be given in Italian, that Genovesi should be the first professor, and that, after his death, no ecclesiastic should succeed him.

Genovesi opened his first course of lectures on the 5th of November 1754, with great success. The novelty and the interest of the subject, the eloquent style and agreeable manner of the professor, attracted a crowd of auditors, and made a deep and lively impression. Nothing, indeed, was talked of but agriculture and commerce. To gratify the taste of the public for these new inquiries, he afterwards published his *Lectures on Commerce*, and Carey's *Account of the Trade of England*, translated into Italian by his brother, and enriched with notes by himself. His *Lectures on Commerce* was indisputably the most interesting work he had hitherto published. There are some errors, indeed, in his method, and even in his doctrines; but the work contains many important truths relative to every department of public administration, and a good application of analysis to subjects which had not hitherto been sufficiently investigated. Finally, it had the merit of being the first work which introduced into Italy, and particularly into the kingdom of Naples, a taste for the study of political economy.

The great success of these lectures, which were delivered in Italian, induced Genovesi to draw up a complete code of philosophy in that language. It was at this time the custom in Italy, and particularly at Naples, to teach every thing in Latin; a practice which prevented knowledge from spreading among those classes to whom that language was not familiar; and the Neapolitans, at that period, wanted education perhaps more than any other people. He had published, in Italian, his *Meditazioni Filosofiche,* on religion and morals; and his *Lettere Accademiche,* on the utility of the arts and sciences; a treatise written in opposition to the well-known work of Rousseau on that subject. Following out his plan, he began to recast all his Latin works, to improve their form, and to give them a more interesting character. The first which he published was his treatise on *Logic;* a work which went through several editions. He afterwards published his *Metaphysics,* divided into three parts; the first containing an essay on cosmology, the second on theology, and the third on anthropology. In 1767, he published part of a work on the *Science of the Rights and Duties of Man;* but this work was never completed. In all his writings, and particularly in his *Meditations* and *Letters,* the style is somewhat affected; at the same time they present us with a good exposition of the ideas and systems of the most celebrated philosophers.

After the suppression of the order of the Jesuits, when it became a question with the government whether they ought to be reinstated in their superintendence of public instruction, Genovesi was consulted, and his advice was, to replace the scholastic chairs by schools of mathematics, physics, and history; and he proposed one chair for the illustration of Cicero's *Offices.*

From the commencement of the year 1763, Genovesi had felt the symptoms of a dangerous malady; but he continued to teach and to write to the last day of his life; and before his death he had the satisfaction of witnessing the great success of his labours. Since the days of Telesius and Campanella, no school had attained more credit and celebrity at Naples than that of Genovesi. Pupils, some of them men of the most illustrious rank, flocked to his lectures; and those who heard him generally adopted his ideas and followed his maxims. He handled the most abstruse subjects in the most agreeable manner, and in a style almost poetical; a circumstance which gave him a great command over the attention, as well as over the judgment, of his pupils. Indeed all that Italy has since produced in philosophical and economical science may be said to have originated in the school which he founded. He died of an attack of dropsy, on the 22d of September 1769, aged about fifty-seven.

The following list of Genovesi's works is taken from Fabroni, *Vitæ Italorum doctrina excellentium:* 1. Disciplinarum metaphysicarum Elementa Mathematicum in morem adornata, 1744–1751, 4 vols. 8vo; 2. Elementorum Artis logico-criticæ libri quinque, Naples, 1745; 3. Discorso sopra alcuni trattati d'Agricoltura, ibid. 1753; 4. Lettere Accademiche, ibid. 1764; 5. Storia del Commercio della Gran Brettagna, &c. 1757; 6. Delle Lezioni di Commercio; 7. Discorso sopra l'Agricoltura, with a translation of Tull's Husbandry; 8. Discorso sul volgarizzamento del Saggio Francese sull' Economia de' grain, Naples, 1765; 9. Meditazioni Filosofiche sulla Religione e sulla Morale, ibid. 1766; 10. Della Filosofia del giusto e dell' onesto, 1766–1776, 3 vols.; 11. Universæ Christianæ Theologiæ elementa dogmatica, historica, critica, a posthumous work, Venice, 1771, 2 vols. 4to.

GENTIAH, a small district of Hindustan, situated on the north-east of Bengal, bounded on the south by Sylhet, and on the north by the Garrow Mountains. The inhabitants are Hindus of the Brahminical persuasion, and are governed by their own rajah, who is tributary to the Anglo-Indian government.

GENTIAH, the capital of the above district, lies without the pale of the Company's territories, being situated in long. 91. 54. E. and lat. 25. 10. N.

GENTILE, in matters of religion, a pagan, or worshipper of false gods. The origin of this word is deduced from the Jews, who called all those who were not of their name כויים *gojïm,* or *gentes,* which in the Greek translations of the Old Testament is rendered τα εθνα; and in this sense it frequently occurs in the New Testament. The Latin church also used *gentes* in the same sense as *gentiles,* especially in the New Testament. But the word *gentes* soon obtained another signification, and no longer meant all such as were not Jews, but those only who, being neither Jews nor Christians, followed the superstitions of the Greeks and Romans. In this sense it continued amongst the Christian writers, till their manner of speech, together with their religion, was publicly and by authority received in the empire; and then, in treatises and laws concerning religion, gentiles signified pagans, in opposition to Jews and Christians; and in civil affairs the word was used to signify all such as were not Romans.

GENTILE, in Roman law and history, a name which sometimes expresses what the Romans otherwise called *barbarians,* whether they were allies of Rome or not; but this word was used in a more particular sense to indicate all strangers and foreigners who were not subject to the Roman empire.

GENTILESCHI, HORATIO, an Italian painter, was born at Pisa in 1563. After having made himself famous at Florence, Rome, Genoa, and other parts of Italy, he removed to Savoy; whence he proceeded to France, and at last, upon the invitation of Charles I., came over to England. He was well received by that king, who appointed him lodgings in his court, together with a considerable salary, and employed him in his palace at Greenwich, and other public places. The most remarkable of his performances in England, were the ceilings of Greenwich, and York House. He also executed a Madona, a Magdalen, and Lot with his two daughters, for King Charles; all which he performed admirably well. He made several attempts in face painting, but with little success; his talent lying altogether in histories, with figures as big as the life. After twelve years continuance in England, he died at eighty-four years of age, and was buried in the Queen's Chapel, at Somerset House.

GENTILIS, ALBERICUS, a laborious jurisconsult of the sixteenth century, with more erudition than taste or judgment, was born in 1551 at Castello-di-San-Genesio, in the march of Ancona, and studied at Perugia, where he took the degree of doctor in civil law at the age of twenty-one. Soon afterwards he obtained the situation of judge in the city of Ascoli; but not having it in his power to profess there in security the Protestant religion, of which he was an ardent follower, he went to seek an asylum in Carniola, and ultimately in England. During his stay at London, where he continued for several years, he lived entirely on the bounty of some generous friends of the sciences. At length the Earl of Leicester, his protector, procured him, in 1587, the chair of law in the university of Oxford, of which he was chancellor. This place, with the appointment which Gentilis soon afterwards received of perpetual advocate of the subjects of the king of Spain, in all causes which they might have in England, enabled him to spend the remainder of his days in comfort. He died at the commencement of the year 1611. The labours of Albericus Gentilis in jurisprudence give him but small claims to our esteem. His views are often erroneous, and the sound doctrines which may be found in his works are buried in a mass of citations without end, from the philoophers, fathers, poets, historians, and jurisconsults. This normous erudition betrayed him into inconsistencies in natters of importance; and hence has Bayle reproached im with having indirectly sanctioned Catholic opinions n some controverted points, although he was otherwise a ealous Protestant. But his treatises on the law of na- ons have rendered his name worthy of a place in the his- ory of jurisprudence. His book *De Jure Belli* contains xcellent views on a science which Aristotle and Cicero ave not even touched on; and if the author has not suf- ciently fathomed his subject, and too frequently decided y the precepts of religion and morality questions which e purely political, he has at least the merit of having fur- shed abundant materials to Grotius, who knew better how use them. An exact list of his works may be found in e *Mémoires* of Niceron (tomes xv. and xx.); but it may sufficient here to indicate the following: 1. Liber Condi- onum, Wittemberg, 1580, 8vo; 2. De Juris Interpreti- s dialogi sex, London, 4to; 3. De injustitia bellica Ro- anorum actio, Oxford, 1590, 8vo; 4. De Jure Belli li- i tres, Hanau, 1598, 8vo; 5. Disputationes duæ, prima actoribus et spectatoribus fabularum non notandis, se- nda de abusu mendacii, Hanau, 1599, 8vo; 6. Ad Joan- em Rainoldum de Ludis Scenicis epistolæ duæ, Middel- rg, 1699, 4to; 7. Disputationes tres, prima de libris ris Canonici, secunda de libris Juris Civilis, tertia de atinitate veteris Bibliorum versionis male accusata, Ha- u, 1604 and 1605, 8vo; 8. De Linguarum mixtura dis- tatio parergica, Hanau, 1604, 8vo. (A.)

GENTILIS, *Scipio*, brother to the preceding, and also a vilian of some note, left his native country that he might enly profess the Protestant religion. He obtained the ofessorship of Roman law at Altorf, through the influence Hugues Doneau, in which situation he soon distinguished mself by his success as a teacher, combining considerable arning with a brilliant imagination, and a ready elocu- on. He died of a dysentery, on the 6th of August 1616, aving several works, amongst which may be mentioned, De Donationibus inter virum et uxorem libri iv. Frank- rt, 1604, in 4to; 2. De Erroribus Testamentorum a estatoribus ipsis commissis, et de dividuis et individuis ligationibus, Strasburg, 1699, in 8vo.

GENTLEMAN. Under this denomination are com- ehended all above the rank of yeomen, and hence noble- en are truly called *gentlemen*.

The word is formed of the French *gentilhomme*, or ra- er of *gentil*, fine, fashionable, becoming, and the Saxon *n, honestus*, or *honesto loco natus*. The same significa- on belongs to the Italian *gentilhuomo*, and the Spanish *hi- lgo*, or *hijo dalgo*, that is, the son of somebody, or a per- n of note. If we go farther back, we shall find *gentleman* iginally derived from the Latin *gentilis homo;* which was ed amongst the Romans to signify a race of noble persons the same name, born of free or ingenuous parents, and ose ancestors had never been slaves or put to death by v. Hence Cicero in his *Topics* says, *Gentiles sunt, qui ter se eodem sunt nomine, ab ingenuis oriundi, quorum jorum nemo servitutem servivit, qui capite non sunt dimi- ti.* Some hold that it was formed from *gentile*, meaning gan; and that the ancient Franks, who conquered Gaul, en converted to Christianity, were called *gentiles* by the tives, as being yet heathens. Others state, that in the cline of the Roman empire, as recorded by Ammianus arcellinus, there were two companies of brave soldiers, the e called *gentiles*, and the other *scutarii;* and that hence derive the names *gentleman* and *esquire*. (See ESQUIRE.) is opinion is confirmed by Pasquire, who supposes the pellation *gentiles* and *ecuyers* to have been transmitted us from the Roman soldiery; especially as it was to the *ntiles* and *scutarii*, the bravest of the soldiery, that the incipal benefices and portions of land were assigned.

GENTOOS. See HINDUSTAN.

GENUFLEXION (from *genu*, knee, and *flecto*, I bend), the act of bowing or bending the knee, or rather of kneeling down. The Jesuit Rosweyd, in his *Onomasticon*, shows that genufluxion, or kneeling, was a very ancient custom in the church, even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitsuntide, when kneeling was forbidden by the council of Nice. Others have shown, that the custom of not kneeling on Sunday had obtained from the time of the apostles, as appears from Irenæus and Tertullian; and the Ethiopian church, scrupulously attached to the ancient ceremonies, still retain that of not kneeling at divine service. The Russians esteem it an indecent posture to worship God upon the knees. Baronius is of opinion that genuflexion was not established in the year of Christ 58, founding on that passage in Acts (xx. 36) where St Paul is expressly mentioned as kneeling down at prayer; but Saurin shows that nothing can thence be concluded. The same author also remarks that the primitive Christians carried the practice of genuflexion so far, that some of them had worn cavities in the floor where they prayed; and St Jerome relates of St James, that he had contracted a hardness on his knees equal to that of camels.

GENUS, among metaphysicians and logicians, denotes a number of beings which agree in certain general properties common to them all, so that a genus is nothing else but an abstract idea, expressed by some general name or term.

GENUS, in *Rhetoric*. Authors distinguish the art of rhetoric, as also orations or discourses, into three *genera* or kinds, namely, demonstrative, deliberative, and judicial. To the demonstrative kind belong panegyrics, genethliacons, epithalamiums, and funeral harangues; to the deliberative, persuasions, dissuasions, and commendations; to the judicial, defences and accusations.

GENUS, in *Natural History*, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, which agree in certain common characters.

GENUS, in *Music*, by the ancients called *genus melodiæ*, is a certain manner of dividing and subdividing the principles of melody; that is, the consonant and dissonant intervals, into their concinnous parts. The moderns considering the octave as the most perfect of intervals, and that on which all the concords depend, in the present theory of music the division of that interval is considered as containing the true division of the whole scale. But the ancients went to work somewhat differently. The diatessaron, or fourth, was the least interval which they admitted as concord; and therefore they sought first how that might be most conveniently divided, and then constituted the diapente and diapason. The diatessaron being thus, as it were, the root and foundation of the scale, what they called the *genera*, or kinds, arose from its various divisions; and hence they defined the *genus modulandi* the manner of dividing the tetrachord, and disposing its four sounds as to succession. The genera of music were three; the enharmonic, the chromatic, and the diatonic. The first two were variously subdivided; and even with regard to the last, though it is commonly reckoned not to have any species, different authors have proposed different divisions, but without giving any particular names to the species, as was done in the two others.

GEOCENTRIC, in *Astronomy*, is applied to a planet, or its orbit, to denote that it is concentric with the earth, or has the earth as its centre or the same centre with the earth.

GEOFFROY OF MONMOUTH, Bishop of St Asaph, called by our ancient biographers *Gallofridus Monumentensis*. Leland conjectures that he was educated in a Benedictine convent at Monmouth, where he was born about the beginning of the twelfth century, and that he afterwards became a monk of that order. Bale, and after him Pits, call him archdeacon of Monmouth; and it is generally believed that he was created Bishop of St Asaph in the year 1151 or 1152, under the reign of King Stephen. Some time afterwards he repaired to the court of Henry II. who received him with distinction, and fixed him near his own person by the gift of a rich abbey. The canons of St Asaph having to no purpose urged Geoffroy to return to his diocese, profited by the decision of a synod held at London to make him a last offer either to resume the administration of that part of the church committed to his care, or to consent that a successor should be appointed in his charge. In 1175, Geoffroy divested himself of his bishopric; but he had soon reason to repent this step, since he lost the benefices which had been conferred upon him by Henry II. He is believed to have died about the year 1180. His history, which was probably completed after the year 1138, contains a fabulous account of British kings, from the Trojan Brutus to the reign of Cadwallader in the year 690. But Geoffroy, whatever may be thought of his credulity, was not the inventor of the stories which he relates. His history is a translation from a manuscript written in the British language, and brought to England from Armorica by his friend Gualterus, or Gauthier, archdeacon of Oxford. But the achievements of King Arthur, Merlin's prophecies, speeches, and letters, were chiefly his own addition. Geoffroy takes credit to himself for being the first who wrote the history of the times that preceded the establishment of Christianity in England; but as he admits that in every thing which concerns the kings of Saxon origin, he merely translated into Latin from the work which had been sent him by the archdeacon of Oxford, it does not appear that he has much cause to plume himself on this score, or that he can lay claim to the credit of originality, and at the same time escape the charge of invention. Wharton's excuse, that fabulous histories were then the fashion, and popular traditions a recommendation of a book, may be available to a romancer, but is ridiculous when alleged in behalf of an historian. In as far, however, as he merely translated, he is not to be held responsible for the legends which he published in a Latin version; and although his history as a whole is doubtless a tissue of counterfeit facts and fabulous anecdotes, yet there seems to be no sufficient ground for the reproaches which have been cast upon him by Twin and Wear, who have chosen to brand him as the father of lies. In an age of profound ignorance and boundless credulity, the wildest fictions were greedily swallowed, and the supernatural, the miraculous, or the impossible, easily amalgamated with the unquestioning faith of a superstition founded on the prostration of reason. Belief may be honest, though its object is falsehood. Besides, as Pits and Nicolson have observed, Geoffroy may be relied on, in the account he gives of events which either fell under his own observation, or in regard to which he had it in his power to procure accurate information. He was not an inventor of fables; and those which he retailed he derived from the source already indicated, namely, the Armorican manuscript brought to England by Gualterus. His works are, 1. Origo et gesta Regum et Principum Britanniæ, sive Historia Britonum ab Ænea et Bruto, Paris, Badius, 1517, in 4to, reprinted in the Britannicarum rerum Scriptores, Heidelberg, 1587, in folio; 2. Versio prophetiarum Ambrosii Merlini, Frankfort, 1603, in 4to; 3. Vita Merlini Caledonii; 4. Commentarius in prophetias Merlina utriusque; 5. Epistolæ ad Gualterum Oxoniensem archidiaconum; 6. De Exilio Ecclesiasticorum; 7. An abridgment of the History of Gildas; 8. Latin verses on different subjects. A treatise De corpore et sanguine Christi is also attributed to him; but Fabricius is of opinion that the author of this work is William, abbot of St Thierry at Reims.

GEOFFROY, Stephen Francis, a physician eminent for his chemical and botanical knowledge, was born at Paris on the 13th of February 1672, where his father kept an apothecary's shop, and had been several times in the magistracy. He received a liberal education; and, whilst prosecuting the study of medicine, he had conferences at his father's house with Cassini, Duverney, Homberg, and other men of distinguished eminence. At Montpellier he attended the lectures of the ablest professors of physic, and afterwards visited the south of France, carefully viewing every object deserving of his attention. He accompanied Count de Tallard to England in 1698, where he became acquainted with the leading men of science, and was admitted a member of the Royal Society. He next went into Holland, and in 1700 he accompanied the Abbé de Louvois in a tour to Italy. On his return, he became a licentiate in 1702, and, in two years after, he was created doctor of medicine. One of his theses was *A vermibus hominum ortus interitus?* which was translated into French under this title, *Si l'Homme a commencé par être vers?* for the sake of some ladies of high rank, by whom it was deemed interesting.

Geoffroy did not hastily commence the practice of medicine, continuing the prosecution of his studies in retirement for some years. He appeared nowise anxious to push himself forward, although his knowledge made him often be consulted by several gentlemen of the faculty; and he felt so concerned for the recovery of his patients, that it imparted to him an air of melancholy, which at first alarmed them, till they became acquainted with the cause. In 1709, he was appointed by the king professor of physic to the Royal College, vacant by the death of the celebrated Tournefort, and began with lectures on Materia Medica; but in 1712, Fagon resigned to him the chemical chair, and on both subjects Geoffroy lectured with unwearied assiduity. He was twice chosen as dean by the faculty of Paris, and from the year 1699 he filled a place in the Royal Academy of Sciences. Anxious to discharge his various functions with credit, his health at last sunk under fatigue, and he died upon the 5th of January 1731. He is known to the chemical world by his table of affinities, which is far superior to any that had appeared before his time. His greatest work was his *History of the Materia Medica*, which was published in an unfinished state, after his death, Paris, 1741, in 3 vols. 8vo. This learned and laborious author enriched the *Mémoires* of the Academy of Sciences with different articles, the principal of which were, 1. Table des Différents Rapports observés en Chimie entre différents Substances, and Eclaircissements sur cette Table, 1718 and 1720; 2. Observations sur le Vitriol et sur le Fer, 1713; 3. Sur les Dissolutions et sur les Fermentations que l'on peut appeler froides, parce qu'elles sont accompagnées du refroidissement des Liqueurs dans lesquelles elles se passent, 1700; 4. GEOGRAPHY.

INTRODUCTION.

The term Geography, derived from two Greek words, α, *the earth*, and γραφω, *I write*, signifies *a description of the earth.* The description to which this title is applied may be more or less general; either embracing such truths only as belong to the earth considered as one whole, or extending to particulars which belong to and distinguish the several countries spread over its surface. In whichsoever of these two aspects the subject be regarded, a vast field opens to the view of the observer. In order to give a full and accurate description of the earth, it would be requisite to consider it in reference to its motion, figure, and magnitude; in reference to its relation to the other bodies of the universe, and more especially to the planetary system of which it forms a part; in reference to its surface, as diversified by land and sea, mountains and valleys, lakes and rivers; in reference to the materials which compose its crust, and to its internal structure; in reference to the constitution of the atmosphere with which it is surrounded, and the effects arising from the variations in atmospherical pressure, temperature, and humidity. Nor would it be enough to consider the earth only as a mass of inert and unorganized matter; it would be necessary to regard it in its relations to vegetable and animal life; and to trace the phenomena which these, in their endless variety, present in its various divisions and provinces. It would still further be necessary to view it as the abode of man himself, and as modified by his existence; divided into states and kingdoms; adorned with cities, and all the noble monuments of civilized life.

Such is an outline of the picture which geography, in its most unlimited meaning of the term, should exhibit of the globe. To fill up this picture in all its parts, it would evidently be necessary to call in the aid of the whole circle of the sciences. But the description is usually of a less extended character, being confined chiefly to the more obvious and striking features of the various regions and countries of the earth.

In the wide range which the subject presents, several divisions and subdivisions are suggested by the different views in which the earth may be considered. The three following divisions are the most important:

1. *Mathematical Geography*, which illustrates, on astronomical principles, the figure, magnitude, and motion of the earth; teaches how to determine the positions of places on its surface; explains the construction of globes, with their application to the solution of problems; and shows how the whole or any portion of the earth's surface may, on the principles of projection, be delineated on a map or chart.

2. *Physical Geography*, which treats of the mutual relations of the diversified objects found on the surface of the earth, including the atmosphere by which it is surrounded; and explains the causes, whether of a chemical or mechanical description, that produce the modifications and changes which they continually undergo.

3. *Political* or *Historical Geography*, which describes the earth as divided into countries, occupied by various nations, and improved by human art and industry. It traces the circumstances and character of the different races and tribes of mankind, explaining their social institutions, and ascertaining the place which each occupies in the scale of civilization.

From this general arrangement of the subject, it is evident that geography depends for its rank as a science on its intimate connection with various branches of knowledge, which, taking their rise from investigations instituted in reference to the nature and mutual relations of the objects on the earth, or connected with it, furnish those accurate views which must be obtained before any thing like a precise description can be given of the globe we inhabit, or of any portion of it. With regard to what belongs to Physical Geography, we must refer the reader to the articles Physical Geography, Mineralogy, Meteorology, &c. in this work. What belongs to Political or Historical Geography will be found under the names of the respective countries. The following article will be limited to a view of the progress of Geographical Discovery, and to a brief explanation of the principles of Mathematical Geography.

I.—VIEW OF THE PROGRESS OF GEOGRAPHICAL DISCOVERY.

There are many circumstances in the condition of man which connect him so closely with the globe which he inhabits, as to render absolutely necessary to his existence a knowledge of at least the neighbourhood of the spot where his lot is cast. It is from the earth that he must derive the means of subsistence and accommodation, the materials on which his industry is to be exerted, and those objects in the exchange of which commerce consists. In every stage of his progress, therefore, from barbarism to civilization, he must employ some attention and observation, in order to discover in what respects the objects with which he is surrounded are qualified to contribute to the supply of his wants, and to his comfort and convenience. Even while he roams the forest in the savage state, he must make himself acquainted with many circumstances, a knowledge of which is necessary either to give him success in the chase, or to direct him in retracing his steps to the place where he has fixed his dwelling. But it is not until men have united in society, and that neighbouring communities have begun to hold mutual intercourse, that those feelings and passions are effectually aroused which stimulate to the arduous pursuits of geographical discovery. Commerce and war, with the spirit of adventure which usually accompany them, have without doubt been among the first causes of geographical research. In the train of these have followed the workings of avarice and the aims of ambition. As the human mind has advanced in its career of improvement, curiosity, with an enlargement of views and desires, have been called into action; and voyages have been undertaken for the express purpose of discovering new countries and exploring unknown seas.

In tracing the effects which these causes have produced in the gradual increase of geographical knowledge, it will contribute to distinctness to keep in view a threefold division, which the subject naturally assumes, namely, *ancient* geography, extending from the earliest period of history down to the time when, the Roman empire having been overrun by barbarous nations from several quarters, Europe was overwhelmed in the darkness which preceded the revival of learning; the geography *of the middle ages*, extending from the revival of letters to the fifteenth century, when the discoveries of the Portuguese began to lay a wider foundation for the science; and *modern* geography, which embraces the most recent discoveries, and is progressively improving by the accessions which it is receiving from the labours and science of modern travellers and navigators.

The Phœnicians are the earliest commercial people of whose discoveries we have any correct accounts. This people seem first to have explored the coasts of the Mediterranean. Their navigators at length extending their voyages through the Straits of Gades, now called the Straits of Gibraltar, entered the Atlantic Ocean, and visited the western coasts of Spain and Africa. In many places to which they resorted they planted colonies; and sought, by instructing the inhabitants, in some measure, in their arts and improvements, to open a wider sphere for their commerce. The learned Bochart, led by the analogy between the Phœnician tongue and the oriental languages, has endeavoured to follow the tracks of the Phœnicians, both along the shores of the Mediterranean and those of the Atlantic. These analogies are not always sure guides; but there seems no reason to doubt that Cadiz was originally a Phœnician colony, and it is not likely that this was the only one formed by that enterprising people.

The Arabian Gulf, or Red Sea, offered to the Phœnicians another field of naval and commercial exertion, to the improvement of which the distance of Tyre, the emporium of their trade, was the only obstacle. This induced them to make themselves masters of Rhinocrura or Rhinocolura, the port in the Mediterranean nearest to the Red Sea. Commodities purchased in Arabia, Ethiopia, and India were landed at Elah, the safest harbour in the Red Sea towards the north; thence they were conveyed over land to Rhinocolura; and being there reshipped, they were carried to Tyre, whence they were distributed over the world.

The wealth and power which accrued to the Phœnicians from their being in the sole possession of the lucrative trade of the East, incited the Jews, their neighbours, under the prosperous reigns of David and Solomon, to desire a participation in its advantages. Their conquest of Idumea, which stretches along the Red Sea, put it in the power of Solomon to fit out a fleet; while his alliance with Hiram, king of Tyre, enabled him to command the skill of the Phœnicians for the conducting of the voyage. Passing through the Straits of Babelmandel, they carried on commerce in the Indian Ocean; and so distant were the countries to which they traded, that the voyage occupied no less than three years. But though the Jews thus for a time engaged in the pursuits of trade, yet the tendency of their institutions, which were expressly designed to preserve them a separate people, was unfavourable to the development of the commercial spirit which their monarchs wished to foster among them. This, joined with the division of the kingdom on the death of Solomon, proved fatal to their rising greatness as a commercial people, and excluded them from ranking among the nations who have contributed to the advancement of geographical knowledge. It is perhaps impossible to fix with certainty the limits which bounded the geographical researches of the Phœnicians, on account of the difficulty there is of assigning the precise places marked out by the names then given to the countries to which they traded. The length of time occupied in the voyage, and the nature of the cargoes brought home, with a few other circumstances of the same vague kind, are the only particulars afforded to direct us in the determination. Thus the country of Ophir, to which the Phœnicians navigated the ships of Solomon, must be ascertained by the facts that the voyage thither and homeward occupied three years, and that the cargo consisted of "gold and silver, ivory, and apes, and peacocks." Among the various opinions which have been entertained respecting the position of this distant country, the most probable appears to be that it was situated on the eastern coast of Africa, as far south as Sofala. To this quarter every indication seems clearly to point; and whatever objections may appear to stand in the way, in consideration of the remoteness of the region, and the difficulties to be encountered, these admit of being answered by a reference to the length of time required for the voyage, and to the wealth, naval skill, and ample resources, at the command of the monarchs engaged in the traffic.[1]

The Carthaginians, a Phœnician colony, retained in full vigour the commercial spirit of the parent state. They did not, however, attempt to divide with Tyre the wealth and power which she derived from the monopoly of the trade carried on in the Arabian Gulf. They directed their efforts to the opposite quarter, and sailing through the Straits of Gades, pushed their researches far beyond the bounds which had been reached by the mother country in this part of the globe. They visited not only all the coast of Spain, but likewise that of Gaul, and penetrated at length as far as the south-western coast of Britain, where they obtained tin from the mines of Cornwall or in traffic with the natives. Nor was it only towards the northward that they directed their efforts; they explored also the regions southward of the straits, and sailing along the western coast of Africa almost as far as the northern tropic, they planted colonies, as the Phœnicians of Tyre had formerly done, with a view to prepare the natives for carrying on commercial intercourse. The Atlantic Ocean was destined to conceal for ages from the inhabitants of the old world the immense regions which lie beyond it. But the Carthaginians extended the boundary of navigation westward by the discovery of the Fortunate Islands, now known by the name of the Canaries.

The enlargement of views gradually generated by this spirit of commercial enterprise led at length to voyages of which discovery was the special object. The circumnavigation of Africa was one of the earliest attempts of this nd made by the ancients. The direction which the coast kes beyond the Mediterranean on the one hand, and the ed Sea on the other, suggested the idea of a peninsula hich it might be possible to sail round. This voyage was st undertaken by the Egyptians; a people exceedingly erse to engage in naval affairs, but who at this time were led over by Necho, a monarch whose active spirit prompt- him to engage some Phœnicians to descend the Arabian lf, and, coasting along Africa, to endeavour to return by Straits of Gades. Herodotus narrates in a few words result of this enterprise, which was undertaken about hundred and four years before the Christian era. He ys, "the Phœnicians, setting sail from the Red Sea, made ir way into the southern sea; and when autumn approached they drew their vessels to land, sowed a crop, d waited till it was grown; when they reaped it, and ain put to sea. Having spent two years in this manner, the third year they reached the pillars of Hercules, and urned to Egypt, reporting what does not find belief with , but may perhaps with some other person; for they d that in passing Africa they had the sun on their right nd. In this manner Lybia was first known."

---

[1] The regions always spoken of in Scripture as the most remote with which the Hebrews and Phœnicians were acquainted are, Tarshish, Ophir, the Isles, Sheba, and Dedan, the River, Gog, Magog, and the North. Without entering into any discussion, we may give what appear to be the most probable conclusions with regard to the positions of the countries to which these names were applied. Tarshish is a country from which two voyages are spoken of in Scripture as being made; one by the Mediterranean, bringing iron, silver, lead, and tin, the produce of Spain and Britain; the other by the Red Sea, bringing gold, ivory, and other productions of tropical Africa. These two voyages, though at first sight they appear incongruous if supposed to be made to the same country, may be reconciled by supposing that Tarshish is fundamentally Carthage, which monopolized almost entirely the commerce of Spain and Britain, and was the medium through which the commodities of the west were distributed; and that the name of this great African metropolis was extended to the whole of the continent of Africa. The Isles are the whole southern coasts of Europe, consisting either of real islands or peninsular tracts. Sheba is the southern portion of that part of the coast of Arabia which borders on the Red Sea; while Dedan lies upon the opposite coast, that borders on the Persian Gulf. These countries rose to commercial importance in consequence of the valuable commodities which were imported into the former from the African coast, and into the latter from India. Thence arose the traffic carried on by "the companies of Sheba," or caravans, and by "the travelling companies of Dedanim." The River was the name always applied to the Euphrates. Gog, Magog, and the North, appear to be the high tableland in the interior and north of Asia Minor, Phrygia, Galatia, Cappadocia, and Paphlagonia, regions in which may be recognised the peculiarly rude and formidable aspect which belonged to the countries to which in ancient times the names in question were applied. (See *Encyclopædia of Geography*, by H. Murray, Esq.)

This passage has given rise to much controversy among learned. But the voyage here so briefly described es not seem to involve any impossibility, notwithstanding then infant state of navigation; and the circumstance ich the historian objects to as incredible is the very point ich, from its coincidence with what we know should have pened, renders the story more worthy of belief.

Xerxes king of Persia, according to Herodotus, gave a ilar commission, about four hundred and eighty years ore the Christian era, to one of his satraps, named Sapes, who, for a heinous offence, had been condemned to . If successful in the accomplishment of this voyage, taspes was to escape a cruel death; but the difficulties re too great to be surmounted by a navigator brought amidst the luxury and indulgence of the Persian court. ving procured from Egypt a vessel and crew, he passed ough the Straits of Gades, entered the Atlantic Ocean, l, bending his course towards the south, coasted the conent of Africa, until, after several months, he probably ched the coast of Sahara. The frightful and desolate ores along which he sailed, and the tempestuous ocean ich beat against them, combined to fill his mind with rm, and to shake his resolution. He retraced his course the straits; and hoping perhaps that the labours he had lergone in the partial accomplishment of the task imed on him would be accepted by his royal master as a ficient atonement for his offence, or that the offence itself ght in a great measure be forgotten, he returned home presented himself before Xerxes. The cause which he igned for the failure of the ultimate object of his misn was, that he had encountered a sea so full of herbage t his passage was completely obstructed. This reason e grounds of which have never been satisfactorily exined, though it *has* been alleged that obstacles of this cription occur in that part of the sea which lies between Cape Verd Islands, the Canaries, and the coast of Afriappeared so ridiculous to Xerxes, that he ordered the tence of death by crucifixion, which had been pronoun- upon Sataspes, to be immediately executed.

But the most celebrated voyage of antiquity undertaken the purpose of discovery was the expedition under Han- fitted out by the authority of the senate of Carthage, and the public expense, and that with the view of attempting omplete survey of the western coast of Africa. Of all voyages performed by the Phœnicians and Carthagins, this is the only one of which we have an authentic rative. Mercantile jealousy prevented these two great nmercial states from communicating to other nations the owledge which they acquired of the remote regions of the earth; and from this cause, when the maritime power of the former was annihilated by Alexander's conquest of Tyre, and the empire of the latter was overthrown by the Roman arms, all monuments of their great skill in naval affairs appear in a great measure to have perished. Even the account of the voyage of Hanno (*Periplus Hannonis*) has been considered by its learned editor Mr Dodwell as a spurious work. But the arguments of M. de Montesquieu and of M. de Bougainville appear fully to establish its authenticity, which the learned world now generally admit.

Hanno set sail with a fleet of sixty vessels, so constructed that, according to the mode of ancient navigation, he could keep close in with the coast. We are told that, in twelve days after leaving the Straits of Gades, he reached the island of Cerne; that proceeding thence, and following the direction of the coast, he arrived, in seventeen days, at a bay, which he called *The West Horn.* From this he advanced to another bay, which he named *The South Horn.* The objects which are described as having been seen by Hanno in his progress belong to tropical Africa. But in attempting to ascertain the places which he visited, or the utmost distance which he sailed southward, much difficulty and uncertainty are experienced. Bougainville supposes Hanno to have reached the Gulf of Benin, and contends that this limit, distant as it is, cannot be regarded as beyond what may be conceived to have been accomplished by the most skilful navigator of antiquity. Major Rennell shortens the distance considerably by conceiving the voyage to have been extended no further southward than Sherbro Sound, a little beyond Sierra Leone. He thus obtains the advantage of avoiding a difficulty involved in the hypothesis of M. de Bougainville; namely, the supposition of ancient ships having sailed upwards of seventy geographical miles in a day. At the same time, the arguments which support the one hypothesis are equally applicable to the other.

According to the views of M. Gosselin, however, the voyage must be confined to much narrower limits southward than even those assigned by Major Rennell. He supposes it to have terminated about the river Nun; an opinion which he supports by alleging that, in such a voyage, the progress must necessarily have been slow. The Carthaginian navigator had to encounter all the obstacles and dangers incident to a course held along a shore, and in a sea, which were equally unknown. He must have found himself impeded by the requisite examination of every part of the coast, as well as by the many precautions which the safety of the fleet under his command must have rendered constantly necessary. With regard to the circumstances given in the narrative which appear to point to tropical Africa, M. Gosselin supposes that the same aspect of life and nature may, at that distant period, have belonged to Morocco, then thinly peopled by the rude native tribes, which is now specially characteristic of more southern regions.

Amidst such diversity of opinion among the learned, it is not easy to decide in reference to a subject beset with so many difficulties. If we assume either of the more remote distances assigned for the termination of the voyage, Cerne must be identified with the isle of Arguin; and, on Major Rennell's hypothesis, the Gulfs of Bissago and Sherbro present those numerous islands described by Hanno, to which there are no islands corresponding on any other part of the coast. On the whole, however, the most limited distance seems preferable, if we admit that part of M. Gosselin's hypothesis which assigns to Morocco features of man and of nature that are usually held to be characteristic of tropical Africa.

The circumnavigation of Africa was an enterprise which in ancient times not only called forth the naval efforts of the most powerful maritime states, but which also awakened the ambition of private adventurers. Eudoxus, a native of Cyzicus, being sent on a mission to Alexandria, at that time the seat of naval enterprise and geographical knowledge, his ardent mind, naturally biassed to these pursuits, was aroused to action by the spirit which prevailed in that city. He began his career under the auspices of Ptolemy Euergetes, the reigning Egyptian monarch, who fitted out a fleet, and placed it under his command. According to the destination assigned him, Eudoxus descended the Arabian Gulf, and proceeded probably as far as the southern shore of Arabia. Thence he appears to have returned, after a prosperous voyage, with a valuable cargo of aromatics and precious stones. But of this wealth he appears to have been deprived by Euergetes. After the death of this monarch, which in a short time took place, his widow Cleopatra sent Eudoxus on another voyage, in the course of which he was driven by unfavourable winds on the coast of Ethiopia, where he was kindly received by the inhabitants, and carried on with them an advantageous traffic. After other vicissitudes of fortune, he was induced by circumstances which occurred in his adventurous life to leave the court of Egypt, and repair to the commercial city of Cadiz, in Spain, and there to fit out an expedition for the purpose of African discovery. At Massilia (Marseilles), and other maritime places through which he passed on his way to Cadiz, he took care to make known his views and hopes of success, and to invite all who were actuated by any spirit of enterprise to accompany him. He succeeded in fitting out a ship and two large boats; on board of which he carried not only goods and provisions, but artisans, medical men, and even players on musical instruments. This was no doubt proceeding on a magnificent scale. But his crew was ill calculated to second his bold undertaking. To avoid the danger of stranding, Eudoxus was anxious to keep the open sea. His companions, however, alarmed at the swell, forced him to adopt the usual mode then followed of sailing along the shore; a measure which led to the disaster which he had anticipated. With one vessel of a lighter construction, on board of which was put the more valuable part of the cargo, Eudoxus pursued his voyage until he reached a part of the coast inhabited by a race of people that appeared to him to speak the same language with those whom he had found on the opposite side of the continent. Judging from this circumstance that he had ascertained the main object of his voyage, he returned and endeavoured to obtain the assistance of Bocchus, king of Mauritania. Suspecting, however, treachery on the part of that monarch, he again had recourse to Spain. Here he was again successful in equipping another expedition, consisting of one large vessel fitted for the open sea, and another of smaller size for the examination of the coast. This was a judicious preparation for the accomplishment of the object in view; but with regard to the issue of the voyage no accounts of any authority have been preserved.

Such are the leading circumstances connected with the voyages of Eudoxus, which are narrated by Strabo; and, notwithstanding the scepticism and severe criticisms of that geographer, there is really nothing to which the candid reader can reasonably refuse his belief. Prejudices, founded, for the most part, on his own want of information, led Strabo to treat likewise as fabulous the relation of the only ancient voyage having Europe, and more particularly the British isles, for its object, of which we have any detailed account.

Pytheas, a Massilian navigator, undertook an expedition about three hundred and twenty years before the Christian era. He steered northward; and after examining the coasts of Spain and Gaul, he sailed round the island of Albion; and, stretching still farther to the north, he discovered an island, the *Ultima Thule* of the ancients. What island this was the learned are not agreed. It has been supposed to be the modern Iceland; but this implies too great an extent of open sea for an ancient navigator to traverse; and besides, six days, the period during which he is said to have navigated to the northward of Albion before he made his discovery, are too short a time to admit of his reaching Iceland. Others, amongst whom is Malte-Brun, have considered Jutland as Ultima Thule. But it should be kept in view that Pytheas uniformly regarded Thule as British, a character which he could scarcely conceive to belong to Jutland, seeing he could have reached that peninsula only by a long course along the coasts of Germany, which must have impressed on his mind the idea that he had left far behind him every thing belonging to Britain. On the whole, Shetland seems best entitled to be considered as the ancient Thule, and suits well with the appellation which Pytheas gives it, when he expressly calls it the "furthest of the Britains."

Strabo endeavours to throw discredit on the statements of Pytheas, by starting objections long known to be of the most groundless description; and it is an advantage which the traveller and navigator possess who describe faithfully the grand features of nature, that, however prejudice may dim their reputation for a time, yet will their accuracy as well as veracity at length, in the progress of knowledge, appear, and secure for them the respect and applause of mankind. At the same time, it must be admitted that, in describing what he saw beyond his Ultima Thule, the statement given by Pytheas, as reported by Strabo, assumes a somewhat fabulous character. He asserted, it seems, that beyond Thule there commenced what was neither earth, sea, nor air, but a confused blending of all the three. But even here some allowance is to be made for the workings of imagination under very peculiar circumstances, and a readiness, not unnatural, to believe reports which represented him to have reached the extremity of the habitable globe. If his language is not too literally interpreted, it will be found to convey a strongly figurative, but not altogether imperfect, description of the state of the sea and sky in these climes, which have been so little favoured by nature.

The conquests of Alexander the Great, by making known the East, enlarged the bounds of geographical knowledge. Though the course of his expedition was for the most part by land, his mind was equally intent on commerce and maritime discovery. Checked as he had so long been in the career of his victories by the opposition and efforts of the republic of Tyre, he had an opportunity afforded him of observing the vast resources of a maritime power, and at the same time of forming a judgment respecting the immense wealth to be derived from commerce, especially from that carried on with India, which he found to be wholly in the hands of the Tyrians. With a view to secure this commerce, as soon as he had completed the conquest of Egypt, he founded the city of Alexandria, and thus established for it a station preferable in many respects to Tyre. After his final victory over the Persians, his march in pursuit of Bessus, who had carried off Darius into Bactriana, often led him near to India, and among people accustomed to much intercourse with it, from whom he learned many things concerning the state of the country, that served so to confirm and inflame a desire which he had long cherished of extending his dominion over those regions, that he was induced to conduct his army from Bactria, for the purpose of invasion, across that ridge of mountains which form the northern barrier of India. After passing the Indus, Alexander directed his march to the Ganges, which, from the accounts he heard of it, and of the countries through which it flows, he was eager to reach. The route which he found it necessary to follow, in consequence of being successively engaged in hostilities with various native princes, led him through one of the richest and best peopled countries in India, now called Punjab. In his ultimate object, however, he failed.

His march being performed during the rainy season, his troops had already suffered so much, that notwithstanding the high degree in which he possessed all those qualities that secure an ascendency over the minds of soldiers, he was unable to persuade them to advance beyond the banks of the Hyphasis, the modern Beyah, which was accordingly the utmost limit of Alexander's progress in India.

By this expedition, Alexander first opened the knowledge of India to the people of Europe; and as he was accompanied, wherever he went, by skilful surveyors, Diognetes and Baeton, who measured the length and determined the direction of every route taken by the army, he furnished a survey of an extensive district of it, more accurate than could have been expected from the short time he remained in that country. The memoirs drawn up by his officers likewise afforded to Europeans their first authentic information respecting the climate, the soil, the productions, and the inhabitants of India.

Though Alexander did not penetrate to the Ganges, his expedition prepared the way to the knowledge of that magnificent stream. For soon after, Seleucus, one of his successors, sent Megasthenes as his ambassador to Palibothra, the capital of a powerful nation on the banks of the Ganges. The site of Palibothra was probably the same as that of the modern city of Allahabad, at the junction of the river Jumna with the Ganges. This embassy brought new and opulent provinces of India into view, an acquaintance with which served to raise still higher the idea generally entertained of the value and importance of the country.

The island *Taprobane*, so celebrated among the ancients, which appears, notwithstanding some great mistakes with respect both to extent and position, to be the modern Ceylon, seems not to have been known in Europe even by name before the age of Alexander. In consequence, however, of the enlightened and active curiosity with which he explored every country which he subdued or visited, some knowledge of it was at length obtained; and, after his time, it is mentioned by almost every ancient geographer.

Whilst Alexander was attempting to penetrate into India, a numerous fleet was assembled by officers whom he had left on the banks of the Hydaspes, the modern Behat or Chelum, with orders to build and collect as many ships as they could. The destination of this fleet was to sail down the Indus to the ocean, and from its mouth to proceed to the Persian Gulf, with a view of opening a communication between India and the centre of his dominions. When Alexander reached the banks of the Hydaspes on his return, he committed the conduct of this expedition to Nearchus. The voyage down the Indus derived splendour from the greatness and magnificence of the armament, which consisted of an army of a hundred and twenty thousand men, and two hundred elephants, and of a fleet of nearly two thousand vessels. Alexander himself accompanied Nearchus in his navigation down the river, with one third of the troops on board; whilst the remainder, in two divisions, one on the right and the other on the left of the river, accompanied them in their progress. Having reached the ocean after the lapse of nine months, Alexander left Nearchus and his crew to pursue their voyage, and conducted his army back by land to Persia. A coasting voyage of seven months brought Nearchus, with the fleet, in safety, up the Persian Gulf into the Euphrates. It was at the mouth of the Indus that the Greeks witnessed for the first time, and that with astonishment and terror, the ebb and flow of the sea; a phenomenon scarcely perceptible in the Mediterranean, to which their navigation had formerly been confined. In the progress of the voyage they were also struck with surprise on observing phenomena belonging to the midsummer of the tropics. At noon objects were observed to project no shadows, or to project small shadows declining to the south. Their attention was still further attracted by the new appearance of the sky. Stars which they had been accustomed to see high in the heavens were now seen near the horizon. Some stars to the north disappeared, while other stars formerly invisible were seen in the south.

The opening of a communication between the Red Sea and the Persian Gulf was with Alexander another great object of ambition. But though with this view he seems to have sent expeditions down both seas, he failed in his attempts to accomplish this project.

Among the Romans, navigation and commerce, the handmaids of geographical science, were never made objects of pursuit, except in so far as they were found to be necessary to forward their schemes of universal dominion. Their conquests opened indeed the west, as those of Alexander had made known the east; and it might be truly said of that great people, that as they were the conquerors, so they were the surveyors of the world. Every new war produced a new survey and itinerary of the countries which were the scenes of action; so that the materials of geography were accumulated by every additional conquest. Some fragments of the itineraries thus composed still remain. The most memorable is that which bears the name of Antoninus, and which may be described as a mere skeleton road-book, exhibiting nothing more than the names of places, and their distances from each other. The Jerusalem Itinerary, which details minutely the route from Bordeaux to that holy city, is of the same description.

A more remarkable monument, however, is the *Peutingerian Table*, which forms a map of the world, constructed on the most singular principles. The map is twenty feet long and only one foot broad, so that we can easily conceive how incorrectly the proportion of the different parts is exhibited. Along the high road which traverses the Roman empire in the general direction of east and west, objects are minutely and accurately represented; but of those objects which lie to the north and south of it, only some general notion is conveyed. The Peutingerian Table serves as a specimen of what were called *Itinera Picta*, the "painted roads" of the ancients, intended for the clearer direction of the march of their armies.

While the Romans by their surveys contributed much to increase the mass of materials out of which the structure of geographical science was to be reared, they never attempted themselves to combine these materials into one harmonious system. They imbibed in no degree the commercial spirit of the great maritime states of the ancient world, Carthage, Greece, and Egypt, which their valour and discipline obliged to submit to their dominion. But whilst the trade of the conquered countries continued to be carried on through nearly the former channels after they were reduced to the form of Roman provinces, the wealth accumulated in the capital of the world gave rise to a demand for luxuries of every description. This, combined with the comparative peace and security which for a long time prevailed after the complete establishment of the Roman dominion, gave new vigour to commercial enterprise. Alexandria continued the great centre of naval affairs. Obstacles which in the time of Alexander were deemed insurmountable, were completely overcome. Trade with India through Egypt acquired new energy, and was carried on to a greater extent. Continued intercourse with the shores of India at length made known to navigators the periodical winds which prevail in the Indian Ocean; and taking advantage of these, pilots were emboldened to abandon the slow and dangerous course along the coasts, and to make the open sea their highway. Their course was from Ocelis, at the mouth of the Arabian Gulf, to Nelkunda (Nelisuram), on the western shores of the Indian continent (the coast of Malabar), which seems to have been the utmost limit of the ancient navigation in that quarter of the globe. The extensive regions which stretch beyond this to the east were very imperfectly known by the reports obtained from a few adventurers who visited them by land.

If we now bring into one view the amount of information possessed by the ancients respecting the habitable globe, we shall find that it was extremely limited. It was at those places on the earth where the human mind displayed greatest activity and enterprise that this knowledge was naturally accumulated. Proceeding from these stations, the boundary which separated the known from the unknown part of the world was gradually enlarged; but the regions comprehended within it constituted still but a small portion of the whole. In Europe the extensive provinces in the eastern part of Germany were but little known, while the whole of that vast territory which now forms the countries of Denmark, Sweden, Prussia, Poland, and Russia, was buried in the deepest obscurity. The inhospitable and dreary climes within the arctic circle were yet unexplored. In Africa little was known beyond the countries stretching along the Mediterranean Sea, and those bordering on the western shore of the Arabian Gulf. In Asia the rich and fertile countries beyond the Ganges, whence the commerce of modern times has drawn the most valuable commodities for the comfort and embellishment of civilized society, were known, if known at all, only by the most vague and uncertain reports. The immense regions on the north occupied by the wandering tribes called in ancient times by the general names of Sarmatians or Scythians, and which are now inhabited by various tribes of Tartars, and by the Asiatic subjects of Russia, seem never to have been penetrated. Add to this, that the fertile and populous regions within the torrid zone were imagined to be uninhabitable; and we have ample proof that the geography of the ancients was very imperfect.

Having thus far given a succinct view of the progressive steps by which the earth's surface, considered merely as tracts of territory inhabited by men, gradually became known, it will be proper next to trace briefly the advances made towards arranging into a systematic form the materials accumulated. Science required that the relative positions of places, with their distances from each other, should be ascertained in such a manner as to furnish fixed principles on which the whole, or any portion, of the surface of the earth might be represented or delineated with due regard to its figure and dimensions.

The first rude attempt made by the early geographers to determine the position of places appears to have depended on the division of the earth into *climates*, distinguished by the species of animals and plants produced in each. Thus the appearance of the negro, the rhinoceros, and the elephant, suggested to them the line of division where the torrid zone began towards the north, and ended towards the south. But instead of this very vague method, another was soon adopted, which consisted in observing at places the length of the longest and shortest day. This was determined with some accuracy by means of a *gnomon*, a method of observation much used by the ancients. An upright pillar of a known height being erected on a level pavement, by observing the lengths of the meridian shadows, they were enabled to trace the progress of the sun from tropic to tropic. The most ancient observation with the gnomon which we meet with is that of Pytheas, in the days of Alexander the Great. Pytheas observed at the summer solstice at Marseilles, that the length of the meridian shadow was to the height of the gnomon as 213$\frac{1}{8}$ to 600; an observation which makes the meridian altitude of the sun at Marseilles on that day 70° 27′. The merit of the invention of the gnomon in Greece is ascribed to the astronomical school of Miletus, and particularly to Anaximander and Anaximenes. There is reason, however, to believe that this method of observation was originally invented by the Egyptians; and that Thales, who travelled into Egypt, carried thence the knowledge of it into Greece. It has even been conjectured that the Egyptian pyramids and obelisks were intended for the same purpose with the gnomon; and, though it would be extravagant to imagine that this was their sole use, this opinion appears to be countenanced by the fact of their being placed in the direction of the four cardinal points.

The determination of the length of the meridian shadow at the solstices for different parts of the earth, by observations made with the gnomon, is important as being the first step towards connecting geography with astronomy; and, when combined with just conceptions of the globular figure of the earth, leads, by a simple train of thought, to the notion of latitude by which the position of a place is fixed relatively to north and south. The position with regard to east and west is the only other element necessary for fixing the absolute situation of the place on the surface of the earth. It might have been supposed not to be more than a reflecting mind could easily accomplish, to reach the conception of both these elements, and to apply them to use. Yet so slow was the progress towards the apprehension of the principles on which an accurate system of geography might be founded, that from the days of Thales and his immediate successors, who flourished in the sixth century before the Christian era, there appears to have been little done for the improvement of geography, as a science, until the establishment of the famous astronomical school of Alexandria. Pythagoras had indeed maintained the true system of the world, by placing the sun in the centre, and giving the earth both a diurnal and annual revolution; but this doctrine was so much in advance of the age in which he promulgated it, that it was soon lost sight of.

Eratosthenes was the first who reduced geography to a regular system, and laid its foundations on clear and solid principles. Under the patronage of the Ptolemies, he had access to the materials collected by Alexander, his generals and successors, as well as to the immense mass of documents accumulated in the Alexandrian library. At an early period of the history of astronomical science, the vulgar opinion that the earth is a flat surface, with the heavens resting upon it as a canopy, was rejected; but it was not at once that distinct conceptions of its globular figure were acquired. It was only as astronomical observations increased that the doctrine of its sphericity was fully established. This point had been gained when Eratosthenes began his labours; and what he endeavoured to accomplish was to delineate, in strict conformity with this principle, the known parts of the earth's surface.

With this view, founding his system on the use of the gnomon, he supposed a line to be traced through certain places, in all of which the longest day was known to be exactly of the same length. This line would evidently be a parallel to the equator. But though his method was correct in principle, the want of accurate observations rendered it uncertain in practice. The line was supposed to comprise all the leading positions which lay near it, though they did not actually come within its range. Its western extremity was the Sacred Promontory of Iberia (Cape St Vincent); thence it passed through the Straits of Gades. Proceeding eastward, it passed through the Sicilian Sea, and near the southern extremity of the Peloponnesus, and was continued through the island of hodes, and the Bay of Issus; whence entering Cilicia, nd crossing the Euphrates and the Tigris, it was extended to the mountains of India, and terminated at the remote ty of Thinæ, situated on the Eastern Ocean. The pallel thus drawn was understood to pass through all those aces where the longest day was fourteen hours and a half. stretched the whole length of what was supposed to be e habitable world, and measured about 70,000 stadia; distance corresponding, according to the estimate of ratosthenes, to about 140 degrees, which is rather more an one third of the circuit of the globe.

This first parallel drawn through Rhodes was ever afrwards preferred as the basis of ancient maps; inasuch as it was traced through the middle of the Mediranean, along the coasts of which were situated the incipal nations of antiquity. Following out the same ppy thought which he had thus successfully made the oundwork of his system, Eratosthenes was induced not ly to trace other parallels at certain intervals from the st, as one through Alexandria, another through Syene, d a third through Meroe; but also to trace, at right gles to these, a *meridian*, passing through Rhodes and exandria southward to Syene and Meroe. As the progress hich he thus made towards the completion of what he d so skilfully conceived, naturally tended to enlarge s ideas concerning geographical science, he attempted at seemed a still more difficult undertaking, namely, determine the circumference of the globe by the actual asurement of a segment of one of its great circles. e method he pursued has already been pointed out in e article ASTRONOMY, page 730. There is a differce among ancient authors respecting the result obned by Eratosthenes. The great majority, however, te it to be 252,000 stadia, which give exactly 700 sta for a degree of the equator, and 555 stadia for the gree of longitude upon the parallel drawn through odes.

The knowledge of the circumference of the earth is a cessary element in the construction of maps; and hence e most eminent of the ancient astronomical geograers made repeated endeavours to determine it with acracy. Possidonius, by an astronomical observation, demined the arch of the meridian between Rhodes and exandria to be a forty-eighth part of the whole circumence. With regard to the distance between these two ces, 5000 stadia were the reputed distance; but Eratosnes had made it only 3750 stadia upwards of 170 years fore, and betwixt these two Possidonius had to make oice. The former number gives 240,000 stadia for the ole circumference, the latter 180,000 stadia. Of this t result, which gives 500 stadia for a degree of the equa, Possidonius is reported by Strabo to have approved. r want of the knowledge of the true length of the stam, it is now impossible to judge of the actual quantity igned either by Eratosthenes or Possidonius as the meae of the earth's circumference; but the great uncerty about the distance between the points of observa in the case of the determination of the latter astroner renders his conclusion of no value.

Notwithstanding the soundness of the principles which l now been laid down for the delineation of the globe, ch remained to be done, in the way of observation, be an accurate representation of the whole, or a portion the earth's surface, could be given. Both the latitudes l longitudes of the ancients are erroneous; more espelly the latter. This is what might be expected at that ly period. But in setting out from the Sacred Promony of Iberia, the meridian of which the ancients made ir first meridian, the errors in longitude accumulate, as advance eastward, with a regularity, as well as rapidity, ich is very surprising. The regularity of their increase induced M. Gosselin to conclude that they were to be attributed, not to the imperfection of independent observations, but to some general cause, which he endeavoured to assign by imagining that Eratosthenes had access to some early map, found probably by Alexander or his generals in some country in the East, where astronomy had been successfully cultivated; and that misapprehensions respecting the principle of delineation employed, which M. Gosselin supposes to have been that on which the plane chart is constructed, had led him into a regular system of errors. In the plane map the length of a degree of longitude is supposed to be the same at all distances from the equator. By taking for granted that Eratosthenes took his distances from a map of this kind, on which the parts of the globe had been accurately laid down, but that he divided the stadia expressing these distances, not by 700, the number of stadia in a degree at the equator, as he ought to have done, but by 555, the number corresponding to the parallel of Rhodes, M. Gosselin obtains results which have a wonderful coincidence with the positions actually given by Eratosthenes. These results, however, are deduced from a hypothesis which is unsupported by any evidence, except what may be supposed to arise from this coincidence. A more probable solution seems to be that Eratosthenes determined his longitudes from the itinerary measures, which he reduced to degrees at the rate of 700 stadia to a degree at the equator, and of 555 to a degree at the parallel of Rhodes; and that the errors are the consequences of the exaggerated accounts which merchants and travellers of that age gave of the distances over which they passed;—their exaggerations, of course, bearing some proportion to the length and hardships of the journeys undertaken.

The knowledge as yet possessed by geographers with regard to the outline of the habitable globe was far from being such as to enable them to delineate it with any degree of precision. This circumstance, combined with the unavoidable errors in latitude and longitude, produced very great distortions in the representations given of the countries on the surface of the globe. Under the guidance of sound principles of science, however, it was now certain that these imperfections would gradually disappear.

The improvements introduced into geography by Eratosthenes were perfected in principle by Hipparchus. This celebrated astronomer, who flourished between a hundred and sixty and a hundred and thirty-five years before the Christian era, was the first who undertook the arduous task of forming a catalogue of the stars, and fixing their relative positions. His object was to transmit to posterity a knowledge of the state of the heavens at the period of his observations. The extremities of the imaginary axis round which the heavens perform their diurnal revolution suggest two fixed points by which the position of the great circle of the celestial sphere called the equator is determined. If a great circle be supposed to pass through these points and any star, the position of the star will be ascertained if we measure in degrees and parts of a degree the arch of the meridian circle intercepted between the star and the equator, and also the arch of the equator intercepted between a given point in it, and the meridian circle passing through the star. Upon this principle did Hipparchus arrange the stars according to their places in the heavens, a work in which he appears, however, to have been in some measure anticipated by Timocharis and Aristillus, who began to observe about two hundred and ninety-five years before the Christian era. The great improvement which he introduced into geography consisted in this, that he applied to the determining of the position of any point on the surface of the earth the same artifice which he had already so happily introduced in the arrangement of the constellations; and thus furnished the means of ascertaining the relative situations of places with a precision which no itinerary measurements could possibly attain. If we suppose the earth to be a globe concentric with the celestial sphere, and intersected by the planes of the celestial equator and meridian, the principle on which the application of this artifice to the terrestrial sphere depends becomes at once obvious. Hipparchus made a considerable number of observations of latitude, and pointed out how longitudes might be determined by observing the eclipses of the sun and moon. Great as this improvement was, its importance seems not to have been duly estimated until the days of Ptolemy; for none of the intermediate authors, such as Strabo, Vetruvius, and Pliny, have given the least hint of the latitude and longitude of any one place in degrees and minutes, though all of them have given minutely the geographical position of places according to the length and shadows of the gnomon. Strabo, indeed, even justifies his neglect of the astronomical principles introduced by Hipparchus. "A geographer," says he, "is to pay no attention to what is out of the earth; nor will men engaged in conducting the affairs of that part of the earth which is inhabited, deem the distinction and divisions of Hipparchus worthy of notice."

The true principles of geography being pointed out by the application of latitude and longitude to places on the earth, the way was opened for the improvement of maps, which, with the single exception of the map drawn by Eratosthenes, had hitherto been little more than rude outlines and topographical sketches of the different countries.

No maps more ancient than those formed to illustrate Ptolemy's geography have reached modern times; but the earliest of which there is any account are those of Sesostris, of whom it is said, that having traversed great part of the earth, he caused his marches to be recorded in maps; and that he gave copies of these maps not only to the Egyptians, but to the Scythians, whose astonishment he thus greatly excited.

Some have imagined that the Jews made a map of the Holy Land when they gave the different portions to the nine tribes at Shiloh. For on that occasion, as we are informed by the sacred historian, men were sent "to walk through the land, and to describe it:" and when they had accomplished the object of their mission, by describing "it by cities into seven parts, in a book," they returned unto Joshua. What is here said, however, does not fully determine whether their mensuration of the land was only recorded in numbers, or regularly projected and digested into the form of a map.

The first Grecian map on record is that of Anaximander, mentioned by Strabo, which some have conjectured to have been a general map of the then known world. It has further been imagined to be the same with that referred to by Hipparchus under the designation of *The Ancient Map*, and which in some few particulars he preferred to that of Eratosthenes.

But some idea of the nature of the maps of those early days will be best obtained from the map of Aristagoras, king of Miletus, which is minutely described by Herodotus. The historian tells us that this map, which was traced on brass or copper, Aristagoras showed to Cleomenes, king of Sparta, in order to induce him to attack the king of Persia, even in his palace at Susa, for the purpose of restoring the Ionians to their ancient freedom. It contained the intermediate countries to be traversed in that march. We must not interpret, however, the words of Herodotus too literally, when he describes it as containing "the whole circumference of the earth, the whole sea or ocean, and all the rivers." Keeping in view the state of geography at that period, it may justly be concluded, that notwithstanding this pompous form of expression, *the sea* meant only the Mediterranean, and therefore *the earth* or land the coasts of that sea, and more particularly Asia Minor, extended towards the middle of Persia: by *the rivers* must be meant the Halys, the Euphrates, and the Tigris, which Herodotus mentions as necessary to be crossed in the expedition in question. The map contained one straight line, called the *royal highway*, embracing all the stations or places of encampment between Sardis and Susa, so that it was properly an itinerary.

The principle on which Eratosthenes constructed his map we have already considered. With regard to its extent, it seems to have contained little more than the states of Greece, and the dominions of the successors of Alexander, digested from the surveys of the marches of that great general. He had some faint idea respecting the western parts of Europe, which he had acquired from the voyage of Pytheas; but not such a conception as to enable him to delineate their outline on a chart. According to the report of Strabo, he was quite unacquainted with Spain, Gaul, Germany, and Britain, he was equally ignorant of Italy, the coasts of the Adriatic, Pontus, and of all the countries toward the north. His errors with regard to the distances of places were in some instances enormous. The distance of Carthage from Alexandria he represents at 15,000 stadia, instead of 9000.

It was not until Ptolemy commenced his labours that the improvements pointed out by Hipparchus were effectually applied to perfect the system which Eratosthenes had so happily begun. Ptolemy composed his system of geography, which escaped amidst the general wreck which has consumed so many other ancient books of science, in the reign of Antoninus Pius, about 150 years after the opening of the Christian era. At this period the Roman empire had reached its utmost extent, and all the provinces had been surveyed, and were well known. The materials then in existence, and in the possession of Ptolemy for completing his great work, were the proportions of the height of the gnomon and its shadow, at the time of the equinoxes and solstices, taken by different astronomers; calculations founded on the length of the longest days; the measures or computed distances of the principal roads contained in the surveys and itineraries; and the various reports of travellers and navigators, whose determinations of the distances of places often rested, however, on no better foundation than hearsay and conjecture. Among these various particulars, there evidently existed considerable differences in point of authority. But Ptolemy undertook the difficult and laborious task of comparing, and reducing into one system, which should possess the order and beauty of science, this apparently incongruous mass. He converted and translated the whole into a new mathematical language, expressing in degrees and minutes the latitude and longitude of each place, according to the principles laid down by Hipparchus, but which had been allowed by geographers to lie useless for upwards of two hundred and fifty years. It is in Ptolemy's work, which consists of eight books, that we find for the first time the mathematical principles of the construction of maps, both general and particular, as well as of several projections of the sphere.

Notwithstanding that the light of accurate science thus directed the steps of the first geographer of antiquity, he was far from reaching the precision at which he aimed. This arose from the imperfection of the original materials upon which his work is based in reference to its details. With regard to the remoter boundaries of the then known world, in all its quarters, a wonderful advancement in knowledge had been made since the days of Eratosthenes and of Strabo. But still that additional information was not fitted to make up for the want of astronomical observations, by which alone accuracy could be secured. Besides, in relation to places situated beyond the limits of the Roman empire, and therefore out of the range alike of astronomers and surveyors, it was almost impossible for Ptolemy not to commit mistakes. Thus his errors arose from the ignorance of the age; and are of such a character as to admit of being removed only as opportunities are afforded of obtaining the requisite data by the strict application of the principles derived from mathematical and astronomical science.

Ptolemy adopted the measure of a degree at 500 stadia, according to the standard of Possidonius, instead of following the measurement of Eratosthenes, which gives 700 stadia to a degree. But M. Gosselin has accused him of an error of a more serious kind; because, if really committed, it would have indicated a strange neglect of what a geographer should make his first care. This error consists in assuming one measure for the degree of latitude (the measure of Eratosthenes, 700 stadia) and another for the degree of longitude at the equator. Such a hypothesis would evidently be inconsistent with the globular figure of the earth. It may reasonably be doubted, however, whether M. Gosselin's accusation is well founded; for, though it seems supported by the fact, that while Ptolemy has changed materially all the longitudes of Eratosthenes, the latitudes along the great line remain the same, and are in general correct, this circumstance may be accounted for sufficiently from other causes. Rhodes, and several other points of this great line, were fixed with regard to latitude by observations approximating to the truth, while the elements for determining the longitudes were derived entirely from the itineraries. To the north and south of the great central line, which alone was fixed upon sound data, errors in latitude accumulate as rapidly as those in longitude are found to do in proceeding eastward.

One of the most remarkable errors in the geographical work of Ptolemy is the great length assigned to the Mediterranean. Reckoning from the Straits of Gades to the bottom of the Bay of Issus, where Alexandretta, or Sanderoon, now stands, he makes the difference of longitude no less than sixty-two degrees, which is upwards of twenty and a half degrees above the truth. This amazing error, which affected all our maps more or less until the beginning of the last century, was produced in consequence of his having put too much confidence in the supposed surveys of different persons of reputation recorded by Strabo, and who appeared to confirm the accuracy of each other's computation. According to their united testimony, the whole length of the Mediterranean was about 2500 stadia, which, being converted into degrees of longitude according to the method of Ptolemy, of allowing 4 stadia to a degree of longitude on the parallel of Rhodes, give about 66° 15′. This is 4° 15′ more than what are given by Marinus, whom in this particular Ptolemy strictly follows.

Pliny quotes from Agrippa a computation of the length of the Mediterranean, which makes it 3440 Roman miles; but in quoting it he adds a suspicion that there is an error in the numbers. When converted into degrees of longitude, the result of this computation gives 58° 20′. As, however, the length given by Strabo amounted, as we have seen, to 66° 15′, Ptolemy seems to have chosen a middle path between these two erroneous computations, and to have adopted 62° for the difference of longitude in question. But there is another ancient computation quoted also by Pliny from Polybius, according to which the length of the Mediterranean is stated to be 2440 Roman miles. Had Ptolemy followed this estimate, he would have obtained for a result 41° 4′, which is not far from the truth.

Thus we see that the circumstances under which Ptolemy wrote rendered it impossible for him to avoid mistakes, and that he might be misled even when more accurate results were within his reach.

The great obstacle with which the ancients had to contend was the finding of the longitude with accuracy, a problem for the solution of which it was long before there was discovered any method sufficiently exact. This accounts for the erroneous longitudes of Ptolemy, and more especially for the length of time, even many centuries, during which the remarkable error with regard to the length of the Mediterranean remained undiscovered and uncorrected.

We have now traced the history of geography from the earliest period of which we have any information, to the time when it assumes a scientific character. We shall conclude our account of ancient geography by shortly noticing the principal geographers of antiquity, some of whom have not yet been mentioned, while others have only been quoted in tracing the rise and progress of the science.

The intimate connection between geography and the sciences of geometry and astronomy, rendered the former an object of attention to many who anciently cultivated the latter. We have already mentioned Anaximander and Anaximenes, of the school of Miletus. Democritus, Eudoxus of Cnidus, and Parmenides, are also reported to have improved geography; and to the last is attributed the division of the earth into zones. These were followed by Eratosthenes, who lived about two hundred and forty years before the Christian era; by Hipparchus about eighty years afterwards; by Polybius, Geminus, and Possidonius. Eratosthenes wrote three books on geography, some passages of which Strabo criticises, though he frequently defends him against Hipparchus, who appears to oppose his opinions with some degree of affectation. Polybius also wrote on geography; as did likewise Geminus and Possidonius, who are frequently quoted by Strabo. Polybius, according to Geminus, argued with considerable acuteness for the possibility of the torrid zone being inhabited; and he even adduced plausible arguments to prove that the countries under the equator enjoy a more temperate climate than the countries do that are situated near the tropics.

We must not here omit a geographer and geometer who lived about the time of Alexander the Great. This was Dicearchus of Messina, a disciple of Theophrastus, who wrote a description of Greece in iambic verses, of which some fragments yet remain. But what chiefly renders him remarkable is, that he measured geometrically several mountains, to which an excessive height had been before assigned.

With Dicearchus we may notice another geometer, Xenagoras, a disciple of Aristotle, mentioned by Plutarch in his life of Paulus Æmilius, who occupied himself in the measurement of mountains. He found the height of Mount Olympus to be fifteen stadia.

In some of the latter periods which preceded the Christian era there were several writers on geography, as Artemidorus of Ephesus, who wrote a geographical work of eleven books, of which nothing remains; Scymnus of Chio, author of a description of the earth in iambic verses, which remain in a very mutilated state; Isidorus of Charax, who gave a description of the Parthian empire; and Scylax of Caryades, author of a voyage round the Mediterranean, which is still extant.

The works of all these geographers are, however, but small in comparison with the Geography of Strabo; a work in seventeen books, which has come down to us entire. This is one of the most valuable works of antiquity, both from the spirit of discussion which runs through it, and the number of curious particulars which the author has collected from different geographers and navigators who preceded him, and of whose works nothing remains except these extracts. Strabo lived in the reigns of Augustus and Tiberius, and was nearly contemporary with Pomponius Mela. This latter geographer wrote a work *De Situ*

Orbis, which, though little more than a bare summary, is valuable as it gives us a sketch of what was known in his time respecting the state of the habitable globe. Besides Mela, Rome produced in the most flourishing era of its literature another eminent geographer, Pliny. He devoted two books of his extensive work on natural history to a system of geography. His intimate connection with the imperial family, and with many of the most eminent commanders of the time, appears to have given him access to all the military measurements, as well as to the general survey of the Roman empire. Thus furnished with a greater store of authentic materials than any former writer, he has introduced a great number of itinerary details, which are for the most part accurate and valuable. Julius Solenus has also treated of geography in his *Polyhistor*, a compilation sufficiently valuable from the number of curious particulars which are there collected. Marinus of Tyre was another geographer who appears to have been distinguished, though his works have perished. Even under the Roman empire Tyre continued to be the seat of an extensive commerce; indeed the commercial relations of her citizens appear to have extended over a wider portion of the earth's surface than ever. The enlarged materials furnished by the lengthened journeys of his countrymen, which brought them even to the confines of China, Marinus collected, and sought to apply to them the astronomical principles of Hipparchus, so that he might give to geography a new and more accurate form. Ptolemy, whom Marinus preceded by a short time, employs a great part of his first book in discussing the means employed by the Tyrian geographer for fixing the relative position of places; and from the references and extracts it appears that the system of Marinus partook largely of the imperfections of a first effort.

The enlarged and scientific views of Ptolemy we have already considered. Some time after Ptolemy lived Dionysius, commonly called the *Periegetic*, from the title of a work in verse composed by him, namely, his *Periegesis*, or Survey of the World. This work was translated into Latin verse by Priscianus, and afterwards by Avienus. There is, besides, a description by Avienus, of the maritime coasts, in iambic verses, of which there remain about seven hundred.

The difficulty of procuring the small and scattered pieces of most of these authors, with those of a few others not here enumerated, induced the learned Hudson to collect them into one work, consisting of four volumes octavo, which were published in the years 1698, 1702, 1712, under the title of *Geographiæ veteris Scriptores Græci minores.* The originals are accompanied with Latin translations, and notes and dissertations on each by Dodwell. This is a very valuable collection.

We now proceed to consider the progress of geography during the middle ages. From the days of Ptolemy to the revival of letters in Europe, little was done for its solid improvement. The calamities that ere long overwhelmed the Roman empire, involved in the general progress of the intellectual darkness which settled on the world even the imperfect knowledge possessed by the ancient geographers. While barbarous nations poured in from several quarters, art and science ceased to be cultivated. The union by which the Roman power had bound together mankind being now dissolved, Europe was divided into small and independent, and for the most part hostile communities, which had but vague conceptions respecting the situation of each other, while no intercourse subsisted between their members. With regard to remote regions all knowledge was lost; their situations, their commodities, and almost their names, were unknown.

Amidst this ignorance there were but few channels open through which knowledge could be obtained. One circumstance, however, prevented commercial intercourse with foreign nations from being altogether suspended. The opulence and luxury of imperial Rome had long given life and energy to commercial enterprise: that stimulus was now withdrawn; but Constantinople still remained, the last refuge of ancient arts, and taste, and elegance, when the rest of Europe was overspread with barbarism. Fortunately that city had escaped the destructive rage of the fierce invaders; and there, under the cherishing influence of a demand for foreign productions and luxuries, commerce continued to flourish. Alexandria continued to be the emporium whence they imported the commodities of the East Indies, until Egypt, falling under the power of the Arabians, ceased to be a province of the Roman empire. After this event the industry of the Greeks succeeded in discovering a new channel by which Constantinople might still be supplied with the productions of India. These were first conveyed up the Indus as far as that river is navigable, thence by land-carriage they were brought to the Oxus, and were carried down that river to the Caspian Sea. Entering there the Volga, they were conveyed up it, and thence were again transported by land until they reached the Tanais, down which they were conveyed to the Euxine Sea, where vessels from Constantinople awaited their arrival. By this circuitous route was a channel of intercourse kept open with the most distant countries of the East; and an extensive knowledge of remote regions was still preserved in the capital of the Greek empire, while the rest of Europe was sunk in the grossest ignorance.

The missions sent for the conversion of the northern pagans to Christianity served somewhat to illustrate the geography of Europe; though there is sufficient proof that the monks employed were, in many instances, themselves grossly ignorant, some not even knowing the capital of their own country, or the cities nearest to their own. Something was also done by the great sovereigns of Europe towards dispelling the prevailing ignorance of the age on matters connected with geography. Nor did the piratical exploits of the Danes and Norwegians under their great sea-kings fail to make them acquainted with the seas and maritime coasts where they carried on their devastations. But it was in the East that a gleam of light and knowledge began to appear, which seemed to be the harbinger of the noon-day splendour of science, that should dispel the darkness of ignorance which had so long oppressed the human mind. Under the influence of a fanaticism which prompted them to own no law but the koran and the sword, the followers of Mahomet had rushed from the heart of Arabia, and had carried their conquests over half the world. At length, however, under a race of humane and polished princes, having contracted a relish for the sciences of the people whose empire they had contributed to overturn, they stood for some time distinguished as the most learned of nations. They translated into their own language the books of several of the Greek philosophers. The valuable work of Ptolemy was one of the first; and hence the study of geography became an early object of their attention. But the advancement which the science made in their hands towards precision was slow; for they copied and retailed all Ptolemy's principal errors. Still, in all the countries that were under Mahommedan dominion numerous observations were made, which, though not always strictly correct, were entitled to be considered as a step beyond the calculations made merely from the itineraries by the Alexandrian geographers. In the beginning of the ninth century, under their caliph Almamon, who may rank among the most distinguished patrons of science that ever filled a throne, they measured a degree of latitude on the plains of Sinjar, or Shinar, near Babylon, with a view to determine the cirumference of the earth. The tables of Abulfeda and lug Beg, and of Nazir Eddin, edited by Grævius, and published by Hudson, furnish materials that are still of se in the construction of the maps of the interior of Asia.

The progress and success of the Moslem arms removed e obscurity in which many countries had until then been ncealed, as well as the barbarism in which they had been nk. And even beyond the limits of the Mahommedan orld they pushed their researches, by sending missions oth to the east and to the west, which they explored their remotest limits. At that time Europe remained norant of the improvements made by the Arabians, ough she was destined in subsequent ages to perfect eir discoveries.

At length the long period of barbarism which accomnied and followed the fall of the Roman empire, dung which the traces of whatever had embellished soety, or contributed to the comfort and convenience of e, were almost entirely effaced, drew to a close. Inustry began again to shed its blessings on mankind, d Italy was the country where its benign influences ere first perceptible. Having from the operation of vaous causes again obtained liberty and independence, the alians soon began to feel the impulse of those passions hich serve most powerfully to arouse men to activity and terprise. The reviving demand for the comforts and xuries of life led to the revival of foreign commerce. he valuable commodities of the East were at first obined at Constantinople. But the exorbitant price dended at that mart, in consequence of the circuitous ute by which they were conveyed thither, induced the alians to resort to other ports, as Aleppo and Tripoli, the Syrian coast, and at length to Egypt itself. After e Soldans had revived the commerce with India in its cient channel by the Arabian Gulf, Venice, Genoa, sa, rose from inconsiderable towns to wealthy and polous cities. Their trade extended to all the ports in e Mediterranean, and even beyond the straits to the wns on the coasts of Spain, France, the Low Countries, d England; and from these points they diffused through rope a taste for the luxuries and enjoyments of civied life, which they at the same time furnished the eans of gratifying.

It was not long ere an event occurred, the most extralinary perhaps in the history of human society, which ve a new impulse to the European mind, and forcibly ected its view eastward to the regions of Asia. Under influence of a high-wrought enthusiasm, the martial rit of the Europeans was aroused, and vast armies, mposed of all the nations of Christendom, marched tords Asia on the wild enterprise of delivering the Holy nd from the dominion of Infidels. The crusades, hower blind the zeal from which they took their rise, had a y favourable influence on the intellectual state of Eupe, and prepared it for receiving the light of science ich was soon to dawn upon it. Interesting regions, own hitherto only by the scanty reports of ignorant and dulous pilgrims, were now made the object of atten and research. Not only was the way opened for the ropean nations acquiring a correct knowledge of the ly Land, with the kingdoms of Jerusalem and Edessa, nded by the victorious crusaders; but the extensive ions over which the Saracens and the Turks had exded their empire began to be explored. Search was w made in the writings of the ancient geographers; nor t improbable that some light was derived even from Arabian writers. Religious zeal, the hope of gain, mbined with motives of mere curiosity, induced seve persons to travel by land into remote regions of the st, far beyond the countries to which the operations of crusaders extended. Prompted by superstitious veneration for the law of Moses, and by a desire of visiting his countrymen in the East, whom he hoped to find possessed of wealth and power, Benjamin, a Jew of Tudela, in the kingdom of Navarre, set out from Spain in the year 1160, and travelling by land to Constantinople, proceeded through the countries to the north of the Euxine and Caspian Seas. He then journeyed towards the south, and traversed various provinces of the further India, until, having reached the Indian Ocean, he embarked and visited several of its islands; and at length, after thirteen years, returned by the way of Egypt to Europe. In his progress he had acquired much information respecting a large portion of the globe, then altogether unknown to Europeans.

Various missions were sent by the pope and by Christian princes, for purposes which led them to traverse the remote provinces of Asia. Father John de Plano Carpini, at the head of a mission of Franciscan monks, and Father Ascolino, at the head of another mission of Dominicans, were in the year 1246 sent by Innocent IV. to enjoin Kayuk Khan, the grandson of Zengis, who was then at the head of the Tartar empire, to embrace Christianity, and to cease from desolating the world by his arms. In fulfilling the commands laid upon them by the head of the Christian church, the mendicants had an opportunity of visiting a great part of Asia. Carpini, having taken his route through Poland and Russia, travelled through the northern provinces as far as the extremities of Thibet; whilst Ascolino, who appears to have landed somewhere in Syria, advanced through the southern provinces into the interior parts of Persia.

Father William de Rubruquis, a Franciscan monk, having been sent in the year 1253 on a mission by St Louis of France, in search of an imaginary personage, a powerful khan of the Tartars, who was reported to have embraced the Christian faith, made a circuit through the interior parts of Asia more extensive than that of any European who had hitherto explored them. He had the merit of being the first modern traveller that gave a true account of the Caspian, which had been correctly described by the early Greeks as an inland separate sea; but a notion afterwards prevailed that it was connected with the Northern Ocean. Rubruquis ascertained that it had no connection with the ocean or any other sea. The account of his journey was so little read, however, that the old error was repeated in books of geography long after his time.

While the republics of Italy, and, above all, the state of Venice, were engaged in distributing the jewels, the spices, and the fine cloths of India over the western world, it was impossible that motives of curiosity, as well as a desire of commercial advantage, should not be awakened to such a degree as to impel some to brave all the obstacles and dangers to be encountered in visiting those remote countries where these precious and profitable commodities were produced. A considerable number accordingly are recorded as having penetrated a greater or less depth into the interior of Asia. But of all the old travellers the fame is eclipsed by that of Marco Polo, who has always ranked among the greatest discoverers of any age. This extraordinary man was a noble Venetian, whose family, according to the custom of his country, engaged in extensive commerce. Nicolo Polo, and Maffeo Polo, the father and uncle of Marco, were merchants, who, in partnership, traded chiefly with the East; and in pursuit of their mercantile speculations had already visited Tartary. The recital of their travels on their return fired the youthful imagination of Marco, then between seventeen and eighteen years old. Having, when in the East, gained the confidence of Kublai Khan, the great conqueror of China, at whose court they had resided for a long time, he had sent them back to Italy, accompanied by an officer of his court, that they might repair to Rome as his ambassadors to the pope, of whom, and the potentates of the western world, they had given him an ample account. After many delays they were now, about the year 1265, to set out on their return to the court of Kublai, bearing the papal letters and benediction; and it was resolved that young Marco should accompany them. After a journey that occupied no less than three and a half years, and in the progress of which they passed through the chief cities in the more cultivated parts of Asia, they reached Yen-king, near the spot where Pekin now stands, where they were honourably and graciously received by the grand khan. Struck with the appearance of young Marco, the khan condescended to take him under his protection, and caused him immediately to be enrolled among his attendants of honour. By prudence and fidelity Marco gained so high a place in the esteem and confidence of his protector, that for seventeen years, during which he remained in his service, he was employed in confidential missions to every part of the empire and its dependencies. He made more than one voyage on the Indian Ocean, and traded with many of the islands. Besides what he learned from his own observation, he collected from others many things concerning countries which he did not visit. Considering the very favourable circumstances in which he was placed for geographical research, as well as his passion for travelling, which seems to have increased with his opportunities of gratifying it, it is not surprising that, after the long period of his wanderings in Asia, he should have returned to Europe possessed of the knowledge of many particulars, until his time unknown, respecting the eastern parts of the world. Marco, being afterwards made a prisoner by the Genoese, was induced, with a view to beguile the tediousness of his confinement, to dictate a narrative of his travels. His information was so far in advance of the age, that his veracity was exposed to the most injurious suspicions. But, if we make allowance for some tincture of credulity, characteristic of the times in which he lived, his narrative is supported in all its essential points by modern information.

While great accessions were thus made to the stock of knowledge possessed by the nations of Europe respecting the habitable globe, their ideas were at the same time gradually enlarged; and an adventurous spirit was generated, which prepared them for attempting further discoveries. Still their efforts were limited by certain bounds, in consequence of the imperfect state of navigation. Whatever conceptions a daring mind might venture to form respecting the existence of unknown regions, separated from the known continents by the mighty expanse of the Atlantic Ocean, mankind had not yet so obtained the dominion of the sea as to be able to bring such conceptions to the test of experiment. It was not until the fortunate discovery of the polarity of the magnetic needle, and the consequent construction of the mariner's compass, that man was enabled to visit every part of the globe which he inhabits. This important discovery was made by Flavio Gioia, a citizen of Amalfi, a town of considerable trade in the kingdom of Naples, about the year 1302. Encouraged by the possession of this sure guide, by which at all times and in all places he could with certainty steer his course, the navigator gradually abandoned the timid and slow method of sailing along the shore, and boldly committed his bark to the open sea. At the commencement of the fifteenth century, however, navigation appears to have advanced very little beyond the state which it had reached before the downfall of the Roman empire. But it was now destined to make rapid progress. The growing spirit of enterprise, combined with the increasing light of science, had prepared the states of Europe for entering upon that great career of discovery, of which the details constitute the materials for the history of modern geography.

Portugal took the lead in this new and brilliant path. Her first attempt was to discover the unknown countries situated along the western coast of Africa. Notwithstanding the vicinity of that great continent, and the strong inducement afforded, in the fertility of the countries already known in it, to its further exploration, Cape Non had hitherto limited the researches of the Portuguese, and had been regarded as an impassable barrier. In the year 1412, however, ships sent out for discovery doubled this formidable promontory, and reached Cape Bojador, a hundred and sixty miles to the southward, which became in its turn the boundary of Portuguese navigation; and it continued to be so for upwards of twenty years. Under the coasting system, which still continued to be practised, it was not likely that the obstacles presented by its rocky cliffs, which stretch a considerable way into the Atlantic, would soon have been overcome. But a sudden squall of wind having driven out to sea the vessel next dispatched, this event fortunately led to the discovery of Porto Santo; whence in a little time Madeira was discovered, being first mistaken for a small black cloud in the horizon; and at length, when the Portuguese by their voyages thither had gradually become accustomed to a bolder navigation, Cape Bojador was doubled. Thus, by repeated efforts, the Portuguese navigators gradually approached the northern boundary of the torrid zone. Here their progress was for some time arrested, not by any physical difficulties, but in consequence of the influence which the opinion of the ancient mathematicians and geographers, whom they had hitherto followed as their guides, that excessive heat rendered the middle regions of the earth uninhabitable, had upon their minds. Experience, however, at length enabled them to triumph over ignorance and prejudice. A powerful fleet, fitted out in 1484, after discovering the kingdoms of Benin and Congo, advanced above fifteen hundred miles beyond the equator. Their intercourse with the natives enabled them to obtain information concerning those parts of the country which they had not visited. Not only had they detected the error of the ancients in reference to the torrid zone, but they found also that the direction of the coast was very different from what the description given by Ptolemy had led them to expect. They saw reason to conclude that the continent gradually became narrower as they proceeded southward; so that there was room to believe that the ancient accounts respecting the circumnavigation of Africa were really founded in truth. New and more extensive prospects were thus opened to them; and the finding of a passage to India by sailing round the southern extremity of Africa became a favourite project. In the year 1488 the lofty promontory which terminates that continent was descried by Bartholomew Diaz; but it was not until about ten years after that it was doubled, and the coast of Malabar reached, by Vasco de Gama.

Meanwhile, the Cape de Verd Islands, which are said to have been known to the ancients, but afterwards lost sight of, had been discovered in 1446; and soon after the Azores Isles. When we consider the distances at which these two groups of islands lie from the land, the former being upwards of 300 miles from the coast of Africa, and the latter distant 900 miles from any continent, it may be concluded that the Portuguese, when they entered so boldly into the open seas, had made no inconsiderable progress in the art of navigation.

But brilliant as is the lustre which these discoveries shed around the Portuguese name, their glory would have been still more dazzling had they seconded the profound views of Columbus, which led him to the discovery of the New World. That illustrious man and skilful navigator, by revolving in his mind the principles on which the Portuguese had founded their schemes of discovery, and carried them into execution, was led to conceive that he could improve on their plan, and accomplish discoveries which they had hitherto attempted in vain. From the time that they had doubled Cape Verd, the great object at which the Portuguese aimed was to find a passage by sea to the East Indies. The direction in which their efforts were made implied necessarily a long and hazardous voyage, should they even be successful in accomplishing their design. But as the Atlantic Ocean stretched westward to an unknown distance, was it not possible that it might reach the shores of those very countries to which it was thought so desirable to find a naval route? This supposition was perfectly consistent with the known globular figure of the earth; and it was evident, on the same principle, that the further India stretched to the east, the nearer it must approach to the western shores of Europe and Africa. Such was the idea suggested to the mind of Columbus, by the knowledge which he possessed of navigation and geography, both in theory and practice. While he found his views confirmed by a careful comparison of the observations of modern pilots with the hints and conjectures of ancient authors, he became thoroughly convinced that the navigator who should have the boldness to cross the Atlantic Ocean, would have his toils rewarded by the most important discoveries.

These ideas had presented themselves to the mind of Columbus as early as the year 1474; but it was not until the year 1492, after several years of fruitless solicitation, and of discouragements and disappointments of the most vexatious kind, that he obtained the patronage of Ferdinand and Isabella, who then governed the united kingdoms of Castile and Arragon, and was by them put in possession of the means of carrying his schemes of discovery into execution. With no more suitable an armament for his great enterprise than three small vessels, having ninety men, mostly sailors, on board, and victualled for twelve months, he sailed from the port of Palos in Andalusia on the third day of August, and steered for the Canaries. Taking then his departure from Gomera, one of the most westerly of these islands, he stretched into unknown seas; and holding his course due west, reached Guanahani, one of the Bahama Islands, on the 12th day of October. After employing some time in making further discoveries, he returned to Spain to announce the success of his undertaking, the fame of which soon spread over Europe, and excited general attention. It was no easy matter to determine what relation the newly-discovered countries bore to the regions formerly known. Columbus's own views on the subject were in strict conformity with the idea which had taken so firm a hold of his mind, namely, that India might be reached by sailing towards the west. He imagined that the islands he had visited were some of those which were said to lie contiguous to the remote shores of Asia. In this opinion he was confirmed by the coincidence which he thought he could trace between certain names given to places by the natives, and the appellations known to belong to countries situated in India. He thought he could recognise, in the answer given to his inquiries after the situation of the mines which yielded gold, the name *Cipango*, by which Marco Polo and other travellers in the East designated the island Japan. Ignorant of their language, and unaccustomed to their pronunciation, he even supposed that they spoke of the great khan; and hence concluded that the kingdom of Cathay or China, described by Marco Polo, was not far off. The same erroneous opinion was still further riveted in his mind, by what he supposed an identity between the animal and vegetable productions of the East Indies and those of the countries which he had discovered.

His second voyage led to the discovery of several more of the group of islands now called the West Indies, a name given them in conformity with the original notions of the discoverer. It was on his third voyage that he discovered the vast continent of America. Having unexpectedly found the island of Trinidad, with the neighbouring land, he encountered, before he was aware of danger, the adverse currents and tumultuous waves occasioned by the resistance which the waters of the Orinoco oppose to the tides in the ocean. His attention was thus forcibly called to the immense body of water which is here poured into the Atlantic. This he was convinced was vastly too great to be supplied by any island; and hence he concluded that he had now reached the continent which he had sought through so many dangers.

The tenacity with which an ingenious and enterprising mind adheres to a scheme which it has once proposed to itself as an object of pursuit, was strikingly evinced by Columbus, whose thoughts still dwelt with eagerness on his original and favourite plan of opening a new passage to India. It was not enough that he had astonished mankind by finding a new continent; he conceived the idea that beyond it there might lie a sea extending to the coasts of Asia, and that by diligent search some strait might be found which would conduct him into this sea, or some narrow neck of land, by crossing which it might be reached. To determine this important point, though hitherto his services had met with the most unworthy returns, though years crept upon him, though worn out by fatigue and broken with infirmities, he still undertook with alacrity another voyage. By a lucky conjecture he directed his efforts towards the east of the Gulf of Darien; but he searched in vain for a strait; and though he frequently went on shore and advanced into the country, he never penetrated so far as to enable him to descry the great Southern Ocean.

After the first steps had been taken, the progress of discovery over the globe was astonishingly rapid. No expense or danger deterred even private adventurers from fitting out fleets, crossing oceans, and encountering the rage of savage nations in the most distant parts of the earth. Before Columbus had reached the continent at the mouth of the Orinoco, Newfoundland had been discovered by Cabot, a Venetian by descent, but sailing under the auspices of England. He had also coasted along the present territory of the United States, perhaps as far as Virginia. In the next two or three years, the Cortereals, a daring family of Portuguese navigators, began the long and unavailing search of a passage round the northern extremity of America. They sailed along the coast of Labrador, and entered the spacious inlet of Hudson's Bay. Two of them unfortunately perished in this enterprise. In the year 1501 Alvarez Cabral, a Portuguese navigator, destined for India, having stood out to sea in order to avoid the variable breezes and frequent calms which he was sure to meet with on the African coast, to his surprise, came upon the shores of an unknown country, the coast of Brazil, which he claimed for Portugal. Amerigo Vespucci, a Florentine gentleman, who had already sailed along a great part of Terra Firma and Guyana, now made two extensive voyages along the Brazilian coast. Soon after his return he drew up and transmitted to one of his countrymen an account of his adventures and discoveries, in which he insinuated that to him belonged the honour of having first discovered the continent in the New World. His performance, which was the first description published of the newly-discovered countries, circulated rapidly, was read with admiration, and became the means of procuring for its author the high honour of giving his name to the whole continent. Not many years elapsed before the conjecture of Columbus respecting the existence of an ocean beyond the continent which he had discovered was found to be true; and his favourite project of opening a passage to India by steering westward was actually accomplished. By crossing the narrow isthmus of Panama, Nuñez Balboa reached the Pacific Ocean in the year 1513; and in 1521 Magellan discovered and sailed through the famous straits which bear his name. After twenty days occupied in navigating this dangerous channel, he beheld spread out before him the boundless expanse of the great Southern Ocean. Directing his course to the north-west, he continued his voyage for nearly four months without discovering land. From want of provisions, and from sickness, he and his crew suffered dreadful distress. But when about to sink under their sufferings, they fell in with the Ladrone Islands, where they found refreshments in abundance. From these isles he proceeded on his voyage, and was not long of discovering the Philippines. Here, in an unfortunate quarrel with the natives, he was slain, with several of his principal officers. But his surviving companions, pursuing their voyage, and returning to Europe by the Cape of Good Hope, solved the great problem of the circumnavigation of the earth.

After the discovery of the Pacific Ocean by Balboa, the investigation of the western coasts of America went speedily forward. Expeditions were soon sent out both northward and southward; so that nearly a full view was obtained of the immense range of coast which the American continent presents to the Pacific Ocean, and at the same time of its great interior breadth.

On the other hand, discovery in the eastern world was no less rapid. Within twenty years from the time that Gama reached India by the way of the Cape of Good Hope, all the coasts of Hindustan, those of Eastern Africa, of Arabia, and Persia, had been explored. Navigators had penetrated to Malacca and the Spice Islands. They had learned the existence of Siam and Pegu; and it was only the characteristic jealousy of the rulers of the Celestial Empire that prevented them from entering the ports of China.

The scientific geographer had now abundance of materials to arrange and digest into one systematic whole. He was now called upon to give such a delineation of the earth's surface, as should connect together the ranges of eastern and western discovery, and should exhibit the true outline and relative positions of countries, as these had been demonstrated by the astronomer and navigator. The ancient system of geography, to which the Arabs seem closely to have adhered, was founded on the idea of the whole earth being surrounded by an ocean as by a great zone. This the Arabians characterized as the "Sea of Darkness," an appellation most usually given to the Atlantic; while the northern sea of Europe and Asia, as inspiring still more gloomy and mysterious ideas, was styled the "Sea of Pitchy Darkness." Such notions could not now keep possession of the human mind, though it was only by degrees that mankind could be expected to be enlightened by doctrines which were not only new, but seemed likewise to be contradicted by the evidence of sense. The fundamental principles of a systematic arrangement had, as we have already seen, been known from the time of Hipparchus, and had been reduced to practice by Ptolemy. But the want of astronomical observations, or even of accurate surveys, which navigators seldom furnished, and for which science had not indeed yet provided suitable instruments, placed it still beyond the resources of modern geography to give any thing like a just representation of the two hemispheres. The Venetian geographers were the first who attempted a systematic arrangement of the immense regions recently discovered, adjusting them to each other, and to the mass of information previously possessed. But a series of Venetian maps, preserved in the king's library, show how much their skill was counteracted by the difficulties with which they had to contend. Instead of exhibiting the vast ocean which separates the east coast of Asia from the west coast of America, the two continents are represented either as meeting, or as separated only by a narrow strait. The voyage of Magellan across the Southern Ocean had not shown with sufficient distinctness the presentation of the opposite coasts, to enable the geographers of the time to avoid this error. When maps of different dates are compared, we find, as we descend towards modern times, a gradual progress towards accuracy in the representations given of the earth's surface. This is what might be expected; for all maps should be considered as unfinished works, in which there will always be something to be corrected, or something new to be inserted.

At the period of the revival of letters in Europe, the latitudes and longitudes, as given by Ptolemy, were universally received with implicit confidence. When checked, however, by actual observation, they were found to differ materially from the truth. The latitudes in many instances were found very erroneous; that of Byzantium, for example, exceeded the truth by two degrees. As nearly the same excess was found to exist in some other cases, many geographers, unwilling to renounce the authority of Ptolemy, concluded that this difference had arisen from a change having taken place in the position of the earth's axis, in consequence of which the latitudes of all the places in Europe were increased. The progress of observation showed that this opinion was untenable, and that before geography could rest on a sure basis, a general revision of ancient graduation was indispensably necessary. The only observations employed by the ancients for determining longitudes were those of the eclipses of the moon; but it was found that the results derived from this source could not be depended on. In the year 1610, Galileo, having discovered three of Jupiter's satellites, pointed out the use which might be made of their eclipses for finding longitudes. But this method, which gives the greatest degree of accuracy, was turned to little account, until 1668, when Cassini published his tables of the revolutions and eclipses of these satellites. Three years afterwards, by means of simultaneous observations made by him and Picard at Paris, and in the observatories of Tycho Brahe at Copenhagen, the difference of longitude of these two important points, which had been long a matter of dispute, was finally determined. Since that time, other accurate methods of finding the longitude have been discovered; and the instruments employed in observation have been brought to a high degree of perfection. The refinements and improvements of modern science have been brought to bear upon the great problem of determining the figure of the earth, which, though nearly, is not exactly spherical. (See FIGURE OF THE EARTH.) The labours of scientific men to obtain accurate results on this subject have contributed much to the improvement of geography. The expeditions sent out under Maupertuis to the arctic circle, and under Condamine to the equator, afforded an opportunity of making various observations of latitude and longitude in regions of which no delineation resting upon proper data had hitherto been given. Within the last thirty years, trigonometrical surveys of France and England have been executed, which have nearly completed the delineation of these countries.

Much advantage has accrued to geographical science, in point of accuracy and precision, from the application in modern times of a sound and judicious criticism to the immense mass of materials which had been accumulating for ages. The labours of M. d'Anville, in the eighteenth century, were employed with great success in this department. He undertook the revision of the whole system on which the delineation of the world, and of the countries into which it is divided, had hitherto been made; and by unhesitatingly rejecting every particular that did not rest on positive authority, he removed many false or uncertain features, and clearly distinguished the known from the unknown parts of the globe. Major Rennell has skilfully arranged and illustrated the important materials collected respecting India. Various authors have in moern times cultivated another interesting field of inquiry, the comparison between ancient and modern geography, and the tracing of the rise and progress of early discovery. These researches were diligently pursued by Vossius, Bochart, and other learned men of the seventeenth century, and with still more success by Rennell, Vincent, and Mannert, who appear to have pushed them as far as they admit, though much darkness still rests on some parts of the inquiry. Gosselin, notwithstanding that he has applied to the subject a great extent of investigation, as well as much skill and force of criticism, has failed, on account of the peculiar views in which he indulged, to make any solid addition to the science.

The discoveries made by the Spaniards and Portuguese had greatly increased the stock of geographical information. Still much remained to be done. The desire of finding a short and convenient route to India still continued to supply a stimulus to exertion in the way of discovery. The English and Dutch made extraordinary efforts, and encountered fearful dangers and disasters, with the expectation of effecting a passage by the north-east, along the northern shores of Asia. A coast beset with the ices of the Polar Seas presented, however, obstacles too formidable to be overcome; though recent researches appear to show that no barrier of land intervenes. But there was still another quarter where an attempt might be made; and to this point the commercial nations of Europe failed not to direct their efforts. The jealousy of Spain long prevented the other European states from visiting the north-western coast of America, so that they remained ignorant of the vast breadth to which the continent spreads out as it advances towards the north. They adopted, indeed, the opinion that, like the southern extremity, the northern terminated in a point or cape. This left room to hope for a north-western passage into the Pacific Ocean, by sailing round the imaginary cape. The English took the most decided lead in the exploratory voyages to which these views gave rise. In the reign of Queen Elizabeth, Frobisher and Davis were sent out on three successive voyages, which led to the discovery of the entrance into Hudson's Bay by the former navigator, and of the entrance into Baffin's Bay by the latter. These two capacious basins were afterwards discovered by the intrepid navigators whose names they bear. In sailing round the great sea which he had discovered, Baffin mistook the great opening into Lancaster Sound for a mere gulf; a misapprehension which checked for a time any further attempts in that quarter, as navigators were led to expect success only through the channel of Hudson's Bay. In 1631, Fox explored a part of that great opening on the north of Hudson's Bay, called Sir Thomas Roe's Welcome, which seemed now to hold out almost the only hope of accomplishing the object sought. The assertion of Middleton, an officer in the service of the Hudson's Bay Company, that he had discovered the head of the Welcome to be completely enclosed, and the circumstance of two other navigators, who were sent out the following year, failing to effect any thing, produced an impression on the public mind that the passage so long sought had no existence.

The discoveries of Cook in the North Pacific Ocean, where he found the American coast stretching away in a north-westerly direction, joined to the circumstance that, when he penetrated through the strait discovered early in the last century by Behring and Tchirikof, which separates America from Asia, the coast appeared there to extend indefinitely to the north, seemed not only to confirm the conclusion that no passage into the North Pacific Ocean was here to be expected; but also that the American continent extended northward in one unbroken mass, perhaps even to the pole. The groundlessness of these views became apparent when, in the year 1771, Mr Hearne, who had been dispatched by the Hudson's Bay Company to explore the limits of the coast in this direction, sailed down the Copper-Mine River, and discovered its entrance into the sea; and again, when, in 1780, Sir Alexander Mackenzie traced also to the sea another river about twenty degrees farther to the west. Thus were there furnished strong grounds to believe that the pole was surrounded by an ocean which separated the northern coasts of Asia and America, making these two continents altogether distinct from each other; and that through this ocean lay the long-sought course which would certainly conduct the navigator who should succeed in forcing his way through the ice and storms of the polar regions, from the Atlantic into the North Pacific Ocean.

The determination of this great geographical question, so long agitated, has recently called forth the utmost efforts of the British government. In 1818 an expedition was sent out to Baffin's Bay under the command of Captain Ross, without leading to any important result, as he was led to conclude that no opening existed. Lancaster Sound had, however, forcibly attracted the attention of Lieutenant Parry, second in command; and on returning with a new expedition under his immediate command, he succeeded in penetrating through Lancaster Sound, which he found gradually to widen till it opened into the Polar Sea. He found a chain of large islands to lie parallel to the American coast; and among these he continued his navigation until the accumulation of ice in the straits and channels through which he had to pass stopped his further progress. This circumstance induced him to make his next attempt through Hudson's Bay, by the channel of the Welcome, which had as yet been but imperfectly explored. Here he succeeded in reaching a point considerably beyond that at which Middleton had represented the bay as terminating. He found at length a narrow strait communicating with the Polar Sea, but so encumbered with ice as to preclude the hope of its ever affording an open passage. He was therefore again sent out to renew his efforts in the first direction, where he had already obtained partial success. But the obstacles which he had formerly been unable to overcome still continued, and prevented him from making any material addition to his former discoveries. Whilst these skilfully-conducted voyages were in progress, Captain Franklin was sent out at the head of two successive expeditions by land, and, by actual survey, ascertained three fourths of the boundary coast; his operations terminating at a point beyond the 149th degree of west longitude. On the other hand, an expedition under Captain Beechy, sent to meet Captain Franklin on his second toilsome journey, passed the Icy Cape of Cook, and penetrated nearly as far as the 156th degree of west longitude, leaving only seven degrees, or 160 miles, between the farthest point thus reached and the utmost limit reached by Captain Franklin. The results of this investigation appeared to prove that the whole of the northern coast of America extends in a line not varying much from the parallel of the seventieth degree of latitude. But Captain Ross, in the late expedition fitted out by himself, has found a large peninsula stretching as far north as seventy-four degrees of latitude. The existence of a naval passage farther to the north, in the line of Captain Parry's first voyage, is, however, still probable.

The discovery of a new continent greatly enlarged, as we have seen, the views of mankind respecting the constitution of the globe. But imagination, no longer limited in its range by the notion of a circumambient ocean that could not be passed, soon gave rise to the belief of a southern continent, which was supposed necessary to balance the land in the northern regions of the earth. The immense body of water that was found to occupy so large a portion of the known regions of the southern hemisphere gave ample room for supposing this unknown continent to be of vast dimensions. It was imagined that it might equal in extent as well as in wealth the American continent. Nor was it considered necessary to exclude it from the map of the world till its existence should be proved. It appears in all the early maps as an immense mass of land surrounding the south pole, and presenting to the ocean one unbroken coast. The discovery of certain great insular tracts in the South Seas, which, from ignorance of their true nature, navigators might mistake for continental promontories or portions of coast, no doubt at first gave some countenance to the belief of the existence of antarctic land. But the delusion was gradually dispelled before the light afforded by further discovery. The Portuguese, in less than twenty years after their passage of the Cape of Good Hope, pushed their researches to the most remote islands in the Indian Ocean, including Java and the Moluccas. They appear also to have observed some part of the coast of New Guinea. The Spaniards during their early and adventurous career put forth strenuous exertions to explore the Southern Ocean, and several of the groups of islands scattered over its surface were discovered by their navigators. In 1607, the Dutch having wrested from the Portuguese Java and the Spice Islands, established in them the centre of their Indian dominion. A great maritime power being thus placed so near to the northern shores of the largest portion of land on the globe that is regarded as an island, it became almost impossible that New Holland could long remain unknown. It was discovered early in the seventeenth century, and was long supposed to form a part of the great southern continent. Van Diemen, the Dutch governor of India, sent out several vessels successively to explore its coasts. Hertog, Carpenter, Nuytz, and Ulaming, made very extensive observations on the northern and western shores, but found them so dreary and uninviting that no settlement was attempted. In the year 1644 the eastern coasts were visited by Tasman, who, proceeding beyond his predecessors, reached the southern extremity of Van Diemen's Land, to which he gave its name; but he failed to discover that it is a separate island. Pursuing his course eastward, he surveyed next the western coast of New Zealand, and returned home by the Friendly Islands. He thus proved that New Holland was no part of the southern continent, even should such a continent exist. Cook, by ranging along the borders of the southern pole, where he found only isles and firm fields of ice, showed that the hypothesis of an austral continent had no foundation. The eastern side of New Holland was discovered by Captain Cook in the year 1770, who by his extensive operations in that quarter left little to be done towards completing the full circuit of it. The same great navigator likewise secured glory to his country and to himself by completing the survey of the Great Pacific Ocean. Some of the interesting groups of islands scattered over its vast surface had already been made known by the previous voyages of Byron, Wallis, and Carteret. Cook fully traced the great chain of the Society Islands and the Friendly Islands. He determined also the form and relations of New Zealand, New Caledonia, and other great lands and islands in that region of the globe.

The extensive island of New Holland has recently become doubly interesting from the important relations which now subsist between it and Europe. In the year 1788 the establishment of a British colony on the east coast paved the way for a more complete survey. By the different expeditions undertaken from 1795 to 1799, chiefly under the direction of Bass and Flinders, the east coast, together with Van Diemen's Land and Bass's Strait, which separates that island from New Holland, were accurately explored. In 1801 an expedition was sent out by the British government under the command of Captain Flinders, for the purpose of surveying a large portion of the coast. These surveys were prosecuted with unremitting ardour and perseverance. At the same time that Captain Flinders was carrying on his survey, the French captain Baudin was employed on the same service, and in some parts the discoveries of these navigators intermingle. Some additional observations have more recently been made; and by these various expeditions the whole coast of New Holland and Van Diemen's Land has been accurately surveyed, the position of every point has been ascertained, and every inlet and bay has been traced to its termination.

In tracing the history of geographical discovery, it cannot fail to be observed, that while discovery by sea has been pursued with great advantage, on account of the rapidity of its progress and the extent of its range, the slower and more confined operations of the discoverer by land are no less necessary to make known the interior features and circumstances of the different countries.

The British dominion in India has led to much additional information respecting the interior of Asia; information which is, however, in many respects, only the revival of ancient knowledge. The great mountainous chain which forms the northern boundary of India has been traced and found in many places to tower to such heights as to exceed the Andes, long supposed to be the highest mountains in the world. The source of the Ganges, and that of the Indus, with the early courses of these great rivers, have been found to be situated quite differently from what had been supposed to be their position by modern geographers. The mountainous territories of Cabul and Cashmere, the high interior table-land of Thibet, and the vast sandy plains of Meckran, have all been more or less explored. Information of an authentic character has also been recently obtained respecting the formerly celebrated capitals, Bochara and Samarkand. But a wide field still remains for future research.

The continent of Africa, however, is the quarter of the globe which, more than any other, has baffled the efforts of those who would explore its interior. The vast sandy deserts, high mountains, and impenetrable forests which occur on its surface, joined with the unremitting wars carried on between the petty tribes, and the deeply-rooted antipathy of the African Mahommedans towards the Franks, have presented obstacles of the most formidable kind. The ancients, whose knowledge of the African coasts was very imperfect, except where they border on the Mediterranean and the Red Sea, were accustomed to penetrate into the inland provinces, and are said to have been acquainted with many parts of it which are now altogether unknown. At an early period of modern history reports that Prester John, the Christian prince, who had been sought for in vain in the East, was to be found in the interior of Africa, induced the Portuguese to explore Abyssinia; but the accounts which they gave of the extent of that country were greatly exaggerated. From the western coast they dispatched embassies into the interior in quest of the object of their search; and on one occasion they appear to have reached the city of Tombuctoo, and to have obtained at Benin some information concerning the great interior kingdom of Ghana. Tombuctoo has been for many centuries the grand emporium of the central trade of Africa; and on this account an eager desire has been felt in Europe, ever since the rise of discovery and commercial enterprise, to visit it and establish an intercourse with it. All attempts, however, to reach it made by European merchants and travellers have until recently been entirely baffled. Its actual condition, and even magnitude, are still involved in very considerable uncertainty. Major Laing resided there a considerable time, and made the most diligent inquiries; but the fatal catastrophe which terminated his career prevented the result from ever reaching Europe.

But the grand object connected with the interior of Africa, by which the attention of Europeans has been from the first chiefly excited, is its great central river, the Niger. The interest with which this stream has been regarded has arisen from the remarkable nature of the regions through which it flows, and still more from our ignorance, combined with the various and contradictory rumours which were so long abroad respecting its course and termination. Herodotus is the earliest author who affords any ideas applicable to this subject. He mentions an expedition into the interior of Africa, undertaken by some Nasamonian youths, who, being taken prisoners, were carried to a great city inhabited by negroes, and situated on the banks of a river which flowed from west to east. This stream he conjectures to be the remote source of the Nile; but the particulars given appear to leave little doubt that it was the Niger. A similar hypothesis was adopted by Strabo, Mela, and Pliny, identifying the waters of these two great rivers. But Ptolemy, whose residence in Alexandria afforded him ample means of information, rejects altogether the idea of any communication between them. He describes the Niger as terminated on the west by Mount Mandrus (Mandingo), and as giving rise to several extensive lakes as it proceeds in its course. His statements do not, however, involve any thing positive as to the direction in which it flows. The Saracens or Arabians are the next great source of information; for in the course of the dissensions which took place among their dynasties in Northern Africa, large bodies crossed the desert, and founded kingdoms on the eastern part of the shore of the Niger, of which the kingdom of Ghana was the most splendid. According to their testimony, the Niger flows from east to west, and discharges itself into the sea, by which they understood the Atlantic, or great circumambient ocean. With regard to its source, they generally regarded it as the same with that of the Egyptian Nile, identifying the two rivers in the early part of their course. Some were of opinion that the waters of the Niger did not reach the sea; so that they must have supposed them to be discharged into a lake. The system adopted by modern Europeans was derived from Leo Africanus, who retained the delineation of the Niger as flowing from east to west, and falling into the ocean, but instead of deriving it from the Nile, supposed it to rise from the lake of Bornou, lying deep in the interior of Africa. Following this hypothesis, all the early European navigators, when they saw the two broad estuaries of the Senegal and Gambia, concluded that one or both gave egress to the waters of the Niger. In the beginning of the seventeenth century, the French and English having each formed a settlement, the one on the Senegal and the other on the Gambia, were induced by the hope of gain to seek a route up these rivers to the city of Tombuctoo; and in this enterprise they proved the falsity of the opinion which had been so long held. The streams were traced so near to their source as to become little more than rivulets; whilst the explorers were still far from the great central emporium of Africa, and from the great plain through which the Niger was understood to flow. This result led the two great French geographers Delisle and D'Anville to construct maps in which the Niger, after the lapse of so many ages, was again represented as flowing to the eastward. Instead of a single stream pursuing a course across the whole breadth of Africa, and falling into the Atlantic, D'Anville distinguished three rivers; the Senegal flowing westward, the Niger flowing eastward into a lake in Wangara, and another river still farther east, and flowing in the opposite direction. The data on which this scheme rests were never fully made public.

Still new doubt was thrown around this subject by the reports collected by Mr Lucas, who travelled under the auspices of the African Association, and who was assured at Tripoli, by a native merchant, that the river flowed with rapidity in a westerly direction. The time, however, at last arrived when these conflicting opinions were to be silenced, and new light thrown on the subject, by the labours of our illustrious modern traveller Mr Park. In his first expedition, on reaching Sego, he beheld "the long-sought majestic Niger, glittering in the morning sun, as broad as the Thames at Windsor, and flowing slowly to the eastward," and directing its course into the depths of interior Africa. Here, then, was a new point from which theory and conjecture might start in endeavouring to ascertain the termination of the Niger. By the persevering exertions of the British government, an expedition has, however, at length actually made its way into the unknown interior of Africa, and has finally led to the solution of the grand problem which had so long puzzled geographers, as well as exercised their ingenuity. Without entering further into details, it will be sufficient to observe, that instead of only one river being found flowing through the great African plain in one direction, there were several rivers discovered flowing in different directions; all of which, it appears, have been considered at different times, and under different circumstances, the Niger. Hence had arisen the various statements which for ages involved the subject in such deep mystery. The great central stream of Africa has now been very completely traced, whilst much light has been obtained respecting the regions through which it flows. It was reserved for Lander finally to trace the course of the Niger to the Gulf of Benin, where its waters are discharged through a succession of estuaries, extending along the coast a space of about 300 miles. Thus, by means of this river and its numerous tributaries, the prospect is now opened to British commerce of being able to penetrate into the most inland and finest regions of the African continent.

In all parts of the habitable globe the spirit of research, which has already done so much, is still active; nor is it directed only to the determining of the outlines of continents and countries, or to the marking of the leading features of mountains, rivers, and cities, with their relative positions and distances. These are regarded by the geographical inquirer merely as affording a proper basis on which to rest the description of the earth considered as the habitation of man, and as affording him amply the means of improvement and happiness. The picture can be completed only by the continued labours of the scientific observer, who makes the earth, with its various productions, whether natural or artificial, the treasures hid in its bosom, the animals found upon its surface, and, above all, the human beings who people its different regions (and these in all their mutual bearings and relations), the objects of attentive examination and study.

II.—MATHEMATICAL GEOGRAPHY.

CHAP. I.—PRINCIPLES AND DEFINITIONS: OF THE TERRESTRIAL SPHERE.

We have already stated that mathematical geography treats of the figure, magnitude, and motion of the earth; its relations to the other bodies of the system to which it belongs; the relative positions of places on its surface and the methods of delineating the whole or any part of its surface. Several of these topics belong as much to astronomy as to geography; for the former science regards the earth, on the one hand, as the grand observatory whence the phenomena of the heavens are contemplated by man; and, on the other hand, as itself constituting a portion of the planetary system, the laws of which it is the object of the astronomer to investigate and explain. It is only, indeed, by celestial observation that the position of a point on the surface of the earth can be accurately determined; so that the first principles of geographical science must necessarily be drawn from astronomy.

We take for granted, then, the doctrine of the celestial sphere; the globular form, the magnitude, and motion of the earth, with the phenomena arising out of and depending upon its motion. These points are fully discussed in the article Astronomy, part ii. It will be necessary, however, for the sake of distinctness, to state briefly such of the results derived from the reasoning there employed as belong specially to the subject of this article.

The doctrine of the earth's rotundity is that with which the student of geography must first make his mind familiar. To the eye the earth appears a circular plane, at the centre of which the spectator imagines himself placed; whilst the heavens, spread over his head like a magnificent canopy, seem to meet the earth all round in a circle which bounds the view. The space comprehended within this circle is found to present often a very irregular surface, rising into mountains, or sinking into cavities, so as apparently to exclude the idea of its bearing any resemblance to a portion of a globe or sphere. This is, however, nearly its true figure. Were we placed at such a distance from the earth that the eye would be able to take in at one glance the vast mass in its full dimensions, it would present the appearance of a circular disk, of greater or less diameter according to our distance. If viewed on all sides, its circular form would remain unchanged; a property characteristic of no other body but a globe or sphere. The highest mountains would be found to bear so little proportion to the whole bulk, as to cause no perceptible deviation from the globular form; and the same thing may be said of the difference which exists between the polar and equatorial diameters, though that quantity amounts to about twenty-eight miles.

The portion of the earth, then, seen from any point above its surface, is to be regarded as the segment of a sphere, which increases in extent according as the eye is more elevated. Knowing the semidiameter of the earth, and the height of the eye above the surface, it is easy to find the diameter of the circle which bounds our view on the earth; supposing, as is the case at sea, that no object should intervene to obstruct our vision. Thus, let AB (Plate CCLIX. fig. 1) be the height of a mountain on the earth's surface. From A draw the line AD, a tangent to the surface in any direction; D will be the most distant point seen by a spectator whose eye is placed at A, the summit of the mountain. If the line AD be supposed to be carried round the point A, while it at the same time continues to be a tangent to the surface, until, having passed through every possible position, it returns to that from which it set out, the point D will trace the circumference of the circle which bounds the terrestrial view, and of which the radius will not differ much from AD. Now AD being a tangent to the arch BD, we have $AD^2 = (2BC + AB) \times AB = 2BC \times AB$ nearly, since AB must always be very small compared with 2BC, the diameter of the earth. Assuming the diameter equal to 7912 English miles, we have $AD^2 = 7912 \times AB$; or, if AB is expressed in feet, $AD^2 = \frac{7912}{5280} \times AB$. Hence, extracting the square root of the numerical part, we obtain

$$AD = 1{\cdot}224126\sqrt{AB}.$$

The result obtained from this formula will deviate from the truth in consequence of the effect of refraction. The error arising from this cause is found to vary from $\frac{1}{4}$ to $\frac{1}{25}$ of the whole distance. At a medium, refraction may be considered as increasing the distance by about $\frac{1}{14}$, or ·0714 of the whole. Applying this correction to the above formula, it becomes

$$AD = 1{\cdot}3115\sqrt{AB}.$$

For example, if the Peak of Teneriffe is 12,358 English feet in height, then $AD = 1{\cdot}3115\sqrt{12358} = 145{\cdot}8$ miles is the radius of the circle which bounds the view from that elevation.

The circle bounding terrestrial vision, which we have now been considering, does not, except when the eye is close to the surface of the earth, coincide with the sensible horizon as determined by a plane passing through the eye along the line HO, and perpendicular to the vertical line CZ. (See Astronomy, p. 754.) The angle contained between the visual ray AD and the horizontal plane, is called the *dip* of the horizon. For ordinary purposes, however, it is sufficiently accurate to say that the *sensible horizon* is the circle which bounds the view, where the heavens and the earth appear to meet. To this circle the *rational horizon* is parallel, being determined by a plane passing through the centre of the earth perpendicular to the vertical line CZ, and continued in every direction to the sphere of the heavens. Let NESQ (Plate CCLIX. fig. 2) be the terrestrial sphere, of which C is the centre; HO is the rational horizon of the point M.

The rotatory motion of the earth determines the position of the line NS (Plate CCLIX. fig. 2), on which it revolves, and which is called its *axis*. The two points N, S, in which the axis meets the surface, are called the *poles of the earth*. The circle EQ upon the earth, the plane of which passes through C the centre, and is perpendicular to NS the axis, is called the *equator* or *equinoctial line*. This circle is equidistant from the poles of rotation, and its plane coincides with the plane of the celestial equator. The rational horizon and equator being two great circles of the terrestrial sphere, that is, the plane of each passing through the centre, they are mutually bisected. This is a property which belongs to all great circles. Any great circle NPS passing through the two poles is called a *meridian*. Any given point P may have a meridian passing through it; and the plane of that circle will coincide with the plane of the celestial meridian which passes through the zenith of that point. Every meridian cuts the equator at right angles.

The horizon HO corresponding to any point M upon the globe, is divided into four equal parts by the equator and the meridian passing through that point. The points of division are called the four *cardinal points*. Those through which the meridian passes are called the *north* and *south* points of the horizon. Those points, again, through which the equator passes are called the *east* and *west* points.

The earth is divided by the horizon into two hemispheres, called the *upper*, and *lower* or *under hemispheres*; by the equator it is divided into the *northern* and *southern hemispheres*; and by the meridian, into the *eastern* and *western hemispheres*.

The position of any point P on the surface of the earth is determined by referring it to the co-ordinate circles, the equator and meridian. The distance PA of the place P from the equator, measured in degrees and parts of a degree on the meridian passing through the place, is called its *latitude*, which is said to be north or south, according as the place is situated in the northern or southern hemisphere. The arch EA of the equator, intercepted between the meridian passing through the place P and some particular meridian NMS, called the *first meridian*, as being that fixed on from which the reckoning is to commence, is called the *longitude* of the place in question; and is east or west, according as the place is situated in the eastern or western hemisphere in reference to the first meridian. The difference of longitude between two places

Mathematical Geography.

the arch of the equator intercepted between their meri-ians; and is found by subtracting or adding the longitudes, cording as the places are on the same or on opposite sides the first meridian. The ancients assumed for their first eridian that of the Fortunate Islands, which they conceivl to be the western limit of the habitable world. In latr times, the meridian passing through Ferro, one of the anary Islands, and nearly coinciding with that of the anents, was used as the first meridian by the geographers many countries. But in modern systems of geography e first meridian is that which passes through the capil of that country, or through an observatory, if there is e in or near the capital, from which the position of her meridians is determined. By British geographers e meridian of the observatory at Greenwich is reckoned e first meridian. It is usual to call the semicircle NPS, ssing through the two poles and a given place, the melian of that place; and the other semicircle NRS passing rough the opposite point on the globe, the opposite melian. All places lying under the same meridian have e same longitude, and at all of them noon or any other ur occurs at the same instant of absolute time. With gard to places that lie towards the east and west of the eridians of each other, this is not the case. The sun in s apparent diurnal revolution moves over fifteen degrees an hour; so that at a place in fifteen degrees east longude, noon occurs an hour earlier than at places under e first meridian, and at a place in fifteen degrees west gitude, an hour later; and each fifteen degrees by ich the longitude east or west is increased, makes an ditional hour of difference in the time at which noon curs. Hence longitude, and difference of longitude, y be estimated in time, allowing fifteen degrees to an ur, or one degree to four minutes.

If a small circle MPK, or *mpk*, be drawn parallel to the equator at any distance from it, all the places through which that small circle passes will have the same latitude. Such small circles are accordingly called *parallels of latitude.* The difference of latitude between two places is the arch of the meridian intercepted between their parallels of latitude, and is found by subtracting or adding the latitudes, according as the places lie on the same or on opposite sides of the equator.

On the hypothesis of the earth being a perfect sphere, the degree of latitude must be assumed as everywhere of the same length. Actual observation shows that this is not exactly the case, but that the length of the degree increases slightly as we proceed from the equator towards either pole (see FIGURE OF THE EARTH), so as to indicate a flattening of the surface in the latter regions, or that the earth is of a spheroidal figure. This, however, we do not at present take into view. With regard to the degree of longitude, it is at the equator of the same length with the degree of latitude. But on both sides of the equator it decreases gradually on account of the meridians approaching each other until they intersect at the poles. At the equator a degree of longitude is the 360th part of the circumference of a great circle of the terrestrial sphere; at every point to the north or south of the equator it is the 360th part of the circumference of a small circle, of which the radius is equal to the cosine of the latitude. Now, since similar portions of the circumferences of circles are to one another as their radii, if we put L for the length of the degree of longitude at the equator, and L′ for its length in a latitude denoted by l, we have rad. : cos. l : : L : L′. Hence, radius being unity, we obtain

$$L' = L \times \cos. l.$$

From this formula the following table is calculated; the length of the degree of longitude at the equator being assumed equal to 69·06 English miles.

ble showing the Length of a Degree of Longitude for every Degree of Latitude, in Geographical and in English Miles.

Mathematical Geography.

If a great circle B*d* be supposed to be drawn on the terrestrial sphere, cutting the equator obliquely at an angle of about twenty-three and a half degrees, this circle will mark out the course of the sun through the year, and is called the *ecliptic.* It corresponds with the celestial ecliptic, and is divided in the same manner into signs and degrees. The parallel of latitude which passes through the point of the ecliptic in which the sun is placed on any particular day, shows to what points of the earth's surface the sun is vertical on that day. The two parallels BLD, *bld,* which touch the ecliptic at the points where it recedes farthest from the equator to the north and south, are called the *tropics;* the one, BLD, the northern tropic, or the tropic of cancer; and the other, *bld,* the southern tropic, or the tropic of capricorn; because they touch the ecliptic in the first points of these signs. These circles lie in the planes of the corresponding circles in the celestial sphere.

Of the two poles, that which lies in the northern hemisphere is called the *north* or *arctic pole;* and the opposite, lying in the southern hemisphere, is called the *south* or *antarctic pole.* The two parallels of latitude FG, *fg,* which encircle these poles respectively at an angular distance equal to the obliquity of the ecliptic, are called the *polar circles,* the one the north or arctic, and the other the south or antarctic.

Suppose a great circle to be drawn on the terrestrial sphere everywhere equally distant from that point on the surface to which the sun is vertical at any given time; this circle is called the *circle of illumination,* because it separates the enlightened from the dark hemisphere of the earth. It is upon the position of the circle of illumination that the equal or unequal lengths of the days and nights throughout the year depend over the face of the earth. At every season of the year this circle bisects the equator, so that under the equator the days and nights are always equal. When the sun is over either of the equinoctial points E, Q (Plate CCLIX. fig. 6), the circle of illumination bisects not only the equator, but likewise all the parallels to the equator, in consequence of cutting them at right angles; and hence, as the parallel of latitude passing through any point on the earth's surface may be regarded as the path along which that point is carried by the diurnal motion of the earth, at that season of the year the days and nights are equal over all the earth. When the sun is over any other point of the ecliptic, the parallels of latitude are cut obliquely by the circle of illumination, so that they are divided by it into two unequal parts (Plate CCLIX. fig. 7, 8); and hence the days and nights are unequal all over the earth, except at the equator. If the sun is in north declination (fig. 7) at all places to the north of the equator, the days are longer than the nights; but at all places to the south of the equator the nights are longer than the days; because with regard to places to the north, the larger portion of the parallel of latitude lies within the enlightened hemisphere, while with regard to places to the south the larger portion lies within the dark hemisphere. The reverse has place when the sun is in south declination (fig. 8). When the sun is over the northern tropic BD (fig. 7), or over the southern tropic *bd* (fig. 8), the day is then the longest or shortest of the year; and the adjacent polar circle is wholly in the light, and the opposite one wholly in darkness. Thus, within the arctic and antarctic circles the inhabitants have their light and darkness extended to a great length; the sun sometimes skirting round a little above the horizon for many days together, and at another season never rising above the horizon at all, but making continual night for a considerable length of time.

Such are the circles supposed to be drawn on the terrestrial sphere. Though these circles are altogether imaginary, and have really nothing corresponding to them on the earth's surface, yet as the positions of the corresponding circles in the heavens can be accurately determined by observation on the celestial bodies, they become actually as effective for fixing the relative positions of places on the globe of the earth, and for other purposes of geography, as if that globe were reduced to such a magnitude as to admit of its being grasped by the hand of man, and surveyed by a single glance of his eye.

The height NO of the pole (Plate CCLIX. fig. 2) adjacent to any place M above HO the horizon of that place, is equal to the latitude of the place; for the arches MO and EN are equal, each being a quadrant; and taking away from each the common arch MN, the remaining arch NO, the elevation of the pole N, is equal to the remaining arch ME, the latitude of the place M.

Hence there are, with regard to the horizon, three positions of the terrestrial sphere, as there are of the celestial, depending on the latitude of the place. If an observer were placed on the pole, the latitude being 90°, his horizon would coincide with the equator, and all the parallels of latitude would be parallel to the horizon. This is the parallel position of the sphere, which is represented in Plate CCLIX. fig. 3. Again, if an observer were placed on any point of the equator, the latitude being 0, the poles of the earth must be in the horizon; and from the properties of the sphere, the equator, and all the small circles parallel to the equator, must be at right angles to the horizon. This is the right position of the sphere which is represented in fig. 4. With regard to an observer placed at any point between the equator and either pole, the axis of the earth lies obliquely to the plain of his horizon, which is therefore cut obliquely by the equator and all the small circles parallel to the equator: this is the oblique position of the sphere, and is that represented in fig. 2.

The method of determining the latitude of a place, and the difference of longitude between two points on the earth's surface, is given in the article ASTRONOMY, part iv. chap. i. prob. ix. and x. The latitudes and longitudes of two points on the surface of the earth being given, the angular distance may be found; and hence the length of a degree on the earth's surface being known, the distance between the points may be expressed in miles. Thus, let A and B be two points on the earth's surface (Plate CCLIX. fig. 5); let P be the adjacent pole, and PA, PB the meridians passing through A and B: then PA and PB will be the complements of the latitudes, and therefore given; and the spherical angle APB will be the difference of the longitudes, and therefore also given. In the spherical triangle PAB, the base AB of which is the distance required, we have therefore two sides and the included angle, so that the base AB can be found. Put D and D′ for the complements of the given latitudes, and P for the difference of the given longitudes; then, by spherical trigonometry, we have

$$\text{Cos. AB} = \text{cos. D cos. D}' + \text{sin. D sin. D}' \text{cos. P.}$$

By assuming $\tan.\varphi = \tan.\text{D}\cos.\text{P}$, this formula may be reduced to the more convenient form

$$\text{Cos. AB} = \frac{\text{cos. D cos.}(\text{D}' - \varphi)}{\cos.\varphi}.$$

From the above expression the number of degrees and parts of a degree contained in the arch intercepted between the points A and B are to be found; and allowing for each degree 69·06 English miles, the distance will be obtained, expressed in English miles, which will necessarily differ a little from the truth, in consequence of the earth not being truly spherical. To determine the distance between two points on the earth's surface with precision, requires the application of some of the most refined improvements in modern mathematics. See FIGURE OF THE EARTH.

As an example of the above formula, let it be required to find the distance between Edinburgh and Constantinople.

Colat. of Edinburgh ……$34° \ 3' = D$: its long. $3° \ 12'$ W.
Colat. of Constantinople $48° \ 59' = D'$: its long. $28° \ 55'$ E.
Difference of longitude…… $= 32° \ 7' = P$.

$$\text{Tan. } D = \text{tan. } 34° \ 3' = 9{\cdot}829805$$
$$\text{Cos. } P = \text{cos. } 32° \ 7' = \underline{9{\cdot}927867}$$
$$\text{Tan. } \varphi, \ 29° \ 47' \ldots\ldots\ldots\ldots 9{\cdot}757672$$
$$D' = \underline{48° \ 59'}$$
$$D' - \varphi = 19° \ 12' \ldots\ldots\ldots\ldots \text{Its cosine} = 9{\cdot}975145$$
$$\text{Cos. } D = 9{\cdot}918318$$
$$\text{Arith. compl. cosine } \varphi = \underline{0{\cdot}061525}$$
$$\text{Cos. } AB, \ 25° \ 38' \ldots = 9{\cdot}954988.$$

Hence the arch of a great circle of the sphere intercepted between Edinburgh and Constantinople is 25° 38′, or 1770 English miles nearly.

Each of the four quadrants into which the horizon is divided by the equator and the meridian is supposed to be divided into eight equal parts; so that the whole circumference is divided into thirty-two equal parts, which are called *points of the compass;* and to each point of division a name is given indicating its position with regard to the four cardinal points.

The position of one place with regard to another, as estimated by the points of the compass, is called the *bearing* of the former from the latter. Thus, when a place is said to bear N.E. (north-east), N.N.E. (north-north-east), &c. the meaning is, that it lies in the direction of those points in the horizon from the present position of the observer. If a series of points be assumed on the earth's surface, so situated that all of them, when taken in regular succession, lie towards any the same point of the compass, except either of the four cardinal points, the assumed points lie, not in the circumference of a circle of the sphere, but in a sort of spiral line, the characteristic property of which is, that it cuts all the meridians at the same angle. This line is called a *rhumb line;* and, whilst it continually approaches the pole, it can never arrive at it, except after an infinite number of revolutions. In passing, therefore, from one point of the surface of the globe to another, by pursuing the direction in which the latter lies from the former, we do not take the shortest way, which is an arch of a great circle, but move over a portion of a rhumb line, passing through the two points. This is the line described by a ship, whilst her course is continually directed towards one and the same point of the compass.

CHAP. II.—OF THE SURFACE OF THE EARTH, AND ITS GENERAL DIVISIONS: DEFINITIONS.

The surface of the earth contains about 196,663,400 square miles. By much the larger portion of this space is water, which is, indeed, more than twice the extent of the land. The surface of the land is exceedingly diversified, almost everywhere rising into hills and mountains, or sinking into valleys, and sometimes stretching out into plains of great extent. Amongst the most extensive plains are the sandy deserts of Arabia and Africa, the internal part of European Russia, and a tract of considerable extent in Prussian Poland But the most remarkable extent of level ground is the vast table-plain of Thibet in Asia, which is the most elevated tract of level ground on the globe. The principal mountain ridges are the Alps and Pyrenees in Europe, the Altai and Himalaya Mountains in Asia, the mountains of Atlas in Africa, and the Andes or Cordilleras in South America. The greatest concavities of the globe are those which are occupied by the waters of the ocean; and of these by far the largest forms the bed of the Pacific Ocean, which, stretching from the eastern shores of Asia and of New Holland to the western coast of America, covers nearly half the globe. The concavity next in extent is that which forms the bed of the Atlantic Ocean, extending between the new and the old worlds; and a third concavity is occupied by the Indian Ocean. The Arctic and Antarctic Oceans fill up the remaining concavities.

Smaller collections of water which communicate freely with the oceans are called *seas* (Plate CCLIX. fig. 9, 1); and of these, the principal are the Mediterranean, the Baltic, the Euxine or Black Sea, and the White Sea. Seas sometimes take their names from the countries near which they flow; as the Irish Sea, the German Ocean. Some large collections of water, though they have no immediate connection with the great body of waters, being on all sides surrounded by land, are yet called seas; as the Caspian Sea.

A part of the sea running up into the land, so as to form a large hollow, is called a *bay* or *gulf* (fig. 9, 2), as the Bay of Biscay, the Gulf of Mexico; but if the hollow be small, it is called a *creek*, a *road*, a *haven.*

When two large bodies of water communicate by a narrow pass between two adjacent lands, the pass is called a *strait* or *straits* (fig. 9, 3), as the Straits of Gibraltar, the Straits of Dover, the Straits of Babelmandel. A channel is a wider kind of strait. The water usually flows through a strait with considerable force and velocity, forming what is called a *current;* and frequently this current, as in the case of the Straits of Gibraltar, flows continually in the same direction.

A body of fresh water entirely surrounded by land is called a *lake* (fig. 9, 4), as the Lake of Geneva, Lake Champlain.

A considerable stream of water rising inland, and draining a portion of country more or less extensive, discharging its waters into the sea, is called a *river.* A smaller stream of the same kind is called a *rivulet*, or *brook* (fig. 9, 5).

The great extent of land which forms the rest of the surface of the globe is divided into innumerable portions; two of vast extent, but the rest of comparatively small dimensions. The portions of the land which are of great extent are called *continents*, the one the eastern continent, or the old world, comprehending Europe, Asia, and Africa; the other the western continent, or new world, comprehending North and South America. New Holland is a third portion of land, however, which has by some been also reckoned a continent on account of its great extent.

A portion of land entirely surrounded by water is called an *island* (fig. 9, *a*), as Britain, Ireland, Jamaica, Madagascar. According to the strict meaning of this definition, the largest portions of land on the surface of the globe may be said to be islands; for there is every probability that each of the continents is everywhere bounded by the sea. But this is an extent of signification in which the term *island* is not employed; and New Holland is the largest portion of land which is called an island. When a number of smaller islands lie near each other they are said to form a *group* of islands (fig. 9, *b*).

A portion of land which is almost entirely surrounded by water is called a *peninsula* (fig. 9, *c*), as the peninsula of Malacca, the Morea or Grecian Peloponnesus, &c. The term peninsula is often applied to a large extent of country. Thus we speak of Spain as a peninsula. Indeed Africa itself may be considered as a vast peninsula, being connected with Asia only by the narrow isthmus of Suez.

The narrow neck of land which joins a peninsula to the main land, or which connects two tracts of country together, is called an *isthmus* (fig. 9, *d*). The most remarkable isthmuses in the world are, the Isthmus of Suez, which joins Africa and Asia, and the Isthmus of Darien, which connects the continents of North and South America.

A narrow tract of land stretching out into the sea, and appearing to terminate in a point, is called a *cape* (fig. 9, *e*). The most remarkable capes are, the Cape of Good Hope, at the southern extremity of Africa; Cape Horn, at the southern extremity of South America; and the North Cape, at the northern extremity of Europe. A large portion of land jutting out into the sea is called a *promontory* (fig. 9, *f*).

It may assist the memory to keep in view the analogy which subsists between the denominations of land and those of water. The large portions of land called *continents* correspond to the extensive tracts of water called *oceans;* islands are analogous to lakes; peninsulas to seas or gulfs; isthmuses to straits; capes to creeks; and so with the others.

Until of late, in systems of geography, the earth used to be considered as divided into four quarters; Europe, Asia, Africa, and America. A classification in which the whole world is arranged under seven divisions has now however been very generally adopted: These divisions are, Europe, Asia, Africa, North America, South America, Australasia, and Polynesia. With regard to the last two, the one, Australasia, or South Asia, comprehends certain of the great islands, particularly New Holland, which are usually considered as belonging to Asia; and the other, Polynesia, signifying many islands, comprehends all the smaller islands which are scattered over the great expanse of the Pacific Ocean.

This arrangement and classification of the parts of the earth's surface are founded on the most obvious points of distinction. We shall now explain two divisions employed by the ancients, which are founded upon different principles; that into zones, and that into climates.

The division into zones is suggested by the different degrees of temperature which prevail in different regions of the earth. The temperature of a country depends on a variety of circumstances (see PHYSICAL GEOGRAPHY); but of these, one of the most obvious is the position of the sun with regard to the zenith. The more nearly his rays are received vertically, the higher will be the temperature; and, on the contrary, the more obliquely they fall, the less effect will they produce in raising the temperature. Now to every point of the earth's surface between the tropics the sun is vertical twice in the year. It is in this region, then, that the highest temperature will prevail. Again, within the polar circles the sun's rays at all times fall very obliquely; and for a length of time they do not reach these two regions of the globe at all. Here, then, the temperature must be lower than any where else, as all other places enjoy more of the sun's genial influence. In the two regions between the tropics and the polar circles, a medium temperature is found, increasing as we approach the former, and diminishing as we approach the latter. Thus is the earth's surface divided, by the two tropics and two polar circles, into five *zones*, distinguished from one another by the prevailing temperature in each. That between the tropics is called the *torrid zone*, because there the heat is understood to be extreme. This region, which has the equator passing through the middle of it, the ancients, indeed, considered as uninhabitable. The two regions comprehended within the arctic and antarctic polar circles are called the northern and southern *frigid zones*, on account of the severity of the cold which there prevails. The two regions situated between the tropics and the polar circles, the one in the northern hemisphere, bounded by the tropic of cancer and the arctic circle, the other in the southern hemisphere, bounded by the tropic of capricorn and the antarctic circle, are called the northern and southern *temperate zones*, because there neither the heat nor cold is excessive; but the heat reaches the highest temperature of summer, and the cold sinks to the lowest temperature of winter, without either becoming extreme.

As each tropic lies about 23½° from the equator, the breadth of the torrid zone is about 47°, or nearly 3240 English miles. The breadth of each of the frigid zones, that is, from the circumference of the polar circle to the pole, is 23½°, or nearly 1620 miles; so that there remains for the breadth of each of the temperate zones about 43°, or nearly 2970 miles. The superficial content of each zone is easily calculated by the ordinary rules of mensuration. Let s be the surface of a segment of the sphere, d the diameter of the sphere, and h the height of the segment; then

$$s = 3{\cdot}1416\, dh.$$

To apply this formula; let NESQ (Plate CCLIX. fig. 3) be the sphere divided into five zones. It is evident that, for the torrid zone, h must be equal to Ll, or to twice the sine of BE to the radius EC; that for each of the temperate zones h must be equal to LR or lr, the difference of the sines FE and BE to the same radius CE; and that for the space comprehended within each polar circle, h must be equal to NR, the excess of the radius NC above CR, the sine of FE corresponding to the radius. Hence, if we put m for twice the natural sine of the arch BE; for the difference of the natural sines of the arches BE and FE; and for the excess of radius above the natural sine of FE, successively;—since in the case of the terrestrial sphere CE or CN is equal to 3956 miles, we have $h = 3956\, m$. Putting, therefore, instead of d, its value, 7912, and giving the above formula a logarithmic form, we obtain

$$\text{Log.}\, s = \log.\, m + 7{\cdot}9926935.$$

Now, for the torrid zone, $m = 2$ nat. sin. 23° 30′ = ·7975. Hence,

$$\begin{array}{lr} & \text{Log.}\, m = \bar{1}{\cdot}9017307 \\ & 7{\cdot}9926935 \\ \hline s = 78419520 \ldots\ldots\ldots\ldots\ldots & \log. = 7{\cdot}8944242. \end{array}$$

The torrid zone contains, therefore, about 78,419,500 square miles.

Again, for each of the temperate zones, we have m = nat. sin. 66° 30′ — nat. sin. 23° 30′ = ·51831. Hence,

$$\begin{array}{lr} & \text{Log.}\, m = \bar{1}{\cdot}7145896 \\ & 7{\cdot}9926935 \\ \hline s = 50966300 \ldots\ldots\ldots\ldots\ldots & \log. = 7{\cdot}7072831. \end{array}$$

So that each of the temperate zones contains about 50,966,300 English square miles.

Lastly, for the space contained within each of the polar circles we have m = rad. — sin. 66° 30′ = 1 — 0·91706 = ·08294: Hence,

$$\begin{array}{lr} & \text{Log.}\, m = \bar{2}{\cdot}9187640 \\ & 7{\cdot}9926935 \\ \hline s = 8155630 \ldots\ldots\ldots\ldots\ldots & \log. = 6{\cdot}9114575. \end{array}$$

The portion of the surface of the globe comprehended within each polar circle is therefore nearly equal to 8,155,600 square miles.

It is evident that the superficial content of any other zone of the terrestrial sphere may be found by the above formula, by putting m equal to the difference of the natural sines corresponding to the latitudes of the parallels by which the zone is bounded.

If it is required to find the area of a segment of a zone bounded at both extremities by meridians, it is only necessary to find first the area of the whole zone, and then to multiply the result by the number of degrees and parts of a degree in the length of the segment, and to divide by 360. Thus, the number of square miles contained in the portion of the torrid zone terminated by two meridians which are separated from each other by 8° 45′ is equal to $78419520 \times 8\frac{3}{4} \div 360$, which gives 272,290 square miles. By dividg any particular country or district into segments of zones by means of parallels of latitude, its area can easily be calculated.

The division of the earth's surface into climates was employed by the ancients for ascertaining the situation of places. They supposed the northern and southern hemispheres to be each divided into small zones, to which they gave the name of *climates*, the extent and situation of each zone being determined in the following manner. At the equator the day is always equal to the night, and consists therefore of twelve hours. Here the first climate began, and extended to that parallel where the longest day was 12½ hours, which corresponds to 8° 34′ of latitude. Commencing at this same parallel at which the first terminated, the second climate extended to latitude 16° 43′, where the longest day is thirteen hours. Here the third climate began, and was extended in like manner to that parallel where the longest day is 13½ hours. By proceeding in this manner, the space between the equator and each polar circle was divided into twenty-four climates, each of such a breadth as to make half an hour of difference in the length of the longest day at the two parallels of latitude by which the climate was bounded. Having reached the polar circles northward and southward, where the longest day is twenty-four hours, they divided the space within each polar circle in such a manner as to make the difference in the length of the longest day at the beginning and termination of each climate one month. Hence, as the poles are alternately illuminated for six months, there were just six climates within each polar circle.

Table of Climates.

	Climates.	Latitude of the Higher Parallel.		Breadth of the Climate.		Longest Day under the Higher Parallel.	
		Deg.	Min.	Deg.	Min.	Hours.	Min.
Between the equator and either polar circle.	I.	8	34	8	34	12	30
	II.	16	43	8	9	13	0
	III.	24	10	7	27	13	30
	IV.	30	46	6	36	14	0
	V.	36	28	5	42	14	30

	III.	73	39	3	49	3	
	IV.	78	31	4	52	4	
	V.	84	5	5	34	5	
	VI.	90	0	5	55	6	

Besides dividing the surface of the globe into zones and climates, the ancients likewise distinguished the inhabitants of the different regions of the earth by the particular direction in which the shadows of bodies are projected in each region, and by some other circumstances depending on the position of the sun relatively to the zenith or to the meridian. The inhabitants of the torrid zone have their shadows at noon projected, sometimes towards the south and sometimes towards the north, according to the position of the sun in the ecliptic. They were therefore called by the ancients *Amphiscii*, a term derived from αμφι, *about*, and σκια, *a shadow*. In the temperate zones, the sun is at noon always on the same side of the zenith. Hence the shadows of objects at noon always fall in the same direction; in the northern temperate zone towards the north, and in the southern temperate zone towards the south. The inhabitants of these regions were accordingly called *Heteroscii*, from ἑτερος, *different*, and σκια. Within the polar circles the sun does not always rise and set every twenty-four hours, as in the other zones; but for a certain number of days in our summer he never sets to places within the arctic polar circle, nor rises to places within the antarctic; and the contrary takes place for a certain number of days during our winter. The number of days during which the sun is present or absent increases as we advance from the polar circle towards the pole. When the sun continues above the horizon for twenty-four hours or upwards, the shadows will make a complete circuit round the objects from which they are projected; hence the inhabitants of the frigid zones were called *Periscii*, from περι, *about*, and σκια.

Again, the inhabitants of two places which lie under the same meridian, and have the same latitude, but are situated on opposite sides of the equator, were called, relatively to each other, *Antœcii*, from αντι, *opposite to*, and οικια, *a habitation*. At such places the hours of the day will always correspond, but the seasons of the year will be opposite. The inhabitants of two places which have the same latitude, and are situated on the same side of the equator, but under opposite meridians, were called *Periœcii*, from περι, *about*, and οικια. They have always the same season of the year at the same time; but any hour of the day at the one place corresponds to the same hour of the night at the other. The inhabitants of two places which have the same latitude, but are situated on opposite sides of the equator, and under opposite meridians, are called *Antipodes* to each other, from αντι, *opposite to*, and πους, *a foot*. They have always opposite seasons and opposite hours.

CHAP. III.—DESCRIPTION AND USE OF THE GLOBES.

When geographers became familiar with the doctrine of the sphericity and motion of the earth, it was an obvious step to have recourse to an artificial sphere for illustrating that doctrine. From a very early period, accordingly, the instruments called the *terrestrial* and *celestial globes* have been employed for this purpose. A sphere made of metal, ivory, plaster, paper, pasteboard, or some other convenient substance, is suspended in a brass ring NES (Plate CCLX. fig. 1), of somewhat greater diameter, on two pins N, S, upon which it can be made to revolve. The sphere, thus suspended, is placed in a frame BMC, which may be in many respects variously constructed, according to the taste of the workman; but its upper part BC always consists of a broad ring made of metal or wood, and supported in a horizontal position. The inner circumference of this ring is equal to that of the brass circle in which the globe is suspended; and two notches in its inner edge, diametrically opposite to each other, receive the brass ring, which also rests in a groove below, in such a position that the plane of the horizontal ring bisects the sphere. By this arrangement the globe can be made to revolve on its axis, and the brass circle can be made to slide round in its own plane. On the surface of the globe are delineated the equator or equinoctial line, situated exactly in the middle between the two points on which the globe is suspended, and divided into 360 degrees; the ecliptic, divided into twelve signs, and each of these subdivided into thirty degrees; the two tropics; the two polar circles, with as many more parallels to the equator as are found convenient; and generally twenty-four meridians passing through the points of suspension, which represent the poles. The first meridian is usually made to pass through the intersections of the equator and ecliptic, the points of the vernal and autumnal equinoxes; and from the former of these points the reckoning of the degrees on the equator and ecliptic begins. The brass circle in which the globe hangs may be made to represent the meridian of any given point on the surface of the globe, by simply bringing the given point under it by turning the globe round on its axis. Hence the brass circle is called the *universal meridian.* It is divided, by the equator and two poles, into four quadrants, each of which is graduated; and on the semicircle NES (Plate CCLX. fig. 1) the degrees are reckoned from the equator towards either pole, while on the opposite semicircle they are reckoned from either pole towards the equator. On the broad horizontal circle of the frame in which the globe stands are drawn several concentric circles, the outer of which is divided into 365 equal parts, answering to the number of days in the year; whilst the other circles are graduated, the innermost (or rather another circle concentric with it, but larger) being, besides, divided into thirty-two equal parts corresponding to the points of the compass. The circle next the outer edge forms the calendar, and it has the names of the months arranged in order around it, whilst the divisions are distributed so as to mark the number of days in each. The adjacent circle contains the signs and degrees of the ecliptic, so arranged that against each day of the year is found the point of the ecliptic in which the sun is situated on that day. The innermost circle represents the horizon; and the two notches in which the brazen meridian rests pass through the north and south points. It is divided into four quadrants by the cardinal points; and the degrees of the two quadrants, which form the northern semicircle, are reckoned from the east and west points towards the north; while the degrees of the other two quadrants are reckoned from the east and west towards the south.

Such is a general view of the parts which belong alike to both globes, the terrestrial and the celestial. A more minute description seems unnecessary, as a careful inspection of the globes themselves, with their appendages, will convey a much more distinct conception of them than can be given either by description or by drawings. It will be necessary, however, to describe shortly the horary or hour-circle, the quadrant of altitude, and the compass.

The hour-circle is a small circle of brass, divided into twenty-four equal parts corresponding to the hours of the day, the divisions being reckoned in two twelves to suit the hours before and after noon. This circle is fixed on the axis of the globe, having its centre coinciding with the north pole. It can be adjusted with the hand to any meridian, but is at the same time tight enough to be moved along with the globe. Some globes have the hour circle fixed on the meridian, with an index that admits of being adjusted with the hand, but is carried round with the globe.

The quadrant of altitude is a thin flexible slip of brass, equal in length to one fourth part of the circumference of a great circle on the globe. It is graduated on one side, and is furnished with a nut and screw at one end, for the purpose of making it fast to the brazen meridian. Its use is to measure degrees on the surface of the globe in any direction.

The compass is simply a magnetic needle suspended over the centre of a circle, on the circumference of which are marked the thirty-two points of the compass. It is fixed to the under part of the frame in which the globe is suspended, and is used for the purpose of placing the meridian due north and south.

On the terrestrial globe the land and water which compose the surface of the earth are delineated, with the various divisions belonging to each. If we suppose the globe to be six or seven feet in diameter, the true height of the mountains on the earth's surface must be reduced, in order to be represented on the globe in due proportion to its bulk, in the ratio of 7912 miles to six or seven feet; that is, the height of the protuberance on the globe which shall represent any particular mountain must be somewhat about the six millionth part of the actual elevation of the mountain above the general surface of the earth. Apply this to the highest mountain in the world, which does not exceed five and a half miles in height; the elevation of the protuberance representing it on a globe of the supposed dimensions would be about one seventeenth part of an inch above the general surface. It is seldom, however, that globes are made of this size. One third of the supposed diameter is more near to the ordinary dimensions. Hence we see with what propriety the earth is represented by a globe having a smooth surface.

But in order to render the representation more complete, it may be supposed necessary that the terrestrial globe should be enclosed in a hollow sphere which would represent the heavens surrounding the earth on all sides. In conformity with this idea the *armillary sphere* was contrived, in which the several circles of the system of the world, put together in their natural order, are represented, with a small globe in the centre of the sphere to represent the earth. Fig. 3, Plate CCLX., represents a sphere of this description, which will be sufficiently understood by inspection. The ordinary way, however, of representing the heavens, proceeds on the supposition that the eye of the observer is placed, not in the centre of the celestial sphere, but beyond its bounds, so as to look down on a *convex* surface. Thus are the stars and constellations represented in their relative positions on the celestial globe (fig. 2), with which the concave surface of the visible heavens is easily compared.

Besides answering the general purposes of illustration, the globes furnish also the means of resolving with facility, and with a degree of accuracy sufficient for ordinary purposes, many problems in geography and practical astronomy. It is only requisite to consider the circumstances on which the solution of a problem depends, and to arrange on the globe these circumstances, according to their natural order and dependence, and the result is at once obtained. We proceed to give a few of the more useful problems, with their solutions by the globes.

I. *Solution of Problems by the Terrestrial Globe.*

Prob. 1. To find the latitude and longitude of a given place.

Bring the place under the graduated edge of the brazen meridian, then the degree of the meridian immediately over it is its latitude north or south, and the degree of the equator cut by the meridian is its longitude east or west.

Prob. 2. The latitude and longitude of a place being given, to find the place itself on the globe.

Mathematical Geography.

Bring the point of the equator corresponding to the iven longitude to the brazen meridian; under the degree f latitude on the meridian the place is found.

Prob. 3. To find the distance between any two places n the globe.

Lay the quadrant of altitude over the two places, and ark the number of degrees between them. The degrees ay then be converted into English miles, if required, by ultiplying by 69·06.

Prob. 4. The hour at any one place being given, to find hat hour it is at any other place; or to find the differ- ce of longitude between the places in time.

Bring the place at which the hour is given to the bra- en meridian, and set the index, or the hour-circle, to at hour; then turn the globe till the other place comes der the meridian, and the index, or the hour-circle, ill show the hour required. The difference between the me found and the time given is the difference of the ngitudes of the places in time.

Prob. 5. To rectify the globe for a given place.

Elevate the pole that is adjacent to the place as many de- rees above the wooden horizon as are equal to the latitude.

Prob. 6. To find at what hour the sun rises and sets a given place, for any given day.

Rectify the globe for the latitude of the place; find om the wooden horizon the sun's place in the ecliptic r the given day, and bring it to the meridian. Set e index to XII., and turn the globe till the sun's place mes to the eastern edge of the horizon, the index will ow the hour of rising; then turn the globe till the sun's ace comes to the western edge of the horizon, and the dex will show the time of setting.

By doubling the hour of sunrise, we obtain the length the night; and by doubling the hour of sunset, we ob- in the length of the day. It is evident also that the me arrangement of the globe will give the point of the mpass on which the sun rises and sets, by simply ob- rving what point of the circle of rhumbs, on the wooden rizon, is cut by the sun's place in the ecliptic at the ne of rising and setting. Further, by observing when e sun is about eighteen degrees below the eastern and estern parts of the horizon, the time of the beginning the morning twilight, and of the ending of the evening ilight, is found.

Prob. 7. To find the sun's declination for a given day of given month, and to what places the sun will be vertical that day.

Find, on the wooden horizon, the sun's place in the liptic for the given day; bring that point of the ecliptic the meridian, the degree immediately over it on the eridian is the declination north or south. Turn round e globe till it has made a complete revolution; and to ery place which passes under that degree of the meri- an, the sun will be vertical on that day.

Prob. 8. The hour and day being given at a particular ace, to find where the sun is then vertical.

Find the sun's declination by the preceding problem; ing the given place under the meridian, and set the in- x to the given hour; then turn the globe till the index ints to XII. noon; and all the places under the meri- an will have noon at the given time; and that place hich is under the degree of the meridian that corre- onds with the sun's declination will have the sun in the nith.

Prob. 9. The hour and day being given at a particular ace, to find where the sun is then rising or setting, and ere it is noon or midnight.

Rectify the globe for the given place; and having pre- ously found by last problem the place to which the sun vertical at the given time, bring that place to the me- lian. Then, to all the places under the western edge of the horizon the sun is rising, and to those under the eastern he is setting; to those under the upper half of the meridian it is noon, and to those under the lower half it is midnight.

Prob. 10. A place in the torrid zone being given, to find on what two days of the year the sun will be vertical to that place.

Find the latitude of the place; turn round the globe, and note the two points of the ecliptic which pass below the degree of latitude on the meridian. Find in the calendar circle of the wooden horizon the days corresponding to these two points of the ecliptic, and these are the days required.

Prob. 11. To find the sun's meridian altitude at a given place on a given day.

Rectify the globe for the latitude of the place; bring the sun's place for the given day to the meridian; count the number of degrees between that place and the horizon for the altitude required.

Prob. 12. To find the altitude of the sun at any given place and hour.

Rectify the globe for the latitude; bring the sun's place to the meridian, and set the index to XII. noon; turn the globe till the index point at the given hour; fix the quadrant of altitude on the meridian at the degree of latitude, and lay it over the sun's place; count the number of degrees on the quadrant between that point and the horizon for the altitude required.

Prob. 13. To find all the places to which a lunar eclipse is visible at any instant.

Find the place to which the sun is vertical at the given time; rectify the globe for the latitude of that place, keeping the place under the meridian; set the index to XII. noon; then turn the globe till the index point to XII. midnight; the eclipse will be visible to all those places which are above the horizon.

Prob. 14. Any place in the north frigid zone being given, to find how long the sun shines there without setting, and how long he is totally absent.

Rectify the globe for the latitude of the place; bring the ascending signs of the ecliptic to the north point of the horizon, and note at what degree the ecliptic is intersected by that point; find on the wooden horizon the day and month corresponding to that degree; from that day the sun begins to shine continually. Next, bring the descending signs to the north point of the horizon, and by observing at what degree the ecliptic is now cut, and referring to the horizon, we find the time when the sun ceases to shine without setting, which is the termination of the longest day. By proceeding in the same manner with the southern point of the horizon, we will find the beginning and end of the longest night.

Prob. 15. Two places being given, to find the angle which a great circle passing through them makes with the meridian of each.

Rectify the globe for both places successively, bringing in each case the place for which the globe is rectified to the meridian; fix the quadrant of altitude in each operation on the meridian over the place for which the globe is rectified, and lay it over the other place; the two arches intercepted successively on the horizon between the quadrant and the meridian measure the angles required. It is evident, that if both places lie on the same meridian, the angle is 0; and that if both lie on the equator, the angles will be each 90°.

If a ship be supposed to sail from the one place to the other, on a great circle of the terrestrial sphere (which supposition implies that the ship's course is altered every instant), then the one angle found by this problem will be the course with which the ship left the one place, and the other angle the course with which she arrived at the other place. The arch of the great circle intercepted between the places would be the distance sailed.

PROB. 16. To construct a horizontal dial by the globe for a given latitude.

Rectify the globe for the latitude; bring the first meridian under the brazen meridian, and note the arches of the horizon intercepted between the southern point and the several meridians in the eastern and western hemispheres. If the number of meridians drawn on the globe be twenty-four, which is usually the case, the arches intercepted on the horizon will measure the angles which the hour-lines make with the meridian. To find the angles corresponding to half hours and quarters, turn the globe gradually from its position in which the first meridian was under the brazen meridian, noting for each arch of 3° 15′ of the equator that passes under the brazen meridian, the arch of the horizon intercepted between the southern point and the first meridian; the arches thus found give the positions of the lines corresponding to the half hours and quarters. The style of the dial represents the axis of the earth, and must therefore make with the plane of the horizon an angle equal to the latitude of the place.

A direct north or south dial for any latitude may be constructed in the same manner, by considering it as a horizontal dial for a latitude which is the complement of the given latitude.

II. *Solution of Problems by the Celestial Globe.*

PROB. 1. To find the latitude and longitude of any star.

Bring the pole of the ecliptic to the meridian. Then, having fixed the quadrant of altitude over the pole, place it over the given star; the number of degrees between the ecliptic and the given star is the latitude; and the number of degrees between the edge of the quadrant and the first point of Aries indicates the longitude.

PROB. 2. To find a star's place in the heavens, its latitude and longitude being given.

Place the extremity of the quadrant of altitude on the pole of the ecliptic, and make its graduated edge cut the ecliptic in the longitude of the star; then the star will be found under the degree of the quadrant that denotes its latitude.

PROB. 3. To find the right ascension and declination of the sun or of a star.

Bring the sun's place, or the star, to the meridian; the degree of the equator cut by the meridian gives the right ascension, and the degree of the meridian over the sun's place, or the star, shows the declination north or south.

PROB. 4. The latitude of a place, the day and hour being given, to arrange the celestial globe so as to exhibit the appearance of the heavens at that place and time.

Rectify the globe for the latitude of the place; bring the sun's place for the given day to the meridian; set the index to XII.; then turn the globe till the index point to the given hour. In this position, the globe will represent the actual appearance of the heavens.

PROB. 5. To find the time when any of the heavenly bodies rises, sets, or comes to the meridian, on a particular day at a given place.

Rectify the globe for the latitude of the place; bring the sun's place to the meridian, and set the index to XII.; then turn the globe till the star comes to the eastern edge of the horizon; the index will show the time of rising. Next, turn the globe till the given star comes to the western edge of the horizon; the index will show the time of setting. Lastly, bring it to the meridian, and the index will show the time of its culmination or southing.

PROB. 6. To find on what day of the year any given star comes to the meridian at a given hour.

Bring the given star to the meridian, and set the index to the given hour; turn the globe till the index points to XII. noon, and note the degree of the ecliptic cut by the meridian; the day of the month which corresponds to that degree is the day required.

PROB. 7. The latitude of a place, the altitude of a star, and the day of the month, being given; to find the hour of the night.

Rectify the globe for the latitude; bring the sun's place to the meridian, and set the index to XII.; fix the quadrant in the zenith, then move the globe and the quadrant till the star comes under the degree of the quadrant which denotes the given altitude, and the index will show the hour required.

PROB. 8. The year and day being given, to find the place of a planet.

Find the sun's place for the given day, and bring it to the meridian; set the index to XII.; then find in the Nautical Almanack the time when the planet passes the meridian on the given day, and turn the globe till the index points to the hour thus found; find in the almanack the declination of the planet for the same day, and under it on the globe is the place of the planet.

These are a few of the more important problems that can be resolved by the globes, and will be sufficient to illustrate the principle of solution. The solution of problems by the armillary sphere depends upon the very same principles.

CHAP. IV.—OF THE CONSTRUCTION AND USE OF MAPS.

In representing the geographical divisions of the earth's surface, two objects are to be kept in view; on the one hand, to exhibit accurately to the eye the relative position of the different countries; and, on the other hand, to give a delineation sufficiently minute to furnish a distinct knowledge of the necessary details. As the globe has very nearly the exact figure of the earth, the representation which it affords of the surface fulfils the first of these objects in the most perfect manner; but to attain the second it would be requisite to enlarge the globe beyond all convenient size. A globe of the ordinary dimensions serves almost no other purpose in this respect, but to convey a clear conception of the earth's surface as a whole; exhibiting the figure, extent, position, and general features of the great continents and islands, with the intervening oceans and seas. To obtain a detailed representation of any part of the earth's surface, geographers have therefore found it necessary to have recourse to *Maps,* in which countries are delineated on a plane, while the mutual proportions of the distances of places are preserved as nearly as possible the same as on the globe.

For the construction of maps different mathematical hypotheses have been adopted.

By one method of construction, that of *projection,* the boundaries of countries, and their more remarkable features, are represented according to the rules of perspective, on the supposition of the eye being placed on some point of the sphere, or at some given distance from it, which may be increased indefinitely. Wherever the eye is supposed to be situated, the representation thus obtained answers very well, provided the surface to be represented is of small extent, and the point of view, or *projecting point,* is nearly over the centre; but when the surface is of great extent, for example, a whole hemisphere, those places which are situated near the border of the projection are in all of them much distorted.

Another method, that of *development,* is founded on the supposition that the spherical surface to be represented is a portion of a cone, of which the vertex is situated some-were in the polar axis produced, and the conical surface is supposed either to touch the sphere in the middle parallel of the map, or to fall within the sphere at the middle parallel, and without it at the extreme parallels. The surface of the cone is then supposed to be spread out into a plane.

A third method, which depends on the development of a cylindrical surface, is that according to which maps are so delineated as to have the parallels of latitude and circles of longitude respectively represented by parallel straight lines. By this method marine charts are constructed. As the rhumb makes equal angles with every meridian, it necessarily, according to this method of delineation, becomes a straight line. Such a representation of the earth's surface is commonly called *Mercator's Chart*, although the invention is due to an English mathematician, Edward Wright.

These are the three principal methods employed to represent to the eye the several countries on the surface of the earth.

I. *Construction of Maps by Projection.*

The representation of any portion of the earth's surface obtained by projection, varies, of course, its character according to the several situations of the eye and of the plane of projection, in relation to the meridians, parallels, and various points or places so represented. It is usual to assume the plane of a great circle of the sphere as the plane of projection, and to suppose the eye situated at some point in a straight line perpendicular to this plane, and passing through the centre of the circle. If the distance of the eye from the plane of projection be supposed indefinitely great, the projection is called the *orthographic ;* if it is supposed to be upon the surface of the sphere, the projection is called the *stereographic ;* and if the eye is supposed to be in such a position, that the projections of the meridians and parallels of latitude are nearly equidistant, as the meridians and parallels themselves are upon the globe, the projection is called the *globular*. In order to apply these projections to the construction of maps, we must attend to the properties of each.

1. *Orthographic Projection of the Sphere.*

The fundamental principle in this projection is, that the representation of any point on the sphere is where a perpendicular from that point meets the plane of projection. Hence it follows that the projection of a line of any kind is determined by supposing perpendiculars to fall from every point in that line upon the plane of projection, and a line to pass through the points of intersection of these perpendiculars with that plane.

If the proposed line be a straight line, its orthographic projection will also be a straight line, being the intersection of the plane of projection with the plane perpendicular to it passing through the proposed line.

If the proposed line be the circumference of a circle parallel to the plane of projection, its orthographic projection will also be a circle of the same diameter ; since the circle and its projection are the equal and parallel extremities of the cylinder formed by the perpendiculars falling upon the plane of projection.

If the proposed line be the circumference of a circle, of which the plane is perpendicular to the plane of projection, its orthographic projection will be a straight line equal to its diameter.

If the proposed line be the circumference of a circle, of which the plane is neither parallel nor perpendicular to the plane of projection, its projection will be an ellipse, being the curve in which the plane of projection intersects the cylinder formed by the perpendiculars falling upon it from every point in the circumference of the circle.

Mathematical Geography.

An accurate idea of the orthographic projection of any line or figure may be obtained by holding it up in the light of the sun, and observing the shadow formed on a plane perpendicular to the direction of the sun's rays. The rays which pass close to the figure are the perpendiculars to the plane of projection, and the shadow is the orthographic projection of the figure.

From the nature of this projection, the orthographic representation of half the surface of the globe shows nearly the true figure and proportions of countries about the middle of the map, that is, directly opposite to the supposed position of the eye ; but towards the extremities the true figure and position of the countries are imperfectly exhibited. For this reason this method of projection is seldom employed in geography, but in astronomy it is frequently used. We shall give, however, the orthographic projection of the sphere on the plane of the equator and on the plane of the meridian.

To project the Sphere orthographically on the Plane of the Equator. From any point C as a centre, with any radius CA (Plate CCLX. fig. 4), describe the circle ABD. Let this circle represent the equator, upon the plane of which it is required to project the sphere orthographically. It is evident that the centre C will be the projection of the poles of the equator, and that since the planes of the meridian circles are perpendicular to the plane of the equator, these circles will be projected into diameters, making with each other the same angles as do the planes of the meridians. Let A 90, B 180, be two perpendicular diameters ; they will represent two meridian circles at right angles to each other : divide the semicircle B 90 D into twelve equal parts at the points 15, 30, 45, &c., and let diameters be drawn through the points of division ; then the twenty-four radii CB, C 15, C 30, &c. will be the projections of the twenty-four meridians usually drawn upon the globe, any one of which, as BC, may be considered as the first meridian.

Next, it is evident that the parallels of latitude will be projected into circles, which have C for their common centre, and of each of which the radius will be equal to that of the corresponding parallel of latitude, or to the cosine of the latitude of the parallel. Let us suppose that a parallel is drawn on the globe for every tenth degree of latitude ; then divide the quadrant AB into nine equal parts, at the points 80, 70, 60, &c. ; from these points of division let fall perpendiculars upon BC, meeting it in the points 80, 70, 60, &c. ; the lines C 80, C 70, C 60, &c. are equal to the cosines of the arches B 80, B 70, B 60, &c. to the radius BC. From the centre C, therefore, describe circles with these lines as radii ; and these circles will be the projections of the parallels corresponding to the 80th, 70th, 60th, &c. degrees of latitude.

Lastly, the projections of the polar circles and of the tropics may be found by setting off from the point A towards B, and from the point B towards A, twenty-three and a half degrees, drawing perpendiculars to BC through the points of division, and describing circles from C as a centre through the points in which these perpendiculars cut BC.

Thus will the projection of the sphere upon the plane of the equator be completed. The representation given of the polar regions in a map of this description is tolerably correct, but the countries towards the equator are very much distorted.

To project the Sphere orthographically on the Plane of the Meridian. From any point C as a centre, with any distance CA (Plate CCLX. fig. 5), describe a circle PASB, to represent the meridian circle, on the plane of which it is required to project the sphere orthographically. Draw the diameters PS and AB at right angles to each other : then may PS be assumed as the projection of the meridian which is at right angles to the plane of projection; and AB will be the projection of the equator, since that circle cuts all the meridians at right angles. The other meridians cutting the projecting plane obliquely are projected into ellipses, having PS for their common transverse axis, and the cosines of their inclinations to the projecting plane for their several semiconjugate axes. Let the quadrant AS be therefore divided into six equal parts in the points 15, 30, &c. from which let 15*m*, 30*n*, &c. be drawn perpendicular to AC, and meeting it in *m*, *n*, &c. Describe the ellipses P*m*S, P*n*S, &c. having a common transverse axis PS, and C*m*, C*n*, &c. for their semiconjugate axes: these ellipses are the projections of the meridians passing through every fifteenth degree of the equator.

Again, to project the parallels of latitude: Divide either of the quadrants AP or BP into nine equal parts, in the points 10, 20, 30, &c. and draw through the points of division straight lines parallel to AB, the projection of the equator: these lines are the projections of the parallels on the one side of the equator to every tenth degree of latitude. The parallels on the other side of the equator are to be drawn in the same manner; as are also the tropics and polar circles, the former at 23½° on each side of the equator, and the latter at 23½° from the poles.

In this projection there is great distortion in the appearance of the regions about the poles, and of all the countries near the meridian PASB. It is as we approach the centre of the map that this distortion begins so far to disappear as to allow a projected portion of the earth's surface to acquire any considerable resemblance to its delineation on the globe.

2. *Stereographic Projection of the Sphere.*

In the stereographic projection of the sphere the eye is supposed to be situated at one of the points where the surface of the sphere is intersected by a straight line passing through the centre, and perpendicular to the plane on which the projection is to be made. This plane, as we have already remarked, is that of a great circle of the sphere; so that the point on the sphere at which the eye is supposed situated will be everywhere 90° distant from the circumference of that circle whose plane is assumed as the plane of projection. In order that the lines and circles on the sphere may be visible to the eye in this position, it will be necessary to suppose the sphere to be transparent. Let, then, ABEC (Plate CCLX. fig. 6) be a great circle drawn on a sphere of this description, and passing through the eye at E. Let FG be a plane passing through *a*, the centre of the sphere, in such a manner as to cut the plane of the circle ABEC at right angles in the diameter HK, and to make each of the arches EH, EK, equal to 90°: then FG will be the plane of projection. Draw EA the diameter of the sphere passing through the eye; also draw EB, EC, to B and C, any two points in the circumference of the circle ABEC; and let the lines EA, EB, EC, intersect the plane FG in the points *a*, *b*, *c*. By the fundamental principle of the stereographic projection, namely, that the representation of any point is where the straight line drawn from it to the eye intersects the plane of projection, the points *a*, *b*, *c* are the projections of the points A, B, C. It is evident also that the line *bc*, in which the planes EBC and FG intersect each other, is the projection of the line BC, or of the arch BAC; and that the lines *ab*, *ac*, are the projections of the arches AB, AC.

Since E*ab* is a right angle, *ab* is the tangent of the angle *a*E*b* to the radius E*a*. But the angle *a*E*b* is measured by half the arch AB: hence *ab* is the tangent of half the arch AB, or its semitangent. Thus it appears, that if a great circle pass through the projecting point E, any arch of it reckoned from the opposite point of the sphere is projected into a straight line passing through the centre, and equal to the semitangent of that arch.

Let BDC be any circle drawn on the sphere, and having BC for a diameter. Take D any point in the circumference of that circle, and draw ED intersecting the plane FG in the point *d*. If the point D be carried round the circumference BCD, the line ED will trace the surface of a cone of which BDC is the base; and the line *bdc*, (the intersection of the plane FG with the conical surface), which is traced by the point *d*, is the projection of the circle BCD.

Now, it can be demonstrated that the angles EBC, ECB, are equal to E*cb*, E*bc*, each to each; so that the cones EBC, E*bc* are similar. Hence the projection *bdc* is a circle, whose diameter *bc* is found by taking *ab* and *ac* equal to the semitangents of the arches AB, AC.

Thus it appears that every circle of the sphere is, according to the stereographic projection, represented by a circle; but a circle can be described when three points in the circumference are given, or when two points in the circumference and the radius are given. Hence this property renders the projection of the sphere by this method very easy.

Another very elegant and important geometrical property of this projection is, that any two straight lines touching the sphere at one and the same point are represented by two straight lines which make with each other on the plane of projection an angle equal to that contained by the touching lines themselves. Hence also the angle formed by any two circles of the sphere is equal to the angle formed by their projections.

When it is further considered that the stereographic projection gives a representation of a hemisphere, in which the parts about the extremity of the map are less distorted than in the representation obtained by the orthographic projection, it must be concluded that the former method is preferable to the latter.

To project the Sphere stereographically on the Plane of the Equator. Upon C as a centre (Plate CCLX. fig. 7) describe a circle ABGE to represent the equator, on the plane of which it is required to project the sphere; or rather that hemisphere which lies remote from the point of sight. As the eye must be supposed to be situated at the pole, it is evident that the centre C will be the projection of the opposite pole, and that the meridians will be projected into straight lines passing through C, and dividing the circumference of the circle ABGE into as many equal parts as there are meridians supposed to be drawn on the globe. If there are twenty-four meridians, then draw AG any diameter, and divide the semicircle AEG into twelve equal parts. Through the points of division draw diameters, as BCE, FCK, DCH, &c., and the radii thus found will be the projections of the meridians corresponding to every fifteenth degree of the equator, any one of which may be assumed for the first meridian.

Again, to project the parallels of latitude; let AG and BE be perpendicular diameters. Divide the quadrant AB into nine equal parts in the points 10, 20, 30, &c. From E to the several points of division draw straight lines intersecting AC in the points 10, 20, 30, &c. The lines C 10, C 20, C 30, &c. are the semitangents of the distances of the several parallels of latitude from the pole. Hence the points 10, 20, 30, &c. are the points of intersection of the projected parallels with the projected meridian AG. Upon C, then, as a centre, at the distances C 10, C 20, C 30, &c. describe concentric circles, and these will be the projections of the parallels corresponding to every tenth degree of latitude. The tropics and polar circles are found in the same manner.

To project the Sphere stereographically on the Plane of

Meridian. From the centre C (Plate CCLX. fig. 8), with any radius CA, describe the circle ASBP to represent the meridian on the plane of which it is required to project the sphere stereographically. As the eye, in this case, is supposed to be situated at a point in the equator, that circle will be projected into a straight line passing through the centre C: let it be represented by the diameter AB. Draw the diameter PS perpendicular to AB; then will PS represent the meridian passing through the eye, and P and S will be the poles. To project the other meridians, divide the quadrant AP into nine equal parts (supposing a meridian to pass through every tenth degree of the equator) at the points 10, 20, 30, &c., and from S draw straight lines to these points of division intersecting AC in the points 1, 2, 3, &c. The lines C 1, C 2, C 3, &c. are the semitangents of the arcs of the equator which measure the distances of the points in which the several meridians cut the equator from the point of the sphere opposite to the eye. Hence the points 1, 2, 3, &c. are the points in which the projected meridians will intersect the projected equator AB. But the projected meridians also pass through the points P and S. In each, therefore, there are three points given. If we describe, then, the arches P 1 S, P 2 S, P 3 S, &c. these arches will be the projections of the meridians on one side of that passing through the point opposite to the projecting point, and those on the other side are to be found in like manner.

Again, by dividing each of the quadrants PA, PB into nine equal parts, we find two points in each of the parallels of latitude. A third point in each will be found by drawing straight lines from B to each of the points of division 80, 70, 60, &c. so as to intersect PC in the points 8, 7, 6, &c.; for the lines C 8, C 7, C 6, &c. are the semitangents of the arcs intercepted upon that meridian of which PS is the projection between the several parallels and the point of the sphere opposite to the projecting point. Describe, then, the several arches through the three points found in each; and in this manner the parallels on one side of the equator are found. Proceed in the same manner with regard to the parallels on the other side of the equator, and with regard to the tropics and polar circles, and the projection will be completed. It is evident that the centres of all the projected meridians will lie in the line AB, or in that line produced; and from the construction it is easy to show that the distance of the centre of each projected meridian from the point C is equal to the tangent of the inclination of the meridian to the plane of projection; while the radius of the projected meridian is equal to the secant of the same angle.

Further, the centres of all the projected parallels of latitude lie in the line PS, or in PS produced; and the centre of each projected parallel is distant from C by the secant of the arch which measures the distance of the parallel from the pole; while the radius of the projected parallel is equal to the tangent of the same arch.

To project the Sphere stereographically on the Plane of the Horizon for a given Latitude. We must here suppose the eye to be situated at the point of the sphere opposite to the place of which the latitude is given. From the centre C (Plate CCLX. fig. 9), with any radius CN, describe a circle NWSE to represent the horizon upon which it is required to project the sphere. To avoid intricacy among the lines necessary to be drawn for the construction, let the subsidiary circle N′W′S′E′ (Plate CCLXI. fig. 1) be described with the same radius. Through C, the centre of each circle, draw two diameters WE, NS (Plate CCLX. fig. 9), and W′E′, N′S′ (Plate CCLXI. fig. 1), intersecting each other at right angles. Let the diameters NS, WE (Plate CCLX. fig. 9) be the projections of the meridian of the given place, and of a semicircle at right angles to that meridian, and passing also through the given place. It is evident that the points N, W, S, E are the four cardinal points of the horizon. On the circumference of the subsidiary circle N′W′S′E (Plate CCLXI. fig. 1) take N′P′ equal to the given latitude; and draw the straight line W′P′ intersecting CN′ in P: then will CP be the semitangent of the distance of the pole from the point on the sphere opposite to the projecting point. Make therefore CP (Plate CCLX. fig. 9) equal to CP (Plate CCLXI. fig. 1), and the point P is the projection of the pole. Draw the diameters P′*p*, FA′ (Plate CCLXI. fig. 1) at right angles to each other; then will E′A′ be equal to the latitude; and by drawing W′A′ to intersect CS′ in A, we obtain CA the semitangent of the distance of the point in which the equator intersects the meridian from the point of the sphere opposite to the projecting point. Make CA (Plate CCLX. fig. 9) equal to CA (Plate CCLXI. fig. 1); and through the three points W, A, E, describe an arch of a circle: the arch WAE will be the projection of the equator. Next, we shall show the manner of drawing the parallels of latitude, by taking as an example the two parallels which are twenty and forty degrees distant from the pole. In the subsidiary circle (Plate CCLXI. fig. 1) take P′ 20 and P′ 40, equal to 20° and 40° on each side of P′. Draw from W′ to the points thus found, straight lines intersecting CN′ and CS′ in the points *a*, *b*, and *c*, *d*. The lines *ab* and *cd* are the diameters of the projected parallels corresponding to 50° and 70° of latitude. Make C*a*, C*b*, C*c*, C*d* (Plate CCLX. fig. 9) equal to C*a*, C*b*, C*c*, C*d* (Plate CCLXI. fig. 1) respectively, and upon *ab* and *cd* as diameters describe circles; these circles are the projections of the parallels required. In the same manner are the other parallels of latitude, the tropics, and the polar circles to be drawn.

Again, to project the meridians; the straight lines NP, PS, are the projections of the opposite meridians which pass through the north and south points of the horizon. The meridian circle, which is at right angles to that represented by NS, passes through the east and west points of the horizon, so that three points in its projection are given, namely, the points W, P, E; its projection may therefore be drawn. But it may be more conveniently found by considering that the meridian in question makes with the plane of projection an angle equal to the given latitude: the centre of its projection, which is in CS produced, must therefore be distant from the point C by the tangent of the given latitude, and its radius will be equal to the secant of the same. From the point S′ (Plate CCLXI. fig. 1) draw S′D, touching the circle in S′, and meeting P′*p* produced in D; then DS′ and DC are the tangent and secant of the given latitude. In CS produced (Plate CCLX. fig. 9) take CB equal to DS′; and on B as a centre describe an arch through the point P, which will also pass through W and E. The arches PW, PE will represent the opposite meridians, which are at right angles to the meridian of the place for which the projection is made. With regard to the other meridians, it is not difficult to see that their centres will lie in a straight line GH (Plate CCLX. fig. 9) drawn through B at right angles to CB; and that the distance of the centre of each projection from the point B will be equal to the tangent of the inclination of the corresponding meridian circle to that meridian circle which passes through the east and west points; while the radius of the projection will be equal to the secant of the same inclination. Let us suppose, then, that the meridians are to make with each other angles each equal to 15°: at the point P make the angles BP 15, BP 30, &c. equal to 15°, 30°, &c. respectively, and let P 15, P 30, &c. meet the line GH in the points 15, 30, &c. Upon these points, as centres, describe through the point P the arches *m*P*m*′, *n*P*n*′, &c.; then will P*m*, P*n*, &c. P*m*′, P*n*′, &c. be the projected meridians required. In this manner the projection may be completed.

3. *Globular Projection of the Sphere.*

In the globular projection of the sphere, a point is assumed for the position of the eye, at a finite distance from the centre greater than the radius, and so situated that the degrees in the representation shall be nearly equal to each other, and the deviations from equality in the representations of equal portions of the spherical surface thus in some measure corrected. To determine the position of the point of view so as to answer these conditions, let ADBF (Plate CCLXI. fig. 2) be a section of the sphere made by a plane passing through C the centre, and through the point E which is assumed as the projecting point required. Through C draw EB, meeting the circumference ADBF in A and B, and draw the diameter DF at right angles to EB. Bisect the quadrant DB in I, and draw EI meeting DC in G; the point G will be the projection of the point I. But by hypothesis the projections of equal arches are nearly equal: let then DG be assumed equal to GC. Join DB, and draw CI meeting DB in H. Join GH, and draw IK parallel to DC, or at right angles to AB. Then it is evident that DH is equal to HB; and therefore DH : HB : : DG : GC. Hence the line GH is parallel to CB; and we have IH : HC : : (IG : GE : :) KC : CE. But IH is equal to BK, and HC to KC: therefore BK : KC : : KC : CE, and we have $BK \cdot CE = KC^2 = IK^2 = BK \cdot KA$. Hence CE is equal to KA; and taking away the common part AC, there remains EA equal to KC or to IK: that is, EA, the distance of the point of view above the surface, is equal to the sine of 45°. If the radius CA be divided into 100 equal parts, EA is therefore nearly equal to 71 of these parts.

This projection was first suggested by M. Delahire, and the approximation which it gives to equality in the projection of equal arches of a circle perpendicular to the plane of projection is considerable. The circles of the sphere are, according to this method of projection, represented by ellipses. An approximation to this method is, however, generally all that is aimed at. The circles of the sphere are represented by circles; and, without any regard to the distance of a projecting point, the degrees of longitude on the equator and of latitude on the meridian are made all equal to one another; the plane of the meridian being assumed as the projecting plane. The following is the construction by which such a representation of a hemisphere of the earth's surface is obtained.

From the centre C (Plate CCLXI. fig. 3), with any radius CA, describe a circle PASB to represent the meridian on which it is required to project the hemisphere. Draw the diameters AB, PS, at right angles to each other; and let PS represent the meridian of which the plane is at right angles to the plane of projection: then AB will be the projection of the equator, and the points P and S, the projections of the poles.

To project the parallels on the north side of the equator, divide each of the quadrants PA, PB, into nine equal parts: also divide the radius CP into the same number of equal parts. Let 80, 70, 60, &c. *d, e, f,* &c. be the points of division: the parallel corresponding to 80° of latitude will pass through the three points 80, *d*, 80; that corresponding to 70° of latitude through the three points 70, *e*, 70, and so on. Describe circles, accordingly, through these points, and the parallels on the north side of the equator will be drawn. In the same manner are the parallels on the south side of the equator to be projected, as are also the tropics and polar circles.

Again, to project the meridians, divide the radius AC into six equal parts in the points *a, b, c,* &c., and through the points P and S, and these points of division, describe circles P*a*S, P*b*S, &c. Proceed in the same manner on the other side of PS, and the circles thus described will represent the meridians passing through every fifteenth degree of the equator, any one of which may, in laying down places by their latitudes and longitudes, be assumed for the first meridian. Plate CCLXII. is a planisphere, or map of the world, projected in this manner.

II. *Construction of Maps by Development.*

The practical application of the three methods of projection which we have now explained, to the construction of maps, is usually confined to the representation of a hemisphere; whilst for the delineation of the geographical features of a single country, the method of development is commonly employed. The particular purpose for which a map is to be used may make it more or less important that it should exhibit, with all the precision that can be attained, some particular features of the country represented. The purposes of civil government require maps that give the true figure and dimensions of territory. For military affairs, maps that give correct distances are chiefly useful; whilst for the purposes of the navigator, the bearings of places, one from another, must be correctly, and, at the same time, simply exhibited. The first two objects are nearly gained in ordinary maps. But, for the attainment of the last, a map of a peculiar construction, called *Mercator's Chart,* has been invented; which, while it answers completely the purpose of the navigator, is not immediately applicable to any other.

It is an obvious property of a cone and of a cylinder, that the surface of each admits of being spread out on a plane. If a cone be laid with its slant side on a plane, the former will coincide with the latter along a line stretching from the point of contact in the base to the apex of the cone. Hence, if the cone is rolled round, whilst the apex continues at the same point, every point upon the surface of the cone will come in contact with a corresponding point in the plane surface; so that a sector of a circle will be described, with which the surface of the cone, if expanded, would exactly coincide. A cylinder admits of being rolled along a plane surface in a similar manner. But this is not the case with respect to a sphere. For, since a sphere touches a plane only in a point, if the former be rolled along the latter in one direction, the successive points of contact will mark out a straight line. A narrow zone of the sphere may, however, be supposed, without great error, to coincide with the surface of a cone or cylinder; and this hypothesis gives rise to a twofold construction by development, that by the development of a conical surface, and that by the development of a cylindrical surface.

1. *Development of the Curve Surface of a Cone.*

Let NAMB (Plate CCLXI. fig. 4) be a section of the sphere by the plane of the meridian. Let NM represent the axis; then AB drawn through the centre C, at right angles to NM, will represent the diameter of the equator. Take EF, any arch of the meridian, and bisect it in the point G. Through G draw LD a tangent to the circle NAMB, and meeting the axis MN produced in the point L. Let the plane figure LGMB be now supposed to revolve about the axis LM; then will the circle NAMB generate a sphere, and the line LD will generate a conical surface, which will touch the sphere. Further, the points E, G, F will describe circles, which will be parallels of latitude. If EF be an arch of not many degrees, the zone comprised between the parallel circles E*e*, F*f* will nearly coincide with the corresponding portion of the conical surface intercepted between the planes of the same circles. Take any point H in the circumference of the circle described by G, the middle point of the arch E , and join LH, HK, the point K being the centre of the circle GH*g*.

Let us now suppose the conical surface comprehended between the straight lines LG, LH, and the arch GH, to be spread out into a plane L′G′H′. Then it is evident that the arch GH on the middle parallel, of which the radius is HK, the cosine of the middle latitude, is changed into an arch G′H′ of which the radius is L′G′ = LG, the cotangent of the middle latitude. In the line L′G′, and in L′G′ produced, take G′F′, G′E′ equal to the arch EG or G . Then, on the point L′ as a centre, at the distances L′ , L′F′ describe the arches E′*r*, F′*s*, and the plane surface E′F′*sr* may be considered as nearly equal to the spherical surface comprehended between the meridians passing through G and H, and the arcs of the parallels E*e*, F*f* intercepted by these meridians. Hence, if any tract of country situated on the corresponding portion of the earth's surface be delineated on the plane E′F′*sr*, the representation of it thus obtained will bear a near resemblance to its delineation on the globe, the resemblance increasing according as the zone comprehended between the extreme parallels is diminished in breadth.

Such is the principle of the conical development. Let us now consider how the line L′G′and the angle G′L′H′ are to be determined, so as to suit the space E′F′*sr* to any given difference of longitude and given middle latitude; also in what manner the parallels of latitude and the meridians are to be drawn on that surface.

We have already seen, that L′G′ is equal to the cotangent of the middle latitude to the radius of the sphere. If the radius of the sphere be considered equal to unity, the trigonometrical tables will give the length of L′G′ in parts of the radius. But it will be more convenient to have it expressed in minutes of a degree. Now, since the semicircumference is to radius as 3·1416 is to 1, if we put R for radius, we have 3·1416 : 1 : : 180 × 60 : R = 3437·7, which is the radius expressed in minutes of a degree. Hence L′G′ expressed in the same manner will be equal to

3437·7 × cotan. middle latitude.

Again, since the arch GH is equal in length to the arch G′ by hypothesis, the angle GKH measured by the former, must be to G′L′H′ measured by the latter, as the radius L′G′ is to the radius GK; that is, if we put D for the difference of longitude, and φ for the angle G′L′H′, we will have D : φ : : (L′G′ : GK : : cot. mid. lat. : cos. mid. lat. :) rad. : sine mid. lat. Hence we obtain

$$\varphi = D \times \text{sine mid. lat.}$$

The angle L′ being thus determined, and the lines L′G′, G′ , G′F′ being known, and expressed in minutes of a degree, we can describe the figure E′F′*sr*, so that it shall be accommodated to any given middle latitude and given difference of longitude. Then having divided E′F′ into as many equal parts as there are minutes in the difference of latitude, or as there are some given number of minutes in it, the points must be ascertained through which the parallels intended to be drawn pass, and from L′ their common centre, these parallels are to be drawn accordingly. The parallels E′*r*, F′*s* are in like manner to be divided each into as many equal parts as there are minutes, or some given number of minutes, in the difference of longitude: and points being ascertained in each of these parallels through which the meridians proposed to be drawn pass, the straight lines joining the corresponding points are the meridians required. It is by this method that common maps of particular countries are constructed.

As an example, let it be required to construct a map of Great Britain and Ireland, which must extend from 50° of latitude to about 61° north, and from 2° east to about 11° west longitude.

To find L′G′, L′E′, L′F′.

61° 61°
50° 50°

2)111 2)11 = diff. of lat. = 660′

55° 30′ = mid. lat. 5° 30′ = 330′ = G′E′ or G′F′.

Log. cot. mid. lat. 55° 30′, 9·8371343
3437·7..........log. 3·5362680

L′G′ = 2362′·7........log. 3·3734023
G′E′ or G′F′ = 330′·0

L′E′ = 2692′·7
L′F′ = 2032′·7

To find the angle G′L′H′.

Log. sine mid. lat. 55° 30′..............9·9159937
Diff. of long. = 13° = 780′.......log. 2·8920946

Angle G′L′H′ = 643′ = 10° 43′.....log. 2·8080883

To find the chords of the arcs E′*r*, F′*s*.

$$\text{Chord of arc } E'r = \begin{cases} 2L'E' \ldots\ldots\ldots\ldots \text{log. } 3{\cdot}7312180 \\ \times\ \text{sin. } \tfrac{1}{2} L' \ldots\ldots\ldots\ldots 8{\cdot}9695999 \end{cases}$$

Chord of arc E′*r* = 502′·1 ....log. 2·7008179

$$\text{Chord of arc } F's = \begin{cases} 2\,L'F' \ldots\ldots\ldots\ldots\ldots \text{log. } 3{\cdot}6091033 \\ \times\ \text{sin. } \tfrac{1}{2} L' \ldots\ldots\ldots\ldots\ldots 8{\cdot}9695999 \end{cases}$$

Chord of arc F′*s* = 379′·1............log. 2·5787032

Having now determined the four sides of the trapezoid formed by the meridians E′F′ and *rs*, and the chords of the arches E′*r*, F′*s*, it is easy to describe that trapezoid, the length of the sides being measured on any convenient scale of equal parts, which is to be considered as a scale of minutes of a degree on the meridian. Let it be described accordingly (Plate CCLXI. fig. 5), and let the sides E′F′, *rs*, be produced to meet in a point, which will be the point L′. Then, from that point as a centre describe the arches E′*r*, F′*s*, and divide these arches each into thirteen equal parts, since the difference of longitude is 13°. Also, divide E′F′ and *rs* each into eleven equal parts corresponding to the given difference of latitude 11°. Having fixed upon the number of meridians and parallels of latitude that are to be drawn, describe from the point where the lines E′F′, *rs*, intersect when produced, as a centre, the parallels through the proper points of division in E′F′ or *rs*; and draw straight lines joining the proper corresponding points of division in E′*r*, F′*s* for the meridians: we shall here suppose the meridians and parallels to be drawn for every second degree. Number the degrees of latitude and longitude as in the figure, and the map is prepared for having traced upon it the outline of the coasts of the British isles, and places laid down according to their latitudes and longitudes.

It is evident that if the point in which E′F′ and *rs* intersect each other becomes very distant, it may be exceedingly troublesome, or practically impossible, to describe from it as a centre the parallels of latitude. An obvious remedy for this inconvenience is, to join together two rulers, as AB, AC (Plate CCLXI. fig. 6), at the point A, in such a manner as that they may contain an angle equal to the angle in the segment which has for its arch the parallel to be drawn. If the edges of the rulers be made, by means of two pins, to slide over the extremities D, E of the parallel, a pencil fixed at the angular point A will trace the parallel on the map. In the present instance the rulers must be placed so as to form an angle of $\left(\frac{360^\circ - 10^\circ\ 43'}{2} = \right)$ 174° 38′ 30″.

The conical development has been variously modified, so as to remove as much as possible its defects. Thus, one modification was given by the Rev. Patrick Murdoch in the *London Philosophical Transactions*, 1758. He supposed the cone to pass through points of the meridian between the middle latitude and the extremities of the arch to be projected, its side being parallel to the tangent at the middle latitude, while the points where the cone intersects the meridian are so situated as that the conic surface is exactly equal to the spherical surface which it represents. Let M denote the arch of the meridian to be represented in the map; then, according to this method of development, L′G′, the radius of the middle parallel on the map, is equal to

$$\frac{\text{chord of arch M}}{\text{arch M}} \times \text{cot. mid. lat.}$$

the cotangent being supposed to be expressed by the radius of the sphere. In other respects the construction is the same as in the ordinary conical projection.

But the simplest and most successful method of remedying the defects of the conical development is that known by the name of *Flamsteed's projection.* The English astronomer by whom this method was invented, and whose name it bears, made use of it in constructing his celestial atlas. He developed all the parallels of latitude on the sphere into straight lines, and also one of the meridians, namely, that which passes through the middle of the chart. To this meridian the lines representing the parallels are perpendicular, and the length of each is the same with that of the parallel on the sphere which it represents. Dividing the parallels in the projection into equal parts, in like manner as the parallels on the sphere are divided, he supposed curved lines to be drawn through the corresponding points of division, and these curve lines represent the meridians. Flamsteed employed this projection in representing the position of the stars; but it is also made use of in geography, particularly for the delineation of countries which extend on both sides of the equator.

To suit it more effectually to this purpose, it has undergone, however, a modification of very considerable importance, as it corrects in some measure the distortion in the figure of countries lying near the extremities of the map, which arises from the obliquity of the curve lines representing the meridians to the straight lines representing the parallels of latitude, which increases as the former recede from the centre of the map. On the globe the meridians cut all the parallels of latitude at right angles; and by employing concentric circles instead of straight lines, as in Flamsteed's projection, to represent the parallels of latitude, the curves representing the meridians on the map may be made more nearly to fulfil this condition. For this purpose the common centre of the circles, which is situated in a straight line drawn through the middle of the map as an axis, is so assumed that the radius of the middle parallel of latitude is equal to the cotangent of the middle latitude; an assumption which diminishes as much as possible the obliquity of the angles made at the intersections of the curves which represent the meridians, with the circles which represent the parallels. In the position of the common centre of the circles representing the parallels of latitude, this modified projection of Flamsteed coincides with the ordinary conical projection.

We shall exemplify this construction by showing how to describe, according to it, the parallels and meridians for a map of Europe.

Let the map be supposed to extend from 35° to 70° north latitude. Hence the middle latitude will be 52° 30′, and the radius of the middle parallel of the map (being equal to 3437′·7 × cot. 52° 30′) will be equal to 3637′·8. Draw, then, any line LE (Plate CCLXI. fig. 7) for the axis of the map; and assuming any point C for the point of intersection of the axis with the parallel of middle latitude, set off the length of the radius of that parallel from C to L, taken from any convenient scale of equal parts, which is to be considered as a scale of minutes of a degree. Thus the point L, the common centre of the circles representing the parallels, is determined.

Let us now suppose that a parallel is to be drawn through every tenth degree of latitude; that is, through 40°, 50°, 60°, 70°. As the middle latitude exceeds 50° by 150 minutes, take 150′ from the scale of equal parts, and set it off from C to 50. Again, take 600, which are equal to 10°, from the scale of equal parts, and set off that distance from 50 to 40, from 50 to 60, and from 60 to 70. The point E, corresponding to 35°, is found by setting off 300′ from the point 40. If we were to proceed according to Flamsteed's method, as originally employed by him, it would be necessary to draw straight lines through the points E, 40, 50, &c. perpendicular to DE, and therefore parallel to each other, and to make these lines equal respectively to the portions of the parallels on the sphere which they represent; then, dividing each line on both sides of the axis into as many equal parts as are indicated by the number of meridians intended to be drawn on each side of the axis, through the extremities and corresponding points of division to trace curve lines to represent the meridians. In this case the point L would not be required. But in the modification of the method which we are now exemplifying, from the point L as a centre an arch of a circle is to be described through each of the points E, 40, 50, &c. and each of these arches of longitude is to be made equal to the arch of the parallel on the sphere which it represents. Let us then fix upon some meridian of a given number of degrees of longitude to the eastward and westward of that represented by the line DE, which is to be so drawn as to fulfil this condition. Let AB and *ab* be the meridians assumed, the former 30° to the westward, and the latter 30° to the eastward, of DE.

The arch BE or *b*E is equal in length to an arch of 30° on the parallel of latitude 35°. Now, the latter arch may be determined in geographical miles or minutes of the meridian by means of the table (page 405), showing the length of a degree of longitude for every degree of latitude in geographical miles. Thus, 30° on the parallel of 35° latitude is found equal to 1474′·5. But the arch BE is of the same length. Therefore we have BE or *b*E = 1474′·5.

We might next find the angle which the arch BE subtends at the centre L, and thus determine the points B and *b*. But it is more convenient to find the chord of the arch, which may be easily done as follows:

Put a for any arch of a circle whose radius is r. Then

$$\sin. a = a - \frac{a^3}{6r^2} \text{ nearly, if the arch is not very great.}$$

In this expression put $\frac{1}{2}a$ instead of a, and it becomes

$$\sin. \tfrac{1}{2}a = \tfrac{1}{2}a - \frac{a^3}{48r^2} \text{ nearly.}$$

Doubling both sides of this equation, and observing that $2 \sin. \frac{1}{2}a = \text{chord of } a$, we obtain

$$\text{chord of } a = a - \frac{a^3}{24r^2} \text{ nearly.}$$

For arches not exceeding 30°, this formula will give the length of the chord with sufficient exactness. Let us apply it to find the chord of the arch BE.

Here $a = 1474'\cdot5$, and $r = \text{LE} = 3687'\cdot8$

Mathematical Geography.

$$\begin{array}{rlrl}
\text{Log. } a = & 3{\cdot}168637 & \text{Log. } r = & 3{\cdot}566767 \\
 & 3 & & 2 \\
\hline
\text{Log. } a^3 = & 9{\cdot}505911 & \text{Log. } r^2 = & 7{\cdot}133534 \\
\text{Log. } 24\,r^2 = & 8{\cdot}513745 & \text{Log. } 24 = & 1{\cdot}380211 \\
\hline
\end{array}$$

$$\text{Dif. of arch and chord } 9{\cdot}8,\ 0{\cdot}992166 \quad \text{Log. } 24\,r^2 = 8{\cdot}513745$$

Hence the chord of the arch BE is 1464′·7 of the meridian. Taking this number from the scale of equal parts, and setting it off from E towards B and *b*, the points B and *b* are determined.

Proceeding in the same manner, we may find the arches of 30° of longitude, with their chords, on the other parallels of latitude; and thence determine the remaining points through which each of the projected meridians AB, *ab* passes. The curves drawn through these points will be the representations of the two meridians which have 30° of longitude to east and west of the meridian represented by DE.

The points in which the projections of the intermediate meridians intersect the projected parallels, may be found by dividing each parallel into thirty equal parts from the axis, both towards the right and left; then, by tracing curves through the proper corresponding points of division, as many meridians may be represented as are judged to be necessary. If the map is to extend farther than 30° on each side of its middle meridian, the division of the parallels may be extended to the necessary distance beyond the meridians AB and *ab*.

It is a consequence of the properties of this projection, that distances on the map may be readily and accurately measured by a scale of equal parts. This scale may be constructed as follows:

Draw a straight line AB (Plate CCLXI. fig. 8) equal to an assumed number of degrees of latitude. If we assume 35 degrees, AB will be equal to DE. From B draw an indefinite line BC, making with AB any angle. Then, since AB is equal to 35°, or to 2417 English miles nearly, take 2417 from any convenient scale of equal parts, and set that distance off from B towards C, making BD equal to 2417. From the same scale of equal parts take 100, or 200, &c. (in the present instance we shall take 500), according to the number of miles which each of the divisions of the scale is intended to represent; and with this distance in the compasses set off from B towards C the divisions B*m*, *mn*, *np*, *pq*; the remaining part *q*D, being only 417, will not again contain it. Join AD; and through the points of division *m*, *n*, *p*, *q*, draw straight lines parallel to AD, and intersecting AB. Each of the divisions of AB thus found will represent 500 miles, with the exception of that adjacent to A, which will correspond to 417 miles. The distance of two places of the map applied to this scale will give the distance in English miles.

Development of the Curve Surface of a Cylinder.

The principle of this development is analogous to that of the conical, and may be illustrated in a similar manner. Let the arch AB (Plate CCLXI. fig. 9) be a fourth part of a meridian, and draw the lines AC, BC to the centre; these lines will be at right angles to each other, so that if we suppose BC to represent the semiaxis of the sphere, then AC will be the radius of the equator. Let EF be any arch of the meridian, and let it be bisected in G. Through G draw DH perpendicular to AC, or parallel to BC. If the plane figure BDGAC be supposed to revolve round BC as an axis, the arch AB will describe one half the surface of the sphere, the line DH will describe the surface of a right cylinder, the point A will describe the equator, and the points E, F, G, will describe parallels of latitude. If EF be a small arch, the zone of the sphere which it describes will nearly coincide with the corresponding zone of the cylinder. Any tract of country delineated upon the former may, therefore, be nearly represented upon the latter; and the cylinder being developed, the meridians will be represented by parallel and equidistant straight lines, as will also the parallels of latitude; the lines representing the former being at the same time at right angles to the lines representing the latter. Let EF*fe* be a portion of the zone described by EF comprehended between two meridians of which the difference of longitude is equal to the difference of latitude of the parallels described by the points E and F. The breadth of the map representing this portion will be equal to the arch G*g* of the middle parallel of latitude. But since the difference of latitude and difference of longitude are supposed equal, the arch G*g* is the same part of the middle parallel that EF is of the meridian. Hence we have rad. : cos. mid. lat. : : EF : G*g*; so that G*g* may be found in minutes of the meridian. Upon this principle depends the construction of the plane chart, which is said to have been invented by Henry, son of John king of Portugal.

As an example, let it be required to construct a plane chart extending from 30° to 50° north latitude, and from 5° to 25° west longitude. Here the difference of latitude and difference of longitude are each equal to 20°, and the middle latitude is 40°. Hence we have EF, the length of the chart, equal to 1200′, and the breadth of it equal to 919′·25. Construct a parallelogram EF*fe* (Plate CCLXI. fig. 10), of which the sides EF, F*f* are respectively equal to 1200 and 919·25 taken from any the same scale of equal parts, which is to be considered as a scale of minutes of the meridian. Divide EF and F*f* each into four equal parts, and through the points of division draw straight lines parallel to F*f* and EF, and these lines will represent the parallels of latitude and meridians for every fifth degree of latitude and longitude. If it is required that the chart should extend to a greater number of degrees of longitude east or west, the parallels of latitude may be produced, and additional meridians drawn on the left of EF, or on the right of *ef*.

The plane chart has nothing to recommend it but its simplicity. The degree of longitude bears to the degree of latitude its proper proportion only at the middle parallel of latitude, where the sphere and the cylinder are supposed to intersect each other. Hence the rhumbs, as shown by this chart, are altogether erroneous, except when the places between which the rhumb is drawn are very near the equator.

The utter inadequacy of the plane chart to serve the purposes of navigation, induced ingenious men to turn their thoughts to the problem of constructing a chart in which the rhumbs should be straight, lines, and at the same time the bearings of places accurately represented. The first condition of the problem is satisfied in the cylindrical development which we have already explained, since in it the meridians are represented by parallel straight lines; so that the line that makes equal angles with them all must be a straight line. We are now to consider by what modification of this development the other condition may be satisfied. This can be accomplished in no other way than by preserving at every point on the map the ratio of the degree of longitude to the degree of latitude, the same as it is at the corresponding point of the globe. Let us suppose then that a cylinder is constituted on the equator as a base, and has its axis coincident with that of the globe. Let us suppose further that the globe, with its usual delineations upon it, is expanded as if it were inflated, so as to meet the cylinder, all its parts stretching in such a manner as that the meridians lengthen in the same proportion as the parallels do, until every part of its surface touches the concave surface of the cylinder; then will each parallel have the same diameter as the equator, and the meridians will

Mathematical Geography.

be straight lines parallel to each other; but from the equator towards each pole they will be gradually increased in length at each point, so as to preserve the exact proportion between the degree of the meridian and the degree of longitude on the parallel which passes through that point.

If the cylinder be now spread out on a plane surface, it will present a chart having the important properties required; the rhumbs will be represented by straight lines, and the bearings of places will be accurately shown.

Such is the principle of *Wright's*, or, as it is usually called, *Mercator's chart*. A chart of this description was first published by Gerard Mercator in the year 1556. It is not known on what principle he proceeded in constructing it; but it is certain that the true principles of the construction were unknown to him, for these were first found by Edward Wright of Caius College, in Cambridge.

It remains to inquire how the lengthened meridians are to be determined so that the chart may be constructed. This problem can be accurately resolved only by the assistance of the fluxional calculus (see Fluxions). But we may approximate to the solution by reasoning as follows:

Let AB (Plate CCLXI. fig. 11) be a quadrant of the meridian; draw AC, BC, to the centre; and let BC represent the semi-axis; then AC will be the radius of the equator; and if any point D be taken in the quadrant AB, the arch AD will be the latitude of the point D. Draw AG, CG, the tangent and secant of the arch AD, and DE, DF, its sine and cosine. The increase which the arch AD acquires in being transferred from the sphere to the cylinder is made at every individual point of the arch, so that the whole augmentation is the sum of these indefinitely small increments. Let us suppose, then, that AD is divided into a number of small portions, for example, into minutes. Since similar arches of circles are to one another as their radii, and the radius of any parallel is the cosine of the latitude of that parallel to the radius of the sphere, if we put L for any latitude, we have rad. : cos. L : : 1′ of the meridian : 1′ on the parallel whose latitude is L. But from the similar triangles GAC, CED, it is evident that CD : CE : : CG : CA; that is, for any latitude L, rad. : cos. L : : sec. L : rad. Therefore we have, sec. L : rad. : : 1′ of the merid. : 1′ on the parallel whose latitude is L; and this applies alike to every minute of which the arch AD is made up. Let us now suppose a minute on any one parallel to become equal to a minute on the equator, or to a minute of the meridian, by the parallel being brought into coincidence with the surface of the cylinder, in consequence of the expansion of the spherical surface. The minute on the meridian undergoes a corresponding increase. Let d denote it in its lengthened state; then, taking for granted that the increase on each minute of the meridian depends entirely on that of the higher of the two parallels which pass through its extremities, we obtain

$$\text{sec. L : rad. : : } d \text{ : 1′ of equator, or 1′ of meridian;}$$

$$\text{hence } d = \frac{\text{sec. L} \times \text{1′ of mer.}}{\text{rad.}}.$$

Let 1′ of the meridian be now assumed as the radius; then $d =$ sec. L to the radius 1′ of the meridian; or, since secants to different radii are proportional to one another, and we only require proportional quantities, we have simply

$$d = \text{sec. L.}$$

Thus the increased minute on the chart for each successive minute of which the arch AD on the sphere is made up, is proportional to the secant of the latitude of the higher of the two parallels which pass through the extremities of that minute. Let m denote the number of minutes in the arch AD, and take L = 1′, 2′, 3′, &c.......m' successively; and we obtain for the lengthened meridian corresponding to AD,

$$\text{sec. 1′ + sec. 2′ + sec. 3′ +, \&c....... + sec. } m'.$$

If, instead of dividing AD into minutes, we had divided it into smaller portions, the approximation would have been so much the nearer to the truth. Upon this principle a table of the lengthened meridians corresponding to every degree and minute of latitude, called a table of *meridional parts*, is calculated; and by means of such a table Mercator's chart is easily constructed. The following table shows the length of the enlarged meridian for every fifth degree of latitude:

Lat.	Merid. Parts.	Lat.	Merid. Parts.	Lat.	Merid. Parts.	Lat.	Merid. Parts.
0°	0·00	25	1549·99	50	3474·47	75	6970·34
5	300·38	30	1888·38	55	3967·97	80	8375·20
10	603·07	35	2244·29	60	4527·37	85	10764·62
15	910·46	40	2622·69	65	5178·81	90	Infinite.
20	1225·14	45	3029·94	70	5965·92		

The approximate numbers obtained in the manner now pointed out are sufficiently correct for all nautical purposes, and indeed might be carried to any degree of accuracy. From the more rigorous investigation afforded by the fluxional calculus, it is found that the enlarged meridian is proportionally equal to the logarithmic tangent of an arch found by adding to 45° half the arch of latitude reckoned from the equator. Thus, the meridional parts corresponding to 40° of latitude are equal to the logarithmic tangent of (45° + 20°) = log. tan. 65° = 33133; and the meridional parts corresponding to 50° are equal to log. tan. (45° + 25°) = log. tan. 70° = 43389. These two numbers will be found to be nearly proportional to the numbers set down in the above table as denoting the meridional parts corresponding to 40° and 50°.

To construct Mercator's chart: Draw two straight lines WE, NS (Plate CCLXI. fig. 12), cutting each other at right angles in the point C. Of these lines, WE is to represent the equator, and NS the meridian passing through the middle of the chart. From any convenient scale of equal parts set off equal parts on the equator both ways from C. These divisions are to represent degrees of longitude; and if the size of the chart will admit, each should be subdivided into minutes. Assuming the equator as a scale of minutes, set off from C towards the north and south on the middle meridian the number of minutes in the enlarged meridian, corresponding to each degree of latitude, as shown by a table of meridional parts. Draw straight lines through every fifth or every tenth degree of the equator and divided meridian, and at right angles to them. The lines at right angles to the equator will be the meridians; and those at right angles to the divided meridian, and therefore parallel to the equator, will be parallels of latitude. Any one of the meridians may be assumed as the first meridian.

To find the bearing of any one place from another, it is only necessary to draw a straight line from the one to the other, and to observe the angle which that line makes with the meridians: that angle is the bearing required, or the *course* on which a ship must be steered in sailing from ne one place to the other. Thus, if L be the Lizard oint on the chart, and M the east end of the island of adeira, draw LK parallel to NS, and the angle KLM ill be the course to be steered from the Lizard to reach adeira. The distance of the places may be found by onsidering that it is the hypotenuse of a right-angled tri-ngle of which the *proper* difference of latitude (not the eridional difference) is one side, and the course the ad-cent angle.

Plate CCLXIII. is a chart of the world according to Mer-ator's projection. The great elongation of the degrees of titude as we advance northward and southward, ren-ers this projection very defective, in as far as the figure nd the relative magnitudes of places are concerned. But his is a purpose which it was not intended to serve. It oes answer perfectly the purposes for which it was ori-inally constructed, and has supplied what before its in-ention was a desideratum in geography.

To complete a map after the circles of latitude and ngitude on the globe have been projected on the plane rface by any one of the foregoing methods which is ound most convenient, in any particular case, the various bjects within the range of the map are to be delineated n it in such a manner as to present to the eye as instruc-ve a view as possible of the tract of country represented. he methods employed to give distinctness and extent to e information conveyed, will be best learned from the ctual examination of good maps, both general and parti-ular. Various problems might be proposed to be resolved y maps; but these the intelligent student of geography ill find no difficulty, either in proposing to himself or re-olving.

Descriptive Geography being a branch of knowledge hich is continually changing by the progress of discovery nd political revolution, the latest works on the subject ill of course supersede those which have gone before. ence it has happened that the geographical works of chard, Gordon, Salmon, and Guthrie are now of little value, unless for showing, by comparison with later works, the changes which have taken place. Amongst modern works we may mention Playfair, Pinkerton, and particularly Murray's Encyclopædia of Geography (the latest), in the English language. In the French language there are General Treatises by Mentelle and Malte-Brun, of which last there is an excellent English translation. In the German language we may mention Die Erdkunde, or, Allgemeine Vergleichende Geographiė, von Carl Ritter; an elaborate and valuable, but most voluminous work, published in Berlin, of which the first volume, on Africa, appeared in 1822, and the second, third, and fourth, on Asia, at subsequent periods, down to this present year (1834). Apparently it will extend to ten or twelve volumes of 1000 or 1200 pages each, octavo.

On the general construction of maps there is a treatise by Jamieson. This is in a popular style. Full information relating to the construction of maps of every kind, and even to the details of engraving and lettering, may be found in Mémorial Topographique et Militaire. This work, in six numbers, was composed at the general depôt of war, in the time of Bonaparte, by order of the minister. Mathematical disquisitions on the construction of maps have been given by Delahire, Mém. de l'Acad. des Sciences, 1701; Euler, Acta Acad. Petropolitanæ, vol. i. of first part; Lorgna, Principi de Geografia, 1789; Cassini, Acad. des Sciences, 1745; Clairaut, idem, 1733; Lagrange, Acad. de Berlin, 1779. There is a valuable Mémoire sur la Projection des Cartes Géographiques, 1810, by Henry, given as a sequel to Mémorial Topographique. The subject is also fully treated by Puissant, in Traité de Topographie, &c. 1807. As to maps, what has been said of books will apply to them; the latest are likely to be the best. Those of Arrowsmith, Faden, Carey, Hall, and Gardiner, are deserving of full confidence.

The best globes we know are those by Carey and Gardiner. We particularly recommend the large terrestrial globe of this last artist, as the finest we have ever seen.

GEOLOGY. The rapidly progressive state of this cience has induced us to defer the consideration of it till e reach the head of MINERALOGY; under which it will e fully treated.

GEOMANCY, GEOMANTIA, a kind of divination, per-ormed by means of a number of little points or dots, ade on paper at random, and considering the various nes and figures which those points present, and thence rming a pretended judgment of futurity, and deciding any question proposed. The word is formed from the Greek γεα, or γη, *terra*, earth, and μαντεια, divination; the ancient custom being to cast little pebbles on the ground, and thence to form conjectures, instead of the points afterwards made use of. Polydore Virgil defines geomancy to be a kind of divination performed by means of clefts or chinks made in the ground, and of which he conceives the Persian Magi to have been the inventors.

GEOMETRY.

HISTORY OF THE SCIENCE.

History.

The properties of bodies may be resolved into two classes; one comprehending those which belong to all bodies whatsoever, and another, such as belong only to particular bodies. Amongst the properties of the first class we may consider extension, magnitude, figure, divisibility, impenetrability, inertia, weight, mobility, &c. Some of those of the second are solidity, liquidity, transparency, and the like. Of these properties, *extension*, *magnitude*, *figure*, and *divisibility*, are the subject of Geometry. The discussion of other properties of body belongs to Physics, called also Natural Philosophy.

The objects of geometry having been continually presented to the human mind, and being of such a nature as could at all times be perfectly comprehended, it may be supposed that the science would in some form or other exist from the very beginning of society. Indeed there is a natural geometry which all possess, and which must have been employed in the divisions of property and the erection of dwellings in every age. The name of the science indeed indicates its origin, for it is derived from γεωμετρια, the science of land-measuring.

According to the testimony of Herodotus, the science was first cultivated in Egypt. He had been informed at Memphis and Thebes, that Sesostris the king had divided the lands amongst his subjects, giving to each an allotment, for which an annual tribute was to be paid. The overflowing of the Nile, however, disturbed the landmarks, and rendered it necessary to re-adjust them by measurement; and hence the origin of geometry, which in the course of time passed from Egypt into Greece. There are two things to be here noticed; the assertion of a verification depending on geometry, and the particular opinion of Herodotus as to the origin of the science. If, as some chronologers have supposed, Sesostris be the same as the King Sesac, or Shishac, who made war on Rehoboam, the son of Solomon, it would follow from Herodotus, that geometry had its origin not more than about a thousand years before the Christian era. It might, however, be earlier; for the operation of measuring the land indicated a science which had made some progress. Aristotle has attributed the invention of geometry to the Egyptian priests, who, living secluded from the world, had leisure for study. But however this might be, all ancient writers are agreed in giving the Egyptians the credit of having been the earliest cultivators of geometry.

The philosopher Thales, who lived 640 years before Christ, brought the sciences, and particularly mathematics, into Greece from Egypt, whither he had gone in quest of knowledge at an advanced period of life. Diogenes Laertius relates that he there measured the height of the obelisks by means of their shadows; and Plutarch says, that this display of skill in geometry astonished the king Amasis. This shows that the Egyptians had not then advanced far in geometrical knowledge. Proclus also has recorded that Thales, by geometrical principles, determined the distance of vessels remote from the shore. On his return to Greece he founded the Ionian school, so called from Ionia, his native country. His celebrity for learning excited the attention of his countrymen, and drew to him disciples.

There appears to have been some slight traces of geometry in Greece at a still earlier period. We allude to the geometrical construction of a triangle by Euphorbus of Phrygia, and the discovery of some properties of figures. These, however, were probably just the natural geometry common to all ages. The rule and compasses, most important instruments, have been referred to the ages of fable, the honour of the invention of the latter having been ascribed to the nephew of Dædalus, and that of the square and level to Theodorus of Samos, one of the architects of the temple of Ephesus. But there are no certain indications of geometry as a science before Thales. He laid its foundation in Greece, and infused into his countrymen a taste for the science. He is said to have applied a circle to the measurement of angles, and to have discovered various properties of triangles, by comparing them one with another. In particular, he discovered the important proposition that all angles in a semicircle are right angles, a discovery which greatly delighted him, and for which he expressed his gratitude to the Muses by a sacrifice. Proclus has recorded that he made many discoveries in the science, which, however, have gone to the common stock of geometrical knowledge that had accumulated before Euclid collected it into a system, and the authors of which are unknown. It is probable that the greater part of the disciples of Thales were geometers, but few of their names have descended to us. Ameristus and Anaximander are the only ones now known. Of the former we only know that he was a skilful geometer. The latter wrote a kind of elementary treatise or introduction to geometry, the earliest work of the kind that is known to have existed.

Thales was succeeded in his school by Anaximander, who is said to have invented the sphere, the gnomon, and geographical charts. These required a considerable knowledge of geometrical science. It has been said that he attempted the grand practical geometrical problem of measuring the magnitude of the earth. This probably has originated in his being the inventor of representations of its surface. The honour of being the first to measure the earth seems to belong to another. Anaximander was followed by Anaximenes, born at Miletus 540 years B. C. He is said to have invented sun-dials, and thus must have known both astronomy and geometry; indeed a desire to understand the former would prove a strong stimulus to the study of the latter. He had as his disciple and successor Anaxagoras, who being persecuted for his opinions, employed himself in prison in trying to square the circle. This is the first notice on record of an attempt to resolve what appears now to be an insoluble problem, on which no modern geometer will spend his time. It might, however, have a very different aspect to the ancient mathematicians.

Pythagoras, born about 580 years B. C., was one of the greatest men of antiquity. According to some he was a Tuscan, whilst others say he was a Tyrian; but his name is better known than his origin. At the age of eighteen he became the disciple of Thales, and imbibed deeply his opinion of the importance of temperance and economy of time as necessary to success in the study of philosophy. In the infancy of science knowledge was only to be acquired by travel, the men of different countries standing in the place of our modern books as the depositories of learning. Pythagoras visited Phœnicia, Chaldea, and India. In the annals of this last country the remembrance of the philosophical traveller is still preserved. He afterwards went into Egypt, where he is said to have remained twenty-two years, holding intercourse with the priests. The long duration of his abode is not probable, as the knowledge he seems to have acquired did not correspond to so protracted a residence. Whilst

Egypt, he is said to have consulted the columns of Sothis, n which that celebrated person had inscribed the princi- les of geometry. He returned to Samos, his adopted coun- y, and there opened his school; but not finding auditors, e removed to Italy, and took up his abode in Cortona, a wn in the territory of Tarentum, where he found many isciples, and acquired a great reputation. He is said to ave discovered the important theorem in geometry, that a right-angled triangle the squares on the sides contain- g the right angle are together equal to the square on the de opposite to it; and on this account he is said to have crificed an hundred oxen in gratitude to the Muses. The crifice is probably a fable. The shedding of blood was ntrary to his moral principles, and so many oxen were t likely to be at the disposal of a philosopher. In his hool, geometry made great progress, and was augmented y several new theories, such as that of the incommensu- bility of certain lines, in particular that of the side of a uare to its diagonal. The theory of the regular solids d its origin also in the Pythagorean school, a doctrine hich requires an extensive knowledge of geometry. This bject, now neglected amidst the riches of modern ma- ematics, because of its small utility, was in the beginning great importance, on account of other discoveries which ust have been incidentally made in its prosecution. Dio- enes Laertius has attributed to Pythagoras the discovery at of all figures having the same boundary, the circle nong plane figures, and the sphere among solids, are the ost capacious. If this was so (a thing doubtful), he is the st on record who considered isoperimetrical problems.

The Pythagorean school sent forth many philosophers d mathematicians: amongst the latter, Philolaus and Ar- ytas held a distinguished rank. Of Philolaus we know t little. He held to its full extent the Pythagorean doc- ine of the motion of the earth round the sun as a centre, d was the first to unveil it. He composed a work on echanics, and thus has a claim to be associated with Eu- xus and Archytas as inventors of that part of mathema- cs. He had a tragical end, having been massacred by e people of the small republic of which he had been a gislator. We know more of Archytas. He was the au- or of a solution of the problem of two mean proportionals. e was also one of the first who made use of the geome- ical analysis, which, according to Proclus, he had learned om Plato, and by its assistance he made many discoveries geometry. We pass over his mechanical inventions, e of which, the artificial pigeon, which winged its way rough the air, certainly savours of the marvellous. Ar- ytas is said to have been blamed by Plato for applying ometry to mechanics; but if this was so, it might be for e manner of the application. His solution of the problem finding two mean proportionals gives support to this njecture; for although ingenious, it has the defect of re- iring a motion which cannot be executed.

Democritus of Abdera cultivated geometry extensively. has been conjectured that he was one of the first who eated of the contact of circles and spheres, and of irra- onal lines and solids.

Hippocrates, who lived about the year 380 B. C. was ori- nally a merchant; but having no turn for commerce, he d not prosper. To renovate his affairs, he went to Athens, d there for the first time became acquainted with geome- y, which seemed to suit his particular turn of mind. In e prosecution of this study he discovered that the curvi- neal space, called from its form a *lune*, comprehended y half the circumference of one circle and the fourth of e circumference of another (their concavities being turned e same way), was equal to a rectilineal space, viz. the ea of a right-angled triangle, whose hypothenuse was the ameter of the circle, and its sides each equal to the ra- us of the quadrantal arc. This could not be considered as a true quadrature of a curvilineal space; it was merely a geometrical juggle, by which a common space being taken from two equal curvilineal figures, one of the remainders was by a sort of chance a rectilineal figure. The first true quadrature of a curvilineal space is due to Archimedes. Hippocrates attempted the quadrature of the circle; but, if his mode of reasoning has been truly handed down to us, he committed a great oversight. This is the first recorded paralogism in geometry. He was more successful in treating of the duplication of the cube, which he showed to depend on the finding of two mean proportionals between two given lines. He was also the first who composed elements of geometry, but these have been lost. He appears to have retained the mercantile spirit, insomuch that he accepted money for teaching geometry. On this account he was expelled the Pythagorean school; a measure somewhat hard, considering his reduced circumstances.

Two geometers, Bryson and Antiphon, appear to have lived about the time of Hippocrates, and a little before Aristotle. They are only known by some animadversions of the latter on their attempts to square the circle. Before this time geometers knew that the area of a circle was equal to a triangle whose base is equal to its circumference, and altitude equal to its radius. This truth could not escape the observation of the early geometers. Bryson erroneously believed that, by a geometrical construction, he could find the circumference, in which case the quadrature would have been easy. Antiphon, it appears, proceeded by increasing continually the number of sides of an inscribed regular polygon, and considered the circle to be equal to the ultimate result; a process perfectly correct, and the same in effect as that by which Archimedes found the area of the parabola.

From this brief view of the progress of geometry during the first two centuries after its introduction into Greece, we pass to the school of Plato, in which geometry completely changed its character, and advanced with increased vigour and more rapid strides. Hitherto its subjects had been of the most elementary nature; now, however, the views of geometers became more enlarged, and a new era in the science commenced. Although the disciple and successor of Socrates, who had no taste either for mathematical or physical science, Plato held them in the highest estimation; and, imitating the earlier sages of Greece, he undertook voyages and journeys to improve his mathematical knowledge. He visited Egypt to converse with the priests, and Italy to consult with the celebrated Pythagoreans Philolaus, Timæus of Locris, and Archytas. With the last of these he contracted a particular friendship. He went also to Cyrene to hear the discourses of the mathematician Theodorus; and on his return to Greece, when he had founded his school, he made the mathematics, particularly geometry, the basis of his instructions; and his disciples, encouraged by his example and his exhortations, applied with ardour to the study of that science. He never allowed a day to pass without making his disciples acquainted with some new truth. He placed over his school this inscription, *Let no one ignorant of geometry enter here.* He held that the Divinity continually geometrizes; meaning thereby, no doubt, that the laws by which the universe are governed are in accordance with the doctrines of mathematics. It does not appear that Plato composed any work expressly on the mathematics; but his invention of the geometrical analysis may be considered as one of the greatest improvements the science has received. The theory of Conic Sections originated in the Platonic school; and a third discovery was that of Geometrical Loci, a theory not only beautiful and interesting on account of the abstract truths which it unfolds, but also by reason of its great importance in the resolution of geometrical problems. The celebrated problem concerning the duplication of the cube was agitated about his time; but its origin was earlier; for Hippocrates, as has been already stated, had reduced it to the finding of two continued mean proportionals. Plato himself gave a solution of the problem; and it was also resolved by Archytas, Eudoxus, Eratosthenes, and Menæchmus. The solutions of eleven of the ancient geometers have been preserved in the Commentary of Eutocius on Archimedes' Treatise concerning the Sphere and Cylinder. It is probable that the trisection of an angle, a problem of the same degree of difficulty as the duplication of the cube, excited the efforts of the Platonic school. We have indeed no positive testimony in favour of this conjecture; but the progress of the human mind does not allow us to doubt that the problem was of great antiquity. After the solution of the very simple problem, the bisection of an angle, it was natural to think of dividing it into three equal angles; and those who first thought of the latter problem would no doubt be astonished to find, that two problems so like in appearance should yet differ so much in the difficulty of their solution. The trisection of an angle, and the duplication of a cube, are in fact problems of such a nature that they cannot be resolved by straight lines and circles alone, the only lines admitted by the ancients into their elements of geometry. The reason of this impossibility would not be apparent to the ancient geometers, although it is made evident by the modern doctrines of algebra.

The names of the individuals to whom we owe the particular discoveries which have been specified have not come down to us; they must therefore be regarded as belonging to the Platonic school generally. Proclus has recorded the names of a number of the geometers of that school. Some of advanced years attended it as friends of its celebrated head, or from respect to his doctrines; others, chiefly young persons, as disciples. Of the first class were Laodamus, Archytas, and Theætetus: Laodamus was one of the earliest to whom Plato communicated his method of analysis before he made it public, and he is said to have profited much by the possession of this instrument of discovery. Archytas was a Pythagorean, having extensive knowledge in geometry and mechanics. He frequently visited Plato at Athens; but in one of his voyages he perished by shipwreck. Theætetus was a rich citizen of Athens, who had studied along with Plato under Socrates. He appears to have cultivated the theory of the regular solids, called now the Platonic bodies.

The progress of geometry now required that its elements should be new modelled. This was done by Leon, a scholar of Neoclis, or Neoclides, a philosopher who had studied under Plato. To Leon has been ascribed that part of the solution of a problem called its *determination,* which treats of the cases in which the problem is possible, and of those in which it cannot be resolved. Eudoxus of Cnidus was one of the friends and contemporaries of Plato; he generalized many theorems, and thereby greatly advanced geometry. It is believed that he cultivated the conic sections; and even the invention of these has been ascribed to him. He resolved the problem of the duplication of the cube; and it is to be regretted that Eutocius, who speaks with contempt of his solution, has not recorded it with others in his Commentary on Archimedes. Diogenes Laertius has attributed to him the invention of curve lines in general; from which we may infer, that other curves besides the conic sections were known in the school of Plato. Archimedes, in his Treatise on the Sphere and Cylinder, says that Eudoxus found the measure of the pyramid and cone, and that he was especially occupied with the contemplation of solids. Some have given him the credit of being the writer of the fifth book of Euclid, which treats of proportion. Amongst the numerous mathematicians of the Platonic school, there was one, Cratistus, who is particularly mentioned by Proclus. He was a remarkable person; for his knowledge of his science was in a manner innate. There was no problem of that time, however difficult, which he could not resolve by his natural geometry. He was the Pascal of antiquity. There were two brothers, Menæchmus and Dinostratus, who also greatly distinguished themselves. The former, a particular disciple of Plato, extended the theory of the conic sections. Eratosthenes seems to attribute to him the merit of having invented them; at any rate, he was the first who solved the problem of doubling a cube by means of these curves. Dinostratus followed in the path of his brother, and advanced geometry by his discoveries. He is particularly known as the reputed inventor of a curve called the *quadratrix,* by which he seems to have intended to divide an angle or an arc of a circle in any given ratio. The curve takes its name from a property by which, could it be constructed geometrically, the quadrature of the circle would be obtained. According to Pappus, Dinostratus discovered this property of the curve; and probably this is the reason why it has been called the quadratrix of Dinostratus, just as we say the spiral of Archimedes. Indeed there is some ground for believing that the curve was invented by Hippias, a philosopher and skilful geometer, contemporary with Socrates.

It was chiefly in geometry that the followers of Plato excelled. In this they imitated their leader, who directed his attention to abstract speculations, rather than to the study of nature. The conic sections, one of their most refined and profound geometrical theories, remained merely an intellectual speculation from its first invention till the days of Kepler and Newton, when it acquired a high importance on account of the discovery that the orbits of the planets are conic sections.

The school of Plato, after the death of its founder, was divided into two others, which, although opposed to each other on various points, yet agreed in holding the mathematics in esteem, and in regarding them as an indispensable preparation for the study of philosophy. It is recorded, that a person ignorant of geometry and arithmetic having presented himself for admission into the school of Xenocrates, the successor of Plato after Speusippus, he was repelled by its chief, with an intimation that he was not properly prepared for the study of philosophy: *Ansas philosophorum non habes,* said the philosopher.

The mathematics, thus encouraged and protected, continued to be cultivated and improved. The celebrated geometer Euclid was of this school; and it may be conjectured, from the age in which he lived, that he had acquired his knowledge under the tuition of the first successors of Plato. So also, we may presume, was Aristæus, another celebrated geometer of antiquity, though little known in our time, because his works have perished. We learn, however, from Pappus, that he was one of the ancients who contributed the most to the progress of the sublime geometry. He was the author of two excellent works; one a treatise on *The Conic Sections,* in five books, which contained a great part of what Apollonius has given in the first four books of his work; the other, also in five books, treated of *Solid Loci.* Pappus, in prescribing a course of study to his son, places this last work next in order after the Conics of Apollonius. Hence we may infer that the propositions which it contained were of a higher order of difficulty, and required a previous knowledge of the conic sections. Euclid entertained great esteem for Aristæus. We may hence conclude that he was either his disciple or his intimate friend.

The pure mathematics were less cultivated in the school of Aristotle than they had been in that of Plato; they were not, however, neglected; for, unlike the modern peripatics, who discouraged the study of geometry, Aristotle as deeply versed in the science, as may be inferred om his writings, which abound in examples drawn from ometry.

Although the mathematics received but little addition the Aristotelian school, still they had some cultivators. f these, Theophrastus was the principal. He wrote some eatises relating to them, particularly a complete history these sciences down to his time, a work which has un- tunately been lost. It consisted of four books on the story of geometry, six on that of astronomy, and one that of arithmetic. We have great reason to regret e want of the sure light which this work, had it come wn to our times, would have thrown on the origin and ogress of these sciences, instead of which, we have only a v glimmerings, that serve to make the darkness sen- le, but not to dissipate the obscurity. Another dis- le of Aristotle, Eudemus, composed a history of the thematics. This consisted of six books on the history geometry, and as many on that of astronomy. We e to these all we now know concerning the origin of ose sciences; for it is from this source that Proclus, heon, and Diogenes Laertius have drawn the few notices hich they have transmitted to us.

We come next to a new epoch in the history of the an- nt mathematics. This was the institution of the school Alexandria. However memorable this event may have en in the history of general literature, it is more espe- lly remarkable in that of the mathematics; for in this ebrated school all the mathematical sciences were cul- ated with a degree of care not inferior to that which d been bestowed on pure geometry in the school of ato, and with corresponding success.

The period which immediately followed the death of exander proved one of trouble and confusion. The vast pire founded by that conqueror was dismembered by principal captains; and Egypt was the portion which to one of them, Ptolemy Lagus. As soon as he had ablished tranquillity in his dominions, Lagus turned his ention to the sciences; and by his encouragement of ir cultivators, he drew to him many of the learned of eece; and his capital soon rivalled Athens as the resort men of knowledge and talent. These constituted the exandrian school. The perfection of this celebrated ablishment is mainly due to his son and successor Pto- ny Philadelphus, who bestowed on the learned men he induced to settle in his capital, protection and liberal couragement. Amongst those who resorted to this in- ution, none has been more celebrated than the Greek ometer Euclid. His country is unknown; and of the nts of his life no notice has reached us. It appears that had resided in Greece, and studied geometry under disciples of Plato. Thence he went to Alexandria, uced probably by the liberality of the first Ptolemy. ppus has described him as gentle and modest, and en- taining a particular regard for those who could contri- e to the progress of the mathematics. His character med a contrast to that of Apollonius, another geo- ter, who was vain, and delighted in depreciating his temporaries. We may suppose that Euclid was not ch of a courtier, from his reply to Ptolemy, who in- red of him whether there was not an easier way to a owledge of geometry than the study of his Elements. here is no royal road to geometry," was his answer. have elsewhere (see Euclid) given a full account of s distinguished geometer and his writings.

he great excellence of the Elements of Euclid must rease our regret for the loss of a treatise which he com- ed on *Porisms*. Of this work, all that has come down modern times is an abstract, inserted by Pappus Alex- lrinus in his Mathematical Collections. This, however, has suffered so much from time, that all we can immediately learn from it is, that the ancients put a high value on porisms, and regarded them as an important part of their analysis. The efforts of modern geometers had been exerted in endeavouring to discover the nature of porisms, but without much success. At length Dr Robert Simson, with a zeal and perseverance not to be surpassed, succeeded in divining their nature, and even in restoring a great number of Euclid's propositions. These form a part of the posthumous works of this distinguished geometer.

Leaving the Alexandrian school, our attention is drawn to Sicily, which gave birth to Archimedes, a geometer whose genius has been the admiration of all who have come after him. His life was written by Heraclides; but this precious piece of biography, so well calculated to interest our curiosity, has unfortunately perished. Archimedes was born 287 years before our era. He was the relation and friend of Hiero, king of Syracuse. His skill as a mechanician is universally known; but it is only as a geometer that we shall speak of him here. Endowed with a mind of the highest order, he exerted it in the extension of mathematical science. The measure of curvilineal magnitude was a subject new in his time, concerning which but little was known. Archimedes attached himself to this branch by predilection, and opened new views, which have engaged the attention and exercised the genius of such men in modern times as Kepler, Cavalieri, and Dr Wallis. The last of these has called him a man of prodigious sagacity, who first laid the foundations of almost all that had given celebrity to the seventeenth century of our era.

The writings of Archimedes were numerous. We have two books by him on the sphere and cylinder, which terminate in the fine geometrical discoveries, that the solidity and surface of the sphere are respectively two thirds of the solidity and surface of the circumscribing cylinder, with which he was so much delighted, that he desired that these figures should be inscribed on his tomb. His book on the measure of the circle is a kind of supplement to his treatise on the sphere, which supposed a knowledge of that measure. The determination of the exact ratio of the diameter to the circumference was, as at present, a problem not to be resolved; but he found limits to that ratio, and an approximation to it sufficiently accurate for the ordinary wants of the arts, which was all that he attempted. He might, however, have carried his approximation farther, as was afterwards done by Apollonius, and by Philo, another geometer less known.

Archimedes having succeeded in measuring the sphere and cylinder, bodies long the study of geometers, he opened a new field of inquiry in his Treatise on Conoids and Spheroids. All his determinations are now familiar to geometers; his processes of reasoning are highly ingenious, but withal somewhat intricate. Indeed we question whether many modern mathematicians have had patience to go through his investigations, considering that the same conclusions can now be reached by much shorter methods.

The properties of the spiral, invented by his friend Conon, and the quadrature of the parabola, are among the additions made to the ancient geometry by Archimedes. This last was a grand step in the progress of geometry; because it was the first curvilineal space legitimately squared, and the only one, until the application of the modern methods of analysis. In latter times the notion of infinity has been introduced into geometry, and has contributed greatly to its extension. The ancients, however, carefully avoided this term, which might have injured the stability of the science. Their theory of exhaustions supplied its place, and was a safe, although a laborious and indirect way of establishing truth. The writings of Archimedes give the finest examples of its application. We pass over the mechanical and optical inventions of this great man, and only observe that they indicate a state of considerable perfection in the geometrical science of that period.

The writings of Archimedes are the most important of the few classic remains of ancient geometry which we now possess. The subjects of which they treat, being less elementary, are now less studied than those in the Elements of Euclid. Every geometer, however, should have read them at least once in his life. The earliest edition of his writings was published at Basle in 1644. It was in Greek, with a Latin translation by Venatorius, the two versions being printed as separate volumes, and accompanied by the Commentary of Eutocius. There have been many editions of his works. Of these we shall only notice two; that of Torelli, in Greek and Latin, published at Oxford in 1792, and a French translation of his writings by Peyrard, the learned editor and translator of Euclid's works.

Returning to the school of Alexandria, we have to mention Eratosthenes, a geometer as well as an astronomer. Indeed he was one of those uncommon men, whose genius embraces all subjects; for he was also an orator, a poet, an antiquary, and a philosopher. His extensive knowledge induced the third Ptolemy to make him his librarian. He chiefly cultivated geometry and astronomy, and has been classed with the three great geometers of antiquity, Aristæus, Euclid, and Apollonius, who had improved geometrical analysis. Pappus mentions a work by Eratosthenes on this subject, in two books. He has told us its title, but has not described its exact object, which can therefore only be conjectured. He gave a solution of the problem of the duplication of the cube, which Eutocius has preserved in his Commentaries on Archimedes; and he applied his geometrical and astronomical science to the solution of the grand problem, the measurement of the magnitude of the earth, which, however, had been attempted before his time.

Apollonius of Perga appeared as a geometer in the Alexandrian school, about the time when Archimedes had finished his career. It might be a question which of these two great men was endowed with the higher genius; for such was the estimation in which Apollonius was held at the period in which he lived, that he obtained the appellation of the *great geometer*. He was the most profound and fertile writer that has ever treated of geometry. His works which have survived the ravages of time, or have been restored by modern geometers, with the addition of the Data and Porisms of Euclid, this last also a restoration, constitute nearly all which we now know of that beautiful subject, the ancient geometrical analysis. Whoever would understand it, and acquire skill and facility in its application, would do well to study with care the various works of Apollonius which have been restored, if not exactly according to the letter, at least in the true spirit of the originals. A full account of the writings of this distinguished geometer has been given as an article of biography (see APOLLONIUS); it is therefore unnecessary to enumerate them here.

The ancient mathematicians addressed their writings to others, their particular friends. It is in this way that the names of some of their contemporaries have descended to us, although their writings have been lost. Apollonius dedicated the first three books of his Conics to Eudemus, a geometer, and in such terms as show that he addressed himself to one well acquainted with the subject. He says that he had been encouraged to study the subject by Naucrates; and he requests Eudemus to communicate what he had written to Philonides, also a geometer. Eudemus having died, he addressed the fourth book to Attalus, and speaks of Thrasydeus, with whom Conon of Samos, a little anterior to his time, had held a correspondence on the conics; also of Nicoteles the Cyrenean, who it seems had a controversy with Conon. The regret which Archimedes expresses for the loss of Conon gives us reason to believe that he was a profound geometer. We know also that he was an astronomer. Archimedes dedicated several of his works to Dositheus, another geometer, whose name has thus become known to us.

It was about this period that the geometer Nicomedes lived. He was the inventor of the *Conchoid*, a curve which served to resolve two remarkable problems, the duplication of the cube, and the trisection of an angle.

The period which comprehended the ages of Euclid, Archimedes, and Apollonius, was that in which the science of geometry shone forth with the greatest splendour. It had been in a state of gradual improvement from the time of Thales. Now, however, it seems to have arrived at a degree of perfection beyond which its cultivators did not carry it. We may suppose that the science of astronomy took its place, and presented a new and more inviting field of discovery. Hipparchus, the father of astronomy, was also a geometer; for we find him applying its principles, combined with arithmetic, to his science.

There were geometers who were also mechanicians. These, as well as the astronomers, probably cultivated geometry alone as connected with their own science. Gemimus of Rhodes lived between the time of Hipparchus and the beginning of our era. He was the author of a work on geometry, and another on astronomy. The former, which is lost, was probably a historical commentary, a sort of development of geometrical discoveries. Proclus seems to have drawn from it all that he has said on the history and metaphysics of geometry. Its loss is matter of regret. Ctesibius, and Hero his disciple, were celebrated as mechanicians. The former lived in the middle of the second century before Christ. Philo of Byzantium was also a celebrated mechanician. Possidonius was at once geometer, astronomer, mechanician, and geographer. He deserved well of geometry, for having repelled the attack of Zeno the Epicurean, who had attempted to invalidate its principles and certainty. Dionysiodorus was a skilful geometer, as appears by his solution of a difficult problem of Archimedes. Theodosius was the author of a work on the geometry of the sphere, which has descended to our times. It appears to have been studied as a classic in the English universities. Dr Barrow gave an edition of it, along with the writings of Archimedes, and the four books of the Conics of Apollonius, in 1615. The best edition is that of Hunt, printed at Oxford 1707.

The study of the mathematical sciences, which languished in the first century of the Christian era, revived a little in the beginning of the second. Menelaus, an astronomer, wrote on trigonometry and spherical geometry. This work has reached our times by a translation from the Arabic. Dr Halley, holding in high esteem every vestige of the ancient geometry, had prepared a new edition of this geometer, corrected from a Hebrew manuscript. It did not appear, however, until 1758, by the care of Costard, the author of a history of astronomy. Menelaus, as we learn from Pappus, cultivated the theory of curve lines; a subject which may be regarded as belonging to the higher geometry among the ancients.

Ptolemy, if not an inventive geometer, must at least have been perfectly acquainted with its theories, for he had the merit of applying them to astronomy. His Almagest has handed down from antiquity a beautiful geometrical theorem, the foundation of the Greek trigonometry. It is this; the rectangle contained in the diagonals of a quadrilateral inscribed in a circle, is equal to both the rectangles contained by the opposite sides.

Several mathematicians of no great note lived in the ird and fourth centuries of the Christian era. Such were erenus, who wrote two books on cones and cylinders; ypsicles of Alexandria, the supposed author of two books regular solids, sometimes ascribed to Euclid; and Per- us Citticus, who wrote on certain lines called *Spiriques*, rmed from a solid generated by an arc of a circle revolv- g about a fixed axis. Philo of Thyaneus, and Demetrius Alexandria, both wrote on curve lines.

We are now come to a period in which the sciences had gun to decline; when, instead of original treatises, wri- s were content to compose commentaries and annota- ns on the works of their more illustrious predecessors. was in this way that Pappus and Theon of Alexandria, o lived towards the end of the fourth century, rendered vice to the mathematical sciences. The first, however, ist not be classed with the ordinary scholiasts; for in his thematical Collections he has shown that he was an ex- t geometer. His object in composing this work was to lect into one body many scattered discoveries, and to strate and supply deficiencies in the writings of the cele- ated mathematicians who had preceded him. He has ne this in regard to Apollonius, Archimedes, Euclid, and eodosius, by a number of lemmas and important propo- ons which they had assumed as known. His writings ve made us acquainted with the various attempts made the ancients to double the cube, and to divide an angle o three or more equal parts. We are indebted to him almost all we know of these and other important mat- s in the ancient geometry; and it is through his writings t the names of many geometers have come down to our ys, which, but for him, would have been lost in the ob- rity of time. The preface to his seventh book is of in- imable value, inasmuch as it has preserved from oblivion ny of the analytic works of the ancients. His brief ana- is of these works, for that is all we have, has given con- uity to the history of geometry; and his indications have ved as vestiges of the steps by which the ancients pro- eded in their discoveries. Guided by these brief notices, ingenuity of the moderns has succeeded in restoring writings of Apollonius and Euclid, which had disap- red for ages. It is not improbable, that in this renovated m, the works of these geometers surpass in excellence originals. The restorers have had the advantage of an proved state of the science, and the works of later geo- ters, to assist them in their researches.

It is probable that at this time there is not an entire by of the eight books of Pappus in existence; certainly re is none in Britain. In a catalogue of the manuscripts England and Ireland, published at Oxford in 1698, there mention made of two copies in the Savilian library. ese have been more than two centuries in Oxford. One, rked No. 3, is in folio, and is well written on paper; it tains the Greek text of the third, fourth, fifth, sixth, venth, and eighth books, and in addition some works of eodosius and Autolycus. There is no memorial to in- ate when it was written, or by whom. The other copy, h a mark No. 9, is not so well written; it has been co- d by various hands, on separate sheets of paper. This y, besides the books preserved in the former, contains o a part of the second book. Dr Wallis has spoken of ee manuscripts of Pappus at Oxford, one in the Bodleian d two in the Savilian library. No traces of a third copy n now be found in the Bodleian library. The late Dr ail, in his life of Dr Robert Simson, has described a manu- ipt now in the Advocates' Library, Edinburgh. It con- ns five books of Pappus, viz. the third, fourth, fifth, sixth, d eighth; but unfortunately the seventh, the most valu- le portion of the work, is wanting. This was purchased Paris by Dr James Moore in 1748.

The British Museum possesses a manuscript copy of Pappus, which had been the property of the Saliante family at Verona. None of the manuscripts of which we have any details are of a very early date. There are some points of resemblance in all that have been examined, which seem to indicate a common origin. It is well known that early manuscripts are few in number; sometimes only one is known. This may have been the case in regard to the text of Pappus, and will account for the agreement of all the manuscripts in particular places. We owe the edition which we possess of this ancient work to the labour of Commandine, who translated and enriched it with notes, but died when he was about to give it to the world. It afterwards appeared in 1588, under the patronage and by the pecuniary aid of Francisco Maria, duke of Urban. That part of the second book which has been preserved was published in the third volume of the works of Dr Wallis: it treats of the ancient arithmetic.

We had formerly occasion to mention Hypatia, the daughter of Theon, as a commentator on Diophantus, in our account of the progress of Algebra. She has a claim to our notice also in the history of geometry, by her having composed a commentary on the writings of Apollonius.

The philosopher Proclus, the chief of the Platonic school at Athens, made it in some measure the seat of the mathematical sciences about the middle of the fifth century. In imitation of the chief of his sect, he held the sciences in great estimation. He was not, however, distinguished for original discoveries; but his commentary on the first book of Euclid, setting aside the fault of its prolixity, is valuable, because of the information it contains on the history and metaphysics of geometry at a remote period.

We pass over several geometers of this period, of whom hardly any thing but their names is known. We mention, however, Diocles as the inventor of a curve called the cissoid, contrived for the solution of the celebrated problem, to find two mean proportionals.

Geometrical science had by this time been long on the decline. The Alexandrian school, however, still existed; and a repetition of such a period as that in which Apollonius and Euclid flourished might have been hoped for, had it not been for the troubles which agitated the East. The taking of Alexandria by the Saracens in the year 640 gave a deathblow to the sciences, not only in that celebrated city, but throughout the Greek empire. The library was delivered over to destruction by the command of the ignorant fanatic Omar; and this, the finest monument of human genius, the accumulated store of knowledge that had been collecting for ages, was employed during six months in warming the four thousand baths of Alexandria. Such was the end of the Alexandrian school, which had for nearly ten centuries contributed to the advancement of the human mind in knowledge.

About the eighth century we find Hero, called *the younger*, an engineer and mathematician. He wrote a treatise on *Geodæsia* (so practical geometry was called), which had no great merit; it is, however, remarkable for containing, without demonstration, a rule for finding the area of a triangle when its three sides are known. There is no notice of this important theorem in the writings of the ancients which have come down to us. It was, however, probably found by some geometer earlier than Hero. It appears to have been afterwards lost, and rediscovered by Tartalca.

We have an unfavourable opinion of the modern Arabians, but there was a period when they had a very different character. When the sciences were neglected by the Greeks, and existed only in manuscripts buried in the dust of libraries, the Arabians brought them forth from obscurity, and gave them an honourable asylum. They were the depositaries of knowledge during the ages of barbarism and ignorance which overspread Europe; and we owe to our intercourse with them the first glimpses of light which penetrated the obscurity of the eleventh, twelfth, and thirteenth centuries. The Arabians diligently cultivated the science of astronomy; and as a corresponding knowledge of other branches of science was necessary to success, they became geometers, opticians, and even algebraists. The greater part of the Greek geometers, particularly those necessary to the study of astronomy, as Euclid, Theodosius, Hypsicles, Menelaus, were translated into the Arabic language in the time of Almamon, or soon after him. They even began to cultivate the sublime geometry of the ancients, for the four first books of the Conics of Apollonius were translated by order of that prince. They added to their literature the writings of Archimedes, and at least three of the last books of the Conics of Apollonius; and all these works are to be found in libraries rich in oriental manuscripts. It is from the last-mentioned work, corrected and augmented by the notes of Nassireddin, a Persian geometer, that Dr Halley has enriched our geometry with the fifth, sixth, and seventh books of the ancient Greek author; the remaining books, viz. the eighth, appear however to have been entirely lost. The Arabian writers quote the writings of several Greek geometers of which we know nothing, such as a treatise on parallel lines, another on triangles, and a third on the division of the circle. We must allow to the Arabians the merit of having given to our trigonometry its present form. They also simplified the practice of its operations, by employing the sines of the arcs instead of the chords of the double arcs employed by the Greeks. This was even one of their earliest inventions, for we find it in the writings of their astronomer Albatenius.

The Arabian historians have recorded the names of several of their cultivators of geometry; but these may be passed over, ignorant as we are of their contributions to the science. The optician Alhazen however deserves notice, because of the knowledge of geometry shown in his writings, and also on account of a geometrical problem applicable to optics which bears his name. The solution he gives was probably derived from the Greek geometers. It must be confessed the Arabians do not appear to have been an inventive people; almost always commentators or compilers, they seldom rose higher than the labours which such functions impose.

The Persians have also had their geometers. The most celebrated was Nassir-Eddin Al-Tussi. The science is indebted to him for some good works, particularly a learned commentary on Euclid, which was written in Arabic, and printed in 1590 in Italy. Another geometrical work is a revision of the Conics of Apollonius, with a commentary. Dr Halley found this useful in remodelling the fifth, sixth, and seventh books of that precious treatise. The Persian geometers have long known the principal Greek writers; and they even profess to have some of their writings which we have not known. It appears that their geometers had a peculiar taste in treating the doctrines of abstract science, for they have given every proposition of the elements a name expressive of one of its uses, or of some fanciful analogy it may have to things foreign to geometry. The forty-seventh of the first book of Euclid, for example, they call the *figure of the bride*, and the forty-eighth the *bride's sister*; and, with some reason, they call the mathematics the *difficult science*. Mathematical knowledge among the Turks has been nearly in the same state as among the Persians. The libraries of Constantinople contain Arabic and some Turkish translations of the Greek writers. Geometry is taught in their schools, but it does not appear that they go beyond the Elements of Euclid. There are hardly any traces of geometry amongst the Hebrews. We know that when Solomon's temple was built, Hiram king of Tyre furnished architects and navigators. From this we may infer that the Jews had no geometry at that period. It was not before their second dispersion that they took an interest in the sciences. However, when mixed with other nations, some of their learned men cultivated geometry, but never proceeded beyond the elements. About the time of Almamon, in imitation of the Arabians, they translated the writings of some of the Greek mathematicians into their language, in particular those of Euclid and Archimedes. They however made no addition themselves to geometrical science.

The researches of Europeans concerning the mathematical and astronomical science of India have discovered among the Hindus some works on geometry of great antiquity. We have already given some account of these interesting writings in our sketch of the history of Algebra; and we have there described the *Lilavati*, a work on arithmetic and geometry by Bhascara Acharya, a Hindu mathematician, who lived about the year 1150 of the Christian era. In another work, reputed more ancient, viz. the Surya Siddhanta, we find a rational system of trigonometry combined with fable and absurdity. There has been great difference of opinion as to the time when this last treatise, the most ancient on the Indian astronomy, was written. The French astronomer Bailly believed it to have been composed more than 3000 years before the Christian era; but more sober inquirers have judged it to be about 750 years old. The trigonometry it contains is probably much older. The Hindu books on geometry are remarkable for not containing demonstrations. The writers knew the celebrated proposition concerning the squares on the sides of a right-angled triangle, the discovery of which is ascribed to Pythagoras; and they also knew the rule for finding the area of a triangle from its sides, which was not known to the early Greeks. It appears from the Institutes of Akbar, that the Indians supposed the diameter of a circle to be to its circumference as 1250 to 3927; which is the proportion of 1 to 3·1416, and is more accurate than the determination of Archimedes, or indeed than any known before the sixteenth century.

The Chinese have cultivated astronomy from a remote antiquity, yet it does not appear that they have made any progress in geometry. They knew the proposition of Pythagoras, it would seem, earlier than it was known to the Greeks, yet it remained sterile in their hands. They had no spherical trigonometry before the thirteenth century, and then it was not of native growth; it was probably derived from the Arabians or Persians.

The Romans, unlike the Greeks, gave little attention to the sciences. The mathematics in particular were disregarded at Rome; and geometry, scarcely known there, did not extend beyond the art of measuring land and of fixing boundaries. The mathematics were, however, not unknown to Cicero. The respect with which he speaks of them, and the veneration he manifested for the memory of Archimedes in searching for his tomb, on which he knew were inscribed a sphere and cylinder, indicate that he had given some attention to the subject of geometry.

The Roman geographer Strabo must be numbered amongst the geometers of his day: and Cicero mentions another, Didymus, who was blind; but he was a Greek by birth. Vitruvius has given much information, in his architecture, on matters connected with geometry.

We pass over those ages in which the sciences had nearly disappeared in Europe, and hail with satisfaction their revival in the eighth century. Mathematical science was at first dimly recognised, like the dawn of a new day after a gloomy night, in the writings of Boethius, Bede, his disciple Alcuin, and Gerbert, who travelled into Arabia, the only country where a knowledge of the mathematical sciences could be acquired. In this he was imitated by the English monk Adelard, or Athelard, in the twelfth century, who went into Spain and Egypt; also by other

Englishmen, such as Daniel Morlay, Robert of Reading, William Shell or William de Conchis, Clement Langton, &c. Adelard on his return translated Euclid, and he appears to have been the first who made this writer known in the West. His work was never printed. Plato of Tivoli translated the Spherics of Theodosius into Latin about 1120; but this translation was not printed before 1518. It is worthy of remark, that almost all the restorers of the sciences were ecclesiastics, who in the seclusion of the cloisters studied the works of the ancients which had been preserved in the monasteries. This at least is one benefit the world has received from the leisure of the monks of that period, which all of them did not spend in idleness.

The sciences found many cultivators, and much encouragement from sovereigns, in the thirteenth century; Jordanus Nemorarius, who lived about 1230, was well versed in geometry and arithmetic. John of Halifax, known also by the name of Sacro-Bosco, his contemporary, was a mathematician. Campanus of Navarre, the celebrated translator and commentator of Euclid's Elements, was of this age. Almost all the early editions of this work were made from his version and his manuscript commentary. We have a treatise by him on the Quadrature of the Circle. But he deviates from geometrical accuracy, by mistaking the approximate ratio found by Archimedes for the true and exact ratio. The paralogism which he gives for a demonstration may, however, be excused in the geometers of his time. They were few, and their writings must not be too nicely scanned. The name of Roger Bacon is so identified with the progress of science, that we must reckon him among the geometers of his day. In support of this claim we record his treatise on Perspective, a geometrical theory.

Leonardus of Pisa, who in the fifteenth century brought algebra into Italy, was also known as a cultivator of geometry. He composed a treatise on the subject, which Commandine thought worthy of publication, and had prepared it for the press; but his death prevented its appearance.

In the beginning of this century, Cardinal Cusa acquired reputation in geometry, by a pretended quadrature of the circle, and other writings. These, however, were only a tissue of paralogisms. It appears from the introduction to a tract of this writer, that Pope Nicolas V. who occupied the pontifical throne from 1447 to 1455, was a geometer, and had translated the works of Archimedes from Greek into Latin. The true restorers of mathematical science in the fifteenth century were Purbach and Regiomontanus. Purbach banished the use of sexagenary calculation from trigonometry, which he enriched with several new propositions. He supposed the radius divided into 600,000 parts, instead of the divisions used by the ancients; and in place of the chords of the double arcs, expressed in sexagenary parts of the radius, he calculated the sines in 600,000ths of the radius. He was the inventor of the geometrical square, an instrument used in practical geometry; and he appears to have been the first who applied the plumb-line to mark the divisions of an instrument. Regiomontanus, whose true name was John Muller (called also *John of Mont-Royal*), was born in 1436. At the age of fourteen he was captivated with the mathematical sciences, and put himself under the guidance of Purbach. The preceptor and his pupil made a journey into Italy to study Greek, in order that they might draw their knowledge from the pure sources of antiquity. Purbach died there, but his disciple followed out his purpose. He afterwards translated the Spherics of Menelaus and Theodosius into Latin; he corrected from the Greek text the ancient version of Archimedes made by Gerard of Cremona; he translated the Conics of Apollonius, and the Cylindrics of Serenus, besides other works on mixed mathematics; he commented on the books of Archimedes, which Eutocius had not touched. He defended Euclid against the imputations of Campanus, and he confuted the pretended quadrature of Cardinal Cusa. We pass over for the present his improvements in trigonometry.

Lucas Paciolus, or Lucas de Burgo, the author of the earliest printed book on algebra, contributed by the same work to the establishment of geometry. It was first printed in 1494, and was therefore one of the early printed books on the science, but not the earliest, for the first edition of Euclid was in 1482.

The decline of the Greek empire, and the taking of Constantinople, which happened in 1453, scattered the learned men of that country, many of whom took shelter in Italy, and brought with them their language, and the precious remains of ancient learning. The art of printing soon spread abroad these treasures, and in the sixteenth century geometry was very generally cultivated. Amongst the writers on the science in this century we may, in particular, reckon Zamberti, John Baptiste Memmius, Commandine, Guido Ubaldo, Maurolycus, and Tartalea. These and others laboured usefully on the ancients, by translations and commentaries. The Jesuit Clavius deserves particular mention. Besides his labour on Euclid, we owe to him a good work for the time on practical geometry in eight books.

We pass a multitude of names, and come to the French geometer Vieta, who was deeply versed in the ancient as well as in the modern geometry, and the restorer of the tangencies, one of the lost works of Apollonius. Adrian Metius, a Dutch geometer, deserves to be mentioned for his convenient and accurate approximate ratio (113 to 355) of the diameter to the circumference of a circle, given in a work on practical geometry. At this period the geometer Nonius, a professor at Coimbra, laboured with zeal in spreading a knowledge of the science in Portugal.

The seventeenth century opened propitiously for the progress of geometry. Lucas Valerius, an Italian, took up a subject which Archimedes had neglected, namely, the centre of gravity of solids; and Marinus Ghetaldus, another Italian, made an attempt to restore the lost book of Apollonius, entitled *De Inclinationibus;* but he left the labour incomplete. He also composed a work *De Resolutione et Compositione Mathematica*, which proves him to have imbibed the true spirit of the ancient geometry. A Scottish geometer, Alexander Anderson, lived at this time. He had a decided taste for the ancient analysis, of which he gave an essay in his *Supplementum Apollonii Redivivi*, in which he supplied what Ghetaldus had left imperfect. The Netherlands could boast of some geometers who did credit to their time. Ludolph Van Ceulen has been celebrated for his approximation to the ratio of the diameter of a circle to its circumference (ALGEBRA, art. 272), a prodigious effort of labour, but requiring little genius. Willebrord Snellius was a more distinguished geometer. He undertook the restoration of the lost book *De Sectione Determinata* of Apollonius, and accomplished his task creditably. He improved greatly the way in which Ceulen had approximated to the ratio of the diameter to the circumference, and verified the labour of that model of patience in calculation. Albert Girard has acquired great reputation in geometry by his supposed divination of the Porisms of Euclid; for in his edition of Stevinus he positively avers that he had restored the three books, which, however, never appeared; and indeed it may be doubted whether he understood the true nature of porisms. John Neper might be reckoned amongst geometers, but he has still higher claims to the notice of posterity for his invention of logarithms.

The science was sedulously cultivated in England at this period by Robert Record, John Dee, Leonard and Thomas Digges, and Henry Billingsley. Record was the author of the *Pathway of Knowledge*, the earliest book in the English language on geometry. It was first printed in

1551, and is dedicated to Edward VI. Edward Wright, the inventor of what is called *Mercator's Chart,* was an English geometer whose knowledge of the science greatly exceeded what was common in his time.

Germany had many geometers at this period, but none of a high order. John Werner of Nuremberg cultivated the ancient geometry, and excelled in a knowledge of its analysis. Every writer on geometry at this period gave a system of trigonometry nearly the same as we now have it in its most elementary form. To George Joachim Rheticus mathematical science is particularly indebted for a trigonometrical table, more extensive than any that had been given before him. It was printed in 1594, with this title, *Opus Palatinum de Triangulis;* but the author was then dead. The work was published by Valentine Otho.

Pitiscus, another German geometer, extended and reprinted this work in 1613, with the title of *Thesaurus Mathematicus, sive canon sinuum ad radium* 1,000,000,000, &c. This is indeed a treasure, and one of the most remarkable monuments of human patience extant.

Want of space compels us to pass in silence many names not less celebrated than some we have given, but less remarkable, because of their abundance in respect of the age to which they gave splendour. Indeed we may reckon that every astronomer and algebraist was then a geometer.

Kepler opened an unexplored way into the field of geometry, by boldly introducing the notion of infinity into that science. We may suppose that Archimedes must have entertained in effect the same idea in his speculations on the sphere and cylinder, but was prevented from following it to its full extent by the strict laws according to which the early mathematicians had constructed their demonstrations. The views of Kepler were eagerly seized by Roberval in France, and by Cavalieri in Italy. They were the fertile germs which, under the culture of such men, led, in the course of the seventeenth century, to a rich harvest of discoveries.

We have now arrived at a period at which the discoveries of the ancients formed but a small part of the whole body of geometrical science, augmented as it had been by the moderns, and which was continually increasing. The new views which were opened soon produced the methods of indivisibles of Cavalieri and Roberval, the theory of tangents of Fermat, the arithmetic of infinites of Wallis, the geometry of curve lines of Descartes, and, finally, the method of fluxions of Newton, and the differential calculus of Leibnitz. The origin and progress of these have been fully explained in our introductions to ALGEBRA and FLUXIONS, and require not to be here repeated. The ancient geometry, however, still had great value. Huygens and Newton delivered their sublime discoveries in its language, and represented the relations of time, space, velocity, force, the objects of their physical inquiries, by geometrical diagrams. The rigorous mode of ancient demonstrations served likewise as a model on which to form the processes of reasoning by which the new truths in geometry and physics were to be established.

Not to pass altogether in silence the names of geometers whose discoveries have made the seventeenth century ever memorable, we observe, that to Guildin, a Jesuit, we owe the discovery of a property of the centre of gravity applicable to the measurement of solids formed by revolution; and to Descartes, Fermat, Roberval, and Barrow, a method of determining the tangents of curves. Galileo first suggested the *cycloid,* the nature of which was afterwards fully disclosed by the investigations of Roberval, Fermat, Pascal, Huygens, Wren, and Wallis. James Gregory first suggested the logarithmic curve; and John Bernoulli and Leibnitz showed the true nature of the catenary, which Galileo could not discover; afterwards, David Gregory demonstrated its properties by the new geometry.

The ancient geometry came in for a share of that general attention which was bestowed on the modern theories. Newton, as has been already stated, held it in high esteem; and David Gregory and Dr Halley employed their genius and learning in restoring to their pristine excellence the precious remains of Euclid and Apollonius.

Previously to the time of Newton, pure geometry and algebra were the only subjects which mathematicians had for the exercise of their genius; but his sublime discoveries presented a new and an immense field for investigation. The fact that the orbits of the planets are ellipses, naturally connected the doctrines of astronomy with the conic sections; and the two were wrought up into the beautiful physico-mathematical theory of central forces delivered in the *Principia.* When this came to be fully understood, it served as a model of reasoning in all speculations on physics, and the geometrical method of Newton was adopted and imitated by his followers. Thus, we have the *Elements of Physical and Geometrical Astronomy* of David Gregory, and the *Phoronomia* of Herman, and many other like treatises, composed in the geometrical style. It was, however, soon discovered, and first by foreign mathematicians, that the geometrical method, which, when carried a certain length, is perspicuous and easy, is yet unsuitable to the more difficult speculations of mechanical philosophy, by reason of its cumbersomeness. It was therefore abandoned by Leibnitz, the Bernoullis, Euler, and their followers, and the greatly more manageable modern methods of the fluxional or differential calculus adopted in its stead. The mathematicians in Britain, who had imbibed deeply and acquired a relish for the spirit of the geometrical method, however, still adhered wholly or in part to that method. Maclaurin, the expositor of Newton's calculus of fluxions, defended its principles, and delivered many of his own fine speculations in the pure and mixed mathematics, in the prolix style of the ancient geometry. But he also gave a theory of the fluxional calculus in the more concise language of the modern analysis, which served as a practical example of the advantage which the latter has over the former as an instrument of invention. Dr Robert Simson, the editor of Euclid, greatly preferred the geometrical to the modern analysis; and his disciple, Dr Mathew Stewart, the author of *General Theorems, Tracts relating to Physical Astronomy,* and *Propositiones Geometricæ more Veterum Demonstratæ,* fully agreed with him in this sentiment. At a later period another Scottish professor, the late Mr Playfair, with a profound knowledge of both the ancient and modern analysis, and with no prejudice in favour of the former, yet gave an elegant example of its beauty, in his paper on the origin and investigation of porisms.

These distinguished Scottish mathematicians, by their writings, contributed greatly to keep up the taste for geometry in Britain during the last century. It is proper to acknowledge also, that much is due to Dr A. Robertson, the late professor of astronomy at Oxford, to Dr Horsley, bishop of Rochester, and others, for the estimation in which the geometrical analysis is now held in Britain.

The nature and objects of the ancient geometry have been fully understood for a century past, and the only question now is, how it ought to be studied. There have been a great variety of treatises within that time sent into the world. We do not, however, suppose that the science has gained by this diversity of guides. The settled public opinion seems to be in favour of some standard book; and Euclid's *Elements* have been, by almost universal consent, chosen as that standard in this country. There is another work of great excellence in the French language, *Eléments de Géométrie,* by the late Legendre, a mathematician of the highest celebrity. Were we to chuse a book different from Euclid for purposes of instruction, would be Legendre's Geometry, of which there is an Iglish translation. It may be useful to read more than oe book on a subject which we wish to understand thorughly, and those who hold this opinion can find no better bk than that of the French geometer. We have kept hn constantly in view in composing this treatise.

n tracing the progress of a science, it is always interting to know by what steps it has advanced in the creer of improvement. These may be well ascertained b consulting the authors who have written on the science, fm its infancy downwards. With this view we have gen a catalogue of writers on algebra and fluxions, and w now do the same in regard to geometry. The early wters are not so much mentioned for their excellence, as fm a wish to give a faithful portraiture of the state and pgress of the science at different periods. The works o geometry in the last century are too numerous to be al specified. Many have fallen into obscurity. Almost al are mere transcripts from Euclid; indeed, generally spaking, their excellence is in proportion to the fidelity wh which they have copied the ancient.

General Notions of Geometrical Magnitude.

Our notions of geometrical magnitudes are obtained by the contemplation of a *body*, or *solid*. We readily understand that this is extended in three directions; that is, it has length, breadth, and thickness. The outside or boundary of a solid, that which separates the particular space it occupies from space in general, is called a *surface* or *superficies*. A surface, then, is not conceived as having any thickness; it has only length and breadth.

A surface has a boundary; something which encloses it, or separates any portion of it from the remainder. This boundary, which has no thickness, nor breadth, but length only, is a *line*.

Again, there is something which terminates a line, indicating where it begins and where it ends, or which may

Lines and Figures upon a Plane.

separate it into distinct portions. This is a point, which has neither thickness, length, nor breadth. These three kinds of magnitude, viz. solids, surfaces, and lines, are the objects of geometrical discussion.

There is no limit to the number of lines, and surfaces, and solids, which may be considered in geometry. The elements of the science, however, treat only of a few of these: Straight lines, circles, rectilineal plane figures, and their affections, constitute one part of geometry; another treats of the intersections of planes, of solids bounded by planes, and of the three round bodies, viz. the cylinder, the cone, and the sphere. This diversity of objects leads to the division of the subject into two parts, one which treats of figures on a plane, and another the geometry of solids.

PART I.—OF LINES AND FIGURES UPON A PLANE.

SECT. I.—PRINCIPLES OF GEOMETRY.

Definitions.

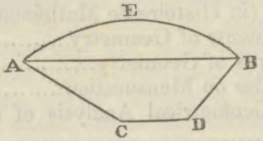
I. Geometry is a science which treats of the properties and relations of quantities having extension, and which are called magnitudes. Extension is distinguished into length, breadth, and thickness.

II. A *Point* is that which has position, but not magnitude.

III. A *Line* is that which has only length. Hence the extremities of a line are points, and the intersections of one line with another are also points.

IV. A *Straight* or *Right Line* is the shortest way from on point to another.

Fig. 1.



V. Every line which is neither straight nor composed of straight lines is a *Curve Line*. Thus AB is a straight line, ACDB is a line made up of straight lines, and AEB is a curve line.

VI. A *Superficies* or *Surface* is that which has only length and breadth. Hence the extremities of a superficies are lines, and the intersections of one superficies with another are also lines.

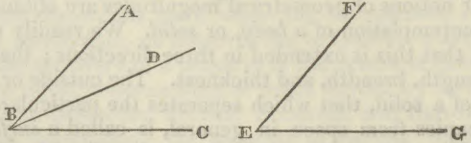
VII. A *Plane Superficies* is that in which any two points being taken, the straight line between them lies wholly in that superficies.

VIII. Every superficies which is neither plane nor composed of plane superficies, is a *Curve Superficies*.

IX. A *Solid* is that which has length, breadth, and thickness. Hence the boundaries of a solid are superficies; and the boundary which is common to two solids which are contiguous, is a superficies.

X. A *Plane Rectilineal Angle* is the inclination of two straight lines to one another, which meet together, but are not in the same straight line. The point in which the lines meet one another is called the *Vertex* of the angle.

Fig. 2.



When there is only one angle at a point, it may be expressed by the letter placed at that point; thus the angle contained by the lines EF and EG may be called the angle E. If, however, there be several angles, as at B, then each is expressed by three letters, one of which is the letter that stands at the vertex of the angle, and the others are the letters that stand somewhere upon the lines containing the angle, the letter at the vertex being placed between the other two. Thus the angle contained by the lines BA and BD is called the angle ABD or DBA.

Angles, in common with other quantities, admit of addition, subtraction, multiplication, and division. Thus the sum of the angles ABD and ABC is the angle DBC; the difference of the angles DBC and ABD is the angle ABC.

Fig. 3.

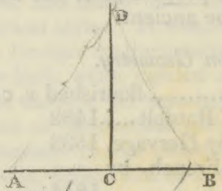


Fig. 4.

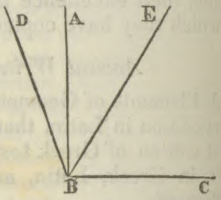
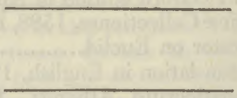


XI. When a straight line standing on another straight line makes the adjacent angles equal to one another, each of them is called a *Right Angle*, and the straight line which stands on the other is called a *Perpendicular* to it. Thus, if DC meet AB, and make the angles ACD, DCB equal to one another, each of them is a right angle, and DC is a perpendicular to AB.

XII. An *Obtuse Angle* is that which is greater than a right angle, and an *Acute Angle* is that which is less than a right angle. Thus ABC being supposed a right angle, DBC is an obtuse angle, and EBC an acute angle.

XIII. *Parallel Straight Lines* are such as are in the same plane, and which being produced ever so far both ways, do not meet.

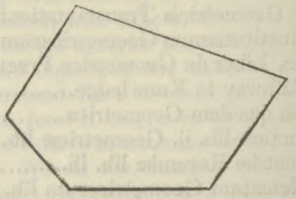
Fig. 5.



XIV. A *Plane Figure* is a plane terminated everywhere by lines.

If the lines be straight, the space which they enclose is called a *Rectilineal* figure, or a *Polygon*, and the lines themselves constitute the *Perimeter* of the polygon.

Fig. 6.



XV. When a polygon has three sides (which is the smallest number it can have), it is called a *Triangle*; when it has four, it is called a *Quadrilateral*; when it has five, a *Pentagon*; when six, a *Hexagon*, &c.

XVI. An *Equilateral* triangle is that which has three equal sides (fig. 7); an *Isosceles* triangle is that which has only two equal sides (fig. 8); and a *Scalene* triangle is that which has all its sides unequal (fig. 10).

Fig. 7.

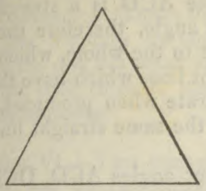


Fig. 8.

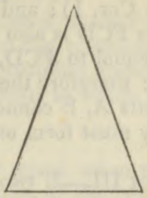
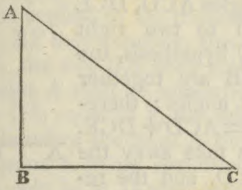


XVII. A *Right-angled* triangle is that which has a right a gle; the side opposite to the right angle is called the *ypothenuse.* Thus in the triangle ABC, having the a gle at B a right angle, the side AC is the hypothenuse.

Fig. 9.



XVIII. An *Obtuse-angled* triangle is that which has an o use angle (fig. 10); and an *acute-angled* triangle is that ich has three acute angles (fig. 11).

Fig. 10.

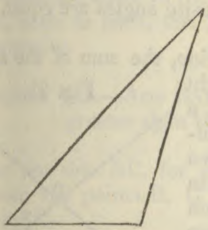


Fig. 11.

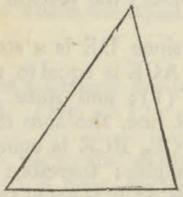

IX. Of quadrilateral figures, a *square* is that which h all its sides equal, and all its angles right angles (fig. 1 . A *Rectangle* is that which has all its angles right a les, but not all its sides equal (fig. 13). A *Rhombus* i hat which has all its sides equal, but its angles are not r t angles (fig. 14). A *Parallelogram*, or *Rhomboid*, is t t which has its opposite sides parallel (fig. 15). A *apezoid* is that which has only two of its opposite sides p allel (fig. 16).

Fig. 12.

Fig. 13.

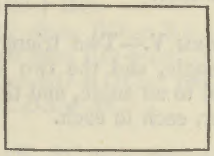

Fig. 15.

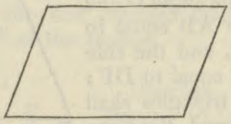

Fig. 14.

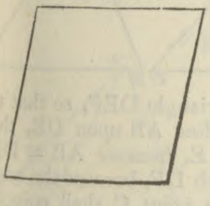

Fig. 16.

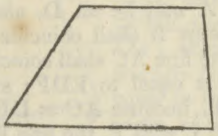


Lines and Figures upon a Plane.

XX. A *Diagonal* is a straight line which joins the vertices of two angles, which are not adjacent to each other, such as AC in fig. 42.

XXI. An *Equilateral Polygon* is that which has all its sides equal; and an *Equiangular Polygon* is that which has all its angles equal. If a polygon be both equilateral and equiangular, it is called a *Regular Polygon.*

XXII. Two polygons are *equilateral* between themselves when the sides of the one are equal to the sides of the other, each to each, and in the same order; that is, when in going about each of the figures in the same direction, the first side of the one is equal to the first side of the other; the second side of the one is equal to the second side of the other; the third to the third, and so on. The same is to be understood of two polygons which are *equiangular* between themselves.

Explanation of Terms.

An *Axiom* is a proposition the truth of which is evident at first sight.

A *Theorem* is a truth which becomes evident by a process of reasoning called *Demonstration.*

A *Problem* is a question proposed, which requires a solution.

A *Lemma* is a subsidiary truth employed in the demonstration of a theorem, or the solution of a problem.

The common name, *Proposition*, is given indifferently to theorems, problems, and lemmas.

A *Corollary* is a consequence which follows from one or several propositions.

A *Scholium* is a remark upon one or more propositions that have gone before, tending to show their connection, their restriction, their extension, or the manner of their application.

A *Hypothesis* is a supposition made either in the enunciation of a proposition, or in the course of a demonstration.

Explanation of Signs.

That the demonstrations may be more concise, we shall make use of the following signs borrowed from algebra; and in employing them we shall take for granted that the reader is acquainted with at least the notation and first principles of that branch of mathematics.

To express that two quantities are equal, the sign $=$ is put between them; thus $A = B$ signifies that the quantity denoted by A is equal to the quantity denoted by B.

To express that A is less than B they are written thus, $A < B$.

To express that A is greater than B they are written thus, $A > B$.

The sign $+$ (read *plus*) written between the letters which denote two quantities, indicates that the quantities are to be added together; thus $A + B$ means the sum of the quantities A and B.

The sign $-$ (read *minus*) written between two letters means the excess of the one quantity above the other; thus $A - B$ means the excess of the quantity denoted by A above the quantity denoted by B. The signs $+$ and $-$ will sometimes occur in the same expression; thus $A + C - D$ means that D is to be subtracted from the sum of A and C; also $A - D + C$ means the same thing.

The sign $\times$ put between two quantities means their product if they be considered as numbers; but if they be considered as lines, it signifies a rectangle having these lines for its length and breadth; thus $A \times B$ means the product of two numbers A and B; or else a rectangle having A and B for the sides about one of its right angles. We shall likewise indicate the product of two quantities, in some cases, by writing the letters close together; thus mA will be used to express the product of m and A, and so on with other expressions, agreeably to the common notation in algebra.

The expression A^2 means the square of the quantity A, and A^3 means the cube of A; also PQ^2 and PQ^3 mean, the one the square, and the other the cube, of a line whose extremities are the points P and Q.

On the other hand, the sign $\surd$ indicates a root to be extracted; thus $\sqrt{A \times B}$ means the square root of the product of A and B.

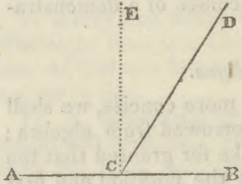
Axioms.

1. Two quantities, each of which is equal to a third, are equal to one another.
2. The whole is greater than its part.
3. The whole is equal to the sum of all its parts.
4. Only one straight line can be drawn between two points.
5. Two magnitudes, whether they be lines, surfaces, or solids, are equal, when, being applied the one to the other, they coincide with one another entirely, that is, when they exactly fill the same space.
6. All right angles are equal to one another.

Note.—The references are to be understood thus: (7) refers to the seventh proposition of the section in which it occurs; (4, 2) means the fourth proposition of the second section; (2 Cor. 28, 4) means the second corollary to the twenty-eighth proposition of the fourth section.

Theorem I.—A straight line CD, which meets with another AB, makes with it two adjacent angles, which, taken together, are equal to two right angles.

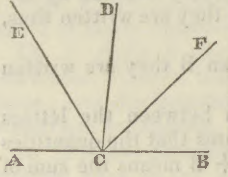
Fig. 17.



At the point C let CE be perpendicular to AB. The angle ACD is the sum of the angles ACE, ECD; therefore ACD + BCD is the sum of the three angles ACE, ECD, BCD. The first of these is a right angle, and the two others are together equal to a right angle; therefore the sum of the two angles ACD, BCD, is equal to two right angles.

Cor. 1. If one of the angles is a right angle, the other is also a right angle.

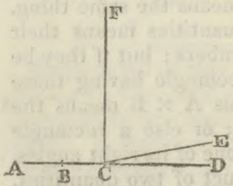
Fig. 18.



Cor. 2. All the angles ACE, ECD, DCF, FCB, at the same point C, on the same side of the line AB, are, taken together, equal to two right angles. For their sum is equal to the two angles ACD, DCB.

Theorem II.—Two straight lines which coincide with each other in two points, also coincide in all their extent, and form but one and the same straight line.

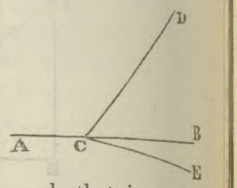
Fig. 19.



Let the points which are common to the two lines be A and B; in the first place it is evident that they must coincide entirely between A and B; otherwise two straight lines could be drawn from A to B, which is impossible (Axiom 4). Now let us suppose, if possible, that the lines when produced separate from each other at a point C, the one becoming ACD, and the other ACE. At the point C let CF be drawn, so as to make the angle ACF a right angle; then ACE being a straight line, the angle FCE is a right angle (1 Cor. 1); and because ACD is a straight line, the angle FCD is also a right angle, therefore the angle FCE is equal to FCD, a part to the whole, which is impossible; therefore the straight lines which have the common points A, B cannot separate when produced, therefore they must form one and the same straight line.

Theorem III.—If two adjacent angles ACD, DCB make together two right angles; the two exterior lines AC, CB, which form these angles, are in the same straight line.

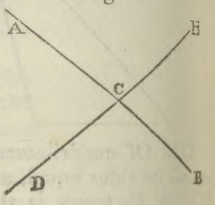
Fig. 20.



For if CB is not the line AC produced, let CE be that line produced, then, ACE being a straight line, the angles ACD, DCE are together equal to two right angles (1); but, by hypothesis, the angles ACD, DCB are together equal to two right angles; therefore $ACD + DCB = ACD + DCE$. From these equals take away the common angle ACD, and the remaining angles DCB, DCE are equal, that is, a part equal to the whole, which is impossible; therefore CB is the line AC produced.

Theorem IV.—If two straight lines AB, DE cut each other; the vertical or opposite angles are equal.

Fig. 21.



For since DE is a straight line, the sum of the angles ACD, ACE is equal to two right angles (1); and since AB is a straight line, the sum of the angles ACE, BCE is equal to two right angles; therefore the sum ACD + ACE is equal to the sum ACE + BCE. From each of these take away the same angle ACE, and there remains the angle ACD equal to its opposite angle BCE.

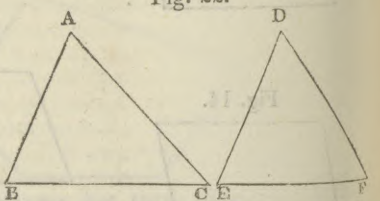
In like manner it may be demonstrated, that the angle ACE is equal to its opposite angle BCD.

Cor. 1. From this it appears, that if two straight lines cut one another, the angles they make at the point of their intersection are together equal to four right angles.

Cor. 2. And hence all the angles made by any number of lines meeting in one point are together equal to four right angles.

Theorem V.—Two triangles are equal when they have an angle, and the two sides containing it of the one, equal to an angle, and the two sides containing it of the other, each to each.

Fig. 22.



Let the triangles ABC, DEF have the angle A equal to the angle D, the side AB equal to DE, and the side AC equal to DF; the triangles shall be equal. For if the triangle ABC be applied to the triangle DEF, so that the point A may be on D, and the line AB upon DE, then the point B shall coincide with E, because $AB = DE$; and the line AC shall coincide with DF, because the angle BAC is equal to EDF; and the point C shall coincide with F, because $AC = DF$; and since B coincides with E, and C with F, the line BC shall coincide with EF, and

Lines and Figures upon a Plane.

the two triangles shall coincide exactly, the one with the other; therefore they are equal (Ax. 5).

Cor. Hence it follows that the bases, or third sides BC, EF of the triangles are equal; and the remaining angles B, C of the one are equal to the remaining angles E, F of the other, each to each, namely, those to which the equal sides are opposite.

Theorem VI.—Two triangles are equal, when they have a side, and the two adjacent angles of the one equal to a side, and the two adjacent angles of the other, each to each. (See fig. 22.)

Let the side BC be equal to the side EF, the angle B to the angle E, and the angle C to the angle F; the triangle ABC shall be equal to the triangle DEF. For if the triangle ABC be applied to the triangle DEF, so that the equal sides BC, EF may coincide, then, because the angle B is equal to E, the side BA shall coincide with ED, and therefore the point A shall be somewhere in ED; and because the angle C is equal to F, the side CA shall coincide with FD, and therefore the point A shall be somewhere in FD; now the point A being somewhere in the lines ED and FD, it can only be at D their intersection; therefore the two triangles ABC, DEF must entirely coincide, and be equal to one another.

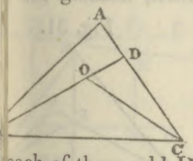
Cor. Hence it appears that the remaining angles A, D of the triangles are equal; and the remaining sides AB, AC of the one are equal to the remaining sides DE, DF of the other, each to each, viz. those to which the equal angles are opposite.

Theorem VII.—Any two sides of a triangle are together greater than the third. (Fig. 22.)

For the side BC, for example, being the shortest way between the points B, C (Def. 4), it must be less than BA + AC.

Theorem VIII.—If from a point O, within a triangle ABC, there be drawn straight lines OB, OC to the extremities of BC, one of its sides; the sum of these lines shall be less than that of AB, AC, the two other sides.

Fig. 23.

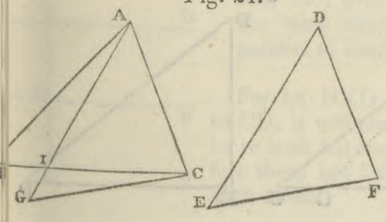


Let BO be produced to meet CA in D; because the straight line OC is less than OD + DC, to each of these add BO, and $BO + OC \angle BO + OD + DC$; that is, $BO + OC \angle BD + DC$.

Again, since $BD \angle BA + AD$, to each of these add DC, and we have $BD + DC \angle BA + AC$; but it has been shown that $BO + OC \angle BD + DC$, much more then is $BO + OC \angle BA + AC$.

Theorem IX.—If two sides AB, AC of a triangle ABC be equal to two sides DE, DF of another triangle DEF, each to each, but the angle BAC contained by the former greater than the angle EDF contained by the latter; the third side BC of the first triangle shall be greater than the third side EF of the second.

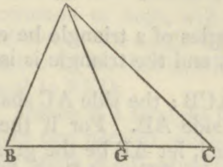
Fig. 24.



Suppose AG drawn so that the angle CAG = D, take AG = DE and join CG; then the triangle GAC is equal to the triangle EDF (5), and therefore GC = EF. Now there may be three cases, according as the point G falls without the triangle BAC, fig. 24, or on the side BC, fig. 25, or within the same triangle, fig. 26.

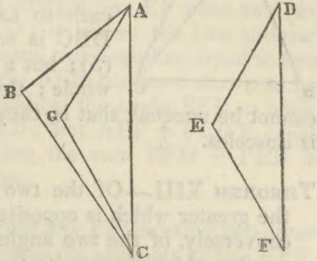
Case I. Because $GC \angle GI + IC$, and $AB \angle AI + IB$ (7), therefore $GC + AB \angle GI + AI + IC + IB$, that is, $GC + AB \angle AG + BC$; from each of these unequal quantities take away the equal quantities AB, AG, and there remains $GC \angle BC$, therefore $EF \angle BC$.

Fig. 25.



Case II. If the point G fall upon the side BC, then it is evident that GC, or its equal EF, is less than BC.

Fig. 26.



Case III. Lastly, if the point G fall within the triangle BAC, then $AG + GC \angle AB + BC$ (8), therefore, taking away the equal quantities AG, AB, there remains $GC \angle BC$ or $EF \angle BC$.

Cor. Hence, conversely, if EF be less than BC, the angle EDF is less than BAC; for the angle EDF cannot be equal to BAC, because then (5), EF would be equal to BC; neither can the angle EDF be greater than BAC, for then (by the Theor.) EF would be greater than BC.

Theorem X.—Two triangles are equal, when the three sides of the one are equal to the three sides of the other, each to each. (Fig. 22.)

Let the side AB = DE, AC = DF, and BC = EF; then shall the angle A = D, B = E, C = F.

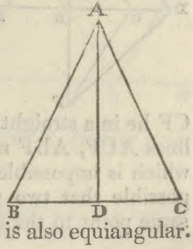
For if the angle A were greater than D; since the sides AB, AC are equal to DE, DF, each to each, it would follow (9), that BC would be greater than EF; and if the angle A were less than the angle D, then BC would be less than EF; but BC is equal to EF, therefore the angle A can neither be greater nor less than the angle D, therefore it must be equal to it. In the same manner it may be proved that the angle B = E, and that the angle C = F.

Scholium. It may be remarked, as in Theorem V. and Theorem VI. that the equal angles are opposite to the equal sides.

Theorem XI.—In an isosceles triangle, the angles opposite to the equal sides are equal to one another.

Let the side AB = AC, then shall the angle C = B.

Fig. 27.



Suppose a straight line drawn from A the *vertex* of the triangle, to D the middle of its base; the two triangles ABD, ACD have the three sides of the one equal to the three sides of the other, each to each, namely, AD common to both, AB = AC by hypothesis, and BD = DC by construction, therefore (preced. Theor.) the angle B is equal to the angle C.

Cor. Hence, every equilateral triangle is also equiangular.

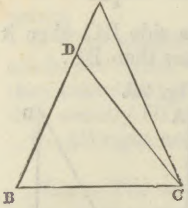
Lines and Figures upon a Plane.

Scholium. From the equality of the triangles ABD, ACD, it follows that the angle BAD = DAC, and that the angle BDA = ADC; therefore these two last are right angles. Hence it appears that a straight line drawn from the vertex of an isosceles triangle to the middle of its base is perpendicular to that base, and divides the vertical angle into two equal parts.

In a triangle that is not isosceles, any one of its three sides may be taken indifferently for a *base;* and then its *vertex* is that of the opposite angle. In an isosceles triangle, the base is that side which is not equal to one of the others.

Theorem XII.—If two angles of a triangle be equal; the opposite sides are equal, and the triangle is isosceles.

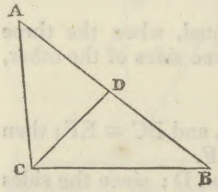
Fig. 28.



Let the angle ABC = ACB; the side AC shall be equal to the side AB. For if the sides are not equal, let AB be the greater of the two; take BD = AC, and join CD; the angle DBC is by hypothesis equal to ACB, and the two sides DB, BC are equal to the two sides AC, BC, each to each; therefore the triangle DBC is equal to the triangle ACB (5); but a part cannot be equal to the whole; therefore the sides AB, AC cannot be unequal, that is, they are equal, and the triangle is isosceles.

Theorem XIII.—Of the two sides of a triangle, that is the greater which is opposite to the greater angle; and conversely, of the two angles of a triangle, that is the greater which is opposite to the greater side.

Fig. 29.

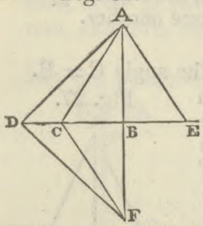


First, let the angle C > B; then shall the side AB opposite to C be greater than the side AC opposite to B. Suppose CD drawn, so that the angle BCD = B; in the triangle BDC, BD is equal to DC (12); but AD + DC > AC, and AD + DC = AD + DB = AB, therefore AB > AC.

Next, let the side AB > AC; then shall the angle C opposite to AB, be greater than the angle B, opposite to AC. For if C were less than B, then, by what has been demonstrated, AB < AC, which is contrary to the hypothesis of the proposition, therefore C is not less than B; and if C were equal to B, then it would follow that AC = AB (12), which is also contrary to the hypothesis; therefore C is greater than B.

Theorem XIV.—From a point A without a straight line DE, no more than one perpendicular can be drawn to that line.

Fig. 30.



For suppose it possible to draw two, AB and AC; produce one of them AB, so that BF = AB, and join CF. The triangle CBF is equal to the triangle ABC, for the angle CBF is a right angle, as well as CBA, and the side BF = BA; therefore the triangles are equal (5), and hence the angle BCF = BCA; but the angle BCA is by hypothesis a right angle; therefore the angle BCF is also a right angle; hence AC and CF lie in a straight line (3), and consequently two straight lines ACF, ABF may be drawn between two points A, F, which is impossible (Axiom 4); therefore it is equally impossible that two perpendiculars can be drawn from the same point to the same straight line.

Theorem XV.—If from a point A, without a straight line DE, a perpendicular AB be drawn upon that line, and also different oblique lines AE, AC, AD, &c. to different points of the same line.

First, The perpendicular AB shall be shorter than any one of the oblique lines.

Secondly, The two oblique lines AC, AE, which meet the line DE on opposite sides of the perpendicular, and at equal distances BC, BE from it, are equal to one another.

Lastly, Of any two oblique lines AC, AD, or AE, AD, that which is more remote from the perpendicular is the greater.

Produce the perpendicular AB, so that BF = BA, and join FC, FD.

1. The triangle BCF is equal to the triangle BCA; for the right angle CBF = CBA, the side CB is common, and the side BF = BA, therefore the third side CF = AC (5); but AF < AC + CF (7), that is, 2AB < 2AC; therefore AB < AC; that is, the perpendicular is shorter than any one of the oblique lines.

2. If BE = BC, then, as AB is common to the two triangles ABE, ABC, and the right angle ABE = ABC, the triangles ABE, ABC shall be equal (5), and AE = AC.

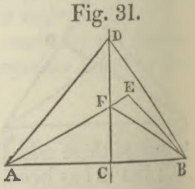
3. In the triangle DFA, the sum of the lines AD, DF is greater than the sum of AC, CF (8), that is, 2AD > 2AC; therefore AD > AC, that is, the oblique line, which is more remote from the perpendicular, is greater than that which is nearer.

Cor. 1. The perpendicular measures the distance of any point from a straight line.

Cor. 2. From the same point three equal straight lines cannot be drawn to terminate in the same straight line; for if they could be drawn, then two of them would be on the same side of the perpendicular, and equal to each other, which is impossible.

Theorem XVI.—If from C, the middle of a straight line AB, a perpendicular CD be drawn to that line; first, every point in the perpendicular is equally distant from the extremities of the line AB; secondly, every point without the perpendicular is at unequal distances from the same extremities A, B.

Fig. 31.

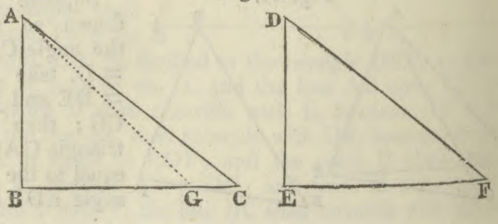


1. Let D be any point in CD; then, because the two oblique lines DA, DB are equally distant from the perpendicular, they are equal to one another (15); therefore every point in CD is equally distant from the extremities of AB.

2. Let E be a point out of the perpendicular; join EA, EB; one of these lines must cut the perpendicular in F; join BF, then AF = BF, and AE = BF + FE; but BF + FE > BE (7), therefore AE > BE, that is, E any point out of the perpendicular is at unequal distances from the extremities of AB.

Theorem XVII.—Two right-angled triangles are equal, when the hypothenuse and a side of the one are equal to the hypothenuse and a side of the other, each to each.

Fig. 32.

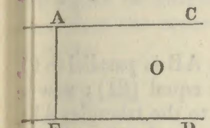


Lines and Figures upon a Plane.

Let the hypothenuse AC = DF, and the side AB = DE; the triangle ABC shall be equal to DEF. The proposition will evidently be true (10), if the remaining sides BC, EF are equal. Now, if it be possible to suppose that they are unequal, let BC be the greater, take BG = EF, and join AG; then the triangles ABG, DEF, having the side AB = DE, BG = EF, and the angle B = E, will be equal to one another (5), and will have the remaining side AG = DF; but by hypothesis DF = AC; therefore AG = AC; but AG cannot be equal to AC (15), therefore it is impossible that BC can be unequal to EF, and therefore the triangles ABC, DEF, are equal to one another.

Theorem XVIII.—Two straight lines AC, ED, which are perpendicular to a third straight line AE, are parallel to each other.

Fig. 33.

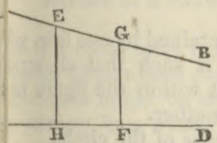


For if they could meet at a point O, then two perpendiculars OA, OE, might be drawn from the same point O, to the straight line AE, which is impossible (14).

In the next theorem, it is necessary to assume another axiom, in addition to those already laid down in the beginning of this section.

Axiom 7.

Fig. 34.

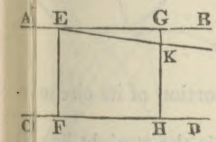


If two points E, G in a straight line AB are situated at unequal distances EH, GF from another straight line CD in the same plane; these two lines, when indefinitely produced, on the side of the least distance GH, will meet each other.

Theorem XIX.—If two straight lines AB, CD be parallel; perpendiculars EF, GH to one of the lines, which are terminated by the other line, are equal, and are perpendicular to both the parallels.

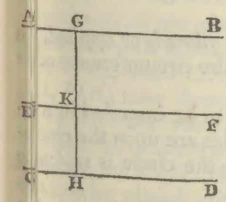
For if EF and GH, which are perpendicular to CD, were unequal, the lines AB, CD would meet each other (by the above axiom), which is contrary to the supposition that they are parallel. And if EF, GH be not perpendicular to AB, let EK be perpendicular to EF, meeting GH in K; then, because EK and FH are perpendicular to EF, they are parallel (18); and therefore, by what has been just shown, the perpendiculars EF, KH must be equal; but by hypothesis EF = GH, therefore KH = GH, which is impossible; therefore EF is perpendicular to AB; and in the same way it may be shown that GH is perpendicular to AB.

Fig. 35.



Cor. Hence it appears, that through the same point E, no more than one parallel can be drawn to the same straight line CD.

Fig. 36.

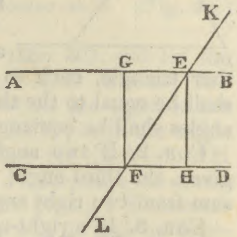


Theorem XX.—Straight lines AB, EF, which are parallel to the same straight line CD, are parallel to each other.

For let HKG be perpendicular to CD, it will also be perpendicular to both AB and EF (19); therefore these last lines are parallel to each other.

Theorem XXI.—If a straight line EF meet two parallel straight lines AB, CD; it makes the alternate angles AEF, EFD equal.

Fig. 37.



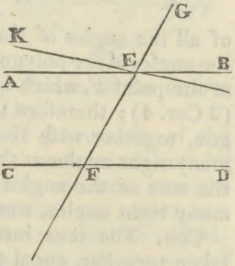
Let EH and GF be perpendicular to CD, then these lines will be parallel (18), and also at right angles to AB (19), and therefore FH and GE are equal to one another (19); therefore the triangles FGE, FHE, having the side FG = HE, and GE = FH, and FE common to both, will be equal; and hence the angle FEG will be equal to EFH, that is, FEA, will be equal to EFD.

Cor. 1. Hence if a straight line KL intersect two parallel straight lines AB, CD; it makes the exterior angle KEB equal to the interior and opposite angle EFD on the same side of the line. For the angle AEF = KEB, and it has been shown that AEF = EFD; therefore KEB = EFD.

Cor. 2. Hence also, if a straight line EF meet two parallel straight lines AB, CD; it makes the two interior angles BEF, EFD on the same side together, equal to two right angles. For the angle AEF has been shown to be equal to EFD; therefore, adding the angle FEB to both, AEF + FEB = EFD + FEB; but AEF + FEB is equal to two right angles, therefore the sum EFD + FEB is also equal to two right angles.

Theorem XXII.—If a straight line EF, meeting two other straight lines AB, CD, makes the alternate angles AEF, EFD equal; those lines shall be parallel.

Fig. 38.

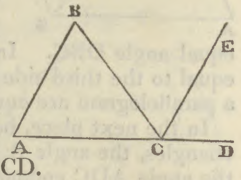


For if AE is not parallel to CD, suppose, if possible, that some other line KE can be drawn through E, parallel to CD; then the angle KEF must be equal to EFD (21), that is (by hypothesis), to AEF, which is impossible; therefore, neither KE, nor any other line drawn through E, except AB, can be parallel to CD.

Cor. If a straight line EF intersecting two other straight lines AB, CD, makes the exterior angle GEB equal to the interior and opposite angle EFD on the same side; or the two interior angles BEF, EFD on the same side equal to two right angles; in either case the lines are parallel. For if the angle GEB = EFD, then also AEF = EFD (4). And if BEF + EFD = two right angles, then, because BEF + AEF = two right angles (1), BEF + EFD = BEF + AEF, and taking BEF from both, EFD = AEF, therefore (by the theorem) in each case the lines are parallel.

Theorem XXIII.—If a side AC of a triangle ABC be produced towards D; the exterior angle BCD is equal to both the interior and opposite angles BAC, ABC.

Fig. 39.



Let CE be parallel to AB, then the angle B = BCE (21), and the angle A = ECD (1 Cor. 21), therefore B + A = BCE + ECD = BCD.

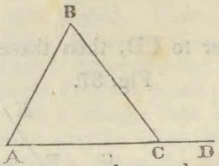
Cor. The exterior angle of a triangle is greater than either of the interior opposite angles.

Theorem XXIV.—The three interior angles of a triangle ABC taken together are equal to two right angles.

Lines and Figures upon a Plane.

For if AC be produced to D, then $A + B = BCD$, (23); to each of these equal quantities add ACB, then shall $A + B + ACB = BCD + BCA$; but $BCD + BCA =$ two right angles (1), therefore $A + B + ACB =$ two right angles.

Fig. 40.



Cor. 1. If two angles of one triangle be equal to two angles of another triangle, each to each; the third angle of the one shall be equal to the third angle of the other, and the triangles shall be equiangular.

Cor. 2. If two angles of a triangle, or their sum, be given, the third angle may be found, by subtracting their sum from two right angles.

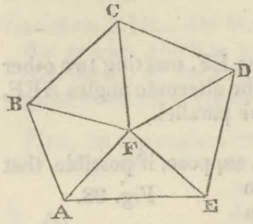
Cor. 3. In a right-angled triangle, the sum of the two acute angles is equal to a right angle.

Cor. 4. In an equilateral triangle, each of the angles is equal to the third part of two right angles, or to two thirds of one right angle.

Theorem XXV.—The sum of all the interior angles of a polygon is equal to twice as many right angles, wanting four, as the figure has sides.

Let ABCDE be a polygon; from a point F within it draw straight lines to all its angles, then the polygon shall be divided into as many triangles as it has sides; but the sum of the angles of each triangle is equal to two right angles (24); therefore, the sum of all the angles of the triangles is equal to twice as many right angles as there are triangles, that is, as the figure has sides; but the sum of all the angles of the triangles is equal to the sum of all the angles of the polygon, together with the sum of the angles at the point F, which last sum is equal to four right angles (2 Cor. 4); therefore the sum of all the angles of the polygon, together with four right angles, is equal to twice as many right angles as the figure has sides, and consequently the sum of the angles of the polygon is equal to twice as many right angles, wanting four, as the figure has sides.

Fig. 41.

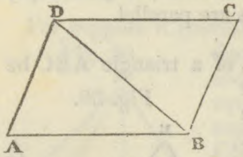


Cor. The four interior angles of a quadrilateral are, taken together, equal to four right angles.

Theorem XXVI.—The opposite sides of a parallelogram are equal, and the opposite angles are also equal.

Draw the diagonal BD; the two triangles ADB, DBC have the side BD common to both, and AB, DC being parallel, the angle $ABD = BDC$ (21), also, AD, BC being parallel, the angle $ADB = DBC$; therefore the two triangles are equal (6), and the side AB, opposite to the angle ADB, is equal to DC, opposite to the equal angle DBC. In like manner the third side AD is equal to the third side BC, therefore the opposite sides of a parallelogram are equal.

Fig. 42.



In the next place, because of the equality of the same triangles, the angle A is equal to the angle C, and also the angle ADC composed of the two angles ADB, BDC is equal to the angle ABC composed of the angles CBD, DBA; therefore the opposite angles of a parallelogram are also equal.

Theorem XXVII.—If the opposite sides of a quadrilateral ABCD be equal, so that $AB = DC$, and $AD = BC$; then, the equal sides are parallel, and the figure is a parallelogram. (Fig. 42.)

Draw the diagonal BD. The two triangles ABD, CDB have the three sides of the one equal to the three sides of the other, each to each, therefore the triangles are equal (10); and the angle ADB, opposite to AB, is equal to DBC opposite to DC; therefore the side AD is parallel to BC (22). For a similar reason AB is parallel to DC; therefore the quadrilateral ABCD is a parallelogram.

Theorem XXVIII.—If two opposite sides AB, DC of a quadrilateral be equal and parallel; the two other sides are in like manner equal and parallel; and the figure is a parallelogram. (Fig. 42.)

Draw the diagonal BD. Because AB is parallel to CD, the alternate angles ABD, BDC are equal (21); now the side $AB = DC$, and DB is common to the triangles ABD, BDC, therefore these triangles are equal (5), and hence the side $AD = BC$, and the angle $ADB = DBC$, consequently AD is parallel to BC (22), therefore the figure ABCD is a parallelogram.

SECT. II.—OF THE CIRCLE.

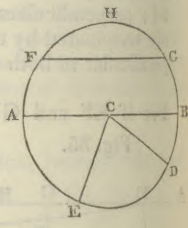
Definitions.

I. A *Circle* is a plane figure contained by one line, which is called the *circumference*, and is such that all straight lines drawn from a certain point within the figure to the circumference are equal to one another.

And this point is called the *centre* of the circle.

II. Every straight line CA, CE, CD, &c. drawn from the centre to the circumference, is called a *Radius* or *Semidiameter*; and every straight line, such as AB, which passes through the centre, and is terminated both ways by the circumference, is called a *Diameter*.

Fig. 43.



Hence it follows that all the radii of a circle are equal, and all the diameters are also equal, each being the double of the radius.

III. An *Arch* of a circle is any portion of its circumference, as FHG.

The *chord* or *subtense* of an arch is the straight line FG which joins its extremities.

IV. A *Segment* of a circle is the figure contained by an arch and its chord. If the figure be the half of the circle it is called a *Semicircle*.

Note. Every chord corresponds to two arches, and consequently to two segments; but in speaking of these, it is always the smallest that is meant, unless the contrary be expressed.

V. A *Sector* of a circle is the figure contained by an arch DE and the two radii CD, CE, drawn to the extremities of the arch. If the radii be at right angles to each other, it is called a *Quadrant*.

VI. A straight line is said to be *placed*, or *applied*, in a circle, when its extremities are in the circumference of the circle, as FG.

VII. A rectilineal figure is said to be *inscribed* in a circle, when the vertices of all its angles are upon the circumference of the circle; in this case, the circle is said to be *circumscribed* about the figure.

VIII. A straight line is said to *touch* a circle, or to be a

Lines and Figures upon a Plane.

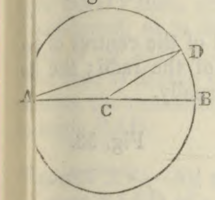
tangent to a circle, when it meets the circumference in one point only; such, for example, is BD, fig. 49. The point A which is common to the straight line and circle, is called the *Point of Contact*.

X. A polygon is said to be *described* or *circumscribed* about a circle, when all its sides are tangents to the circle; and in this case, the circle is said to be *inscribed* in the polygon.

Theorem I.—Any diameter AB divides the circle, and its circumference, into two equal parts. (Fig. 43.)

For if the figure AEB be applied to AFB, so that the base AB may be common to both, the curve line AEB must fall exactly upon the curve line AFB; otherwise there would be points in the one, or the other, unequally distant from the centre, which is contrary to the definition of a circle.

Fig. 44.



Theorem II.—Every chord is less than the diameter.

Let the radii CA, CD be drawn from the centre to the extremities of the chord AD; then the straight line AD is less than AC + CD, that is, $AD \angle AB$.

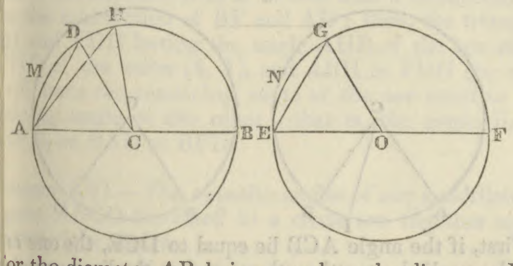
Theorem III.—A straight line cannot meet the circumference of a circle in more than two points.

For if it could meet it in three, these three points would be equally distant from the centre, and therefore three equal straight lines might be drawn from the same point to the same straight line, which is impossible (2 Cor. 15, 1).

Theorem IV.—In the same circle, or in equal circles, equal arches are subtended by equal chords; and, conversely, equal chords subtend equal arches.

If the radius AC be equal to the radius EO, and the arch AMD equal to the arch ENG; the chord AD shall be equal to the chord EG.

Fig. 45.



For the diameter AB being equal to the diameter EF, the semicircle AMDB may be applied exactly upon the semicircle ENGF, and then the curve line AMDB shall coincide entirely with the curve line ENGF; but the arch AMD being supposed equal to ENG, the point D must fall upon G, therefore the chord AD is equal to the chord EG.

Conversely, if the chord AD = EG, the arch AMD is equal to the arch ENG.

For if the radii CD, OG be drawn, the two triangles ACD, EOG have three sides of the one equal to the three sides of the other, each to each, viz. AC=EO, CD=OG, and AD=EG; therefore, these triangles are equal (10, 1), and hence the angle ACD = EOG. Now, if the semicircle ADB be placed upon EGF, because the angle ACD = EOG, it is evident that the radius CD will fall upon the radius OG, and the point D upon G; therefore the arch AMD is equal to the arch ENG.

Theorem V.—In the same circle, or in equal circles, the greater arch is subtended by the greater chord; and, conversely (if the arch be less than half the circumference), the greater chord subtends the greater arch. (Fig. 45.)

For let the arch AH be greater than AD, and let the chords AD, AH, and the radii CD, CH, be drawn. The two sides AC, CH, of the triangle ACH, are equal to the two sides AC, CD of the triangle ACD; and the angle ACH is greater than ACD; therefore the third side AH is greater than the third side AD (9, 1), therefore the chord which subtends the greater arch is the greater. Conversely, if the chord AH be greater than AD, it may be inferred (Cor. 9, 1) from the same triangles, that the angle ACH is greater than ACD, and that thus the arch AH is greater than AD.

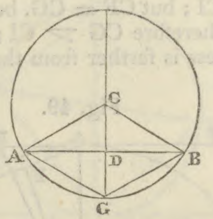
Note. Each of the arches is here supposed less than half the circumference; if they were greater, the contrary property would have place, the arch increasing as the chord diminishes.

Theorem VI.—The radius CG, perpendicular to a chord AB, bisects the chord (or divides it into two equal parts); it also bisects the arch AGB subtended by the chord.

Draw the radii CA, CB; these radii are two equal oblique lines in respect of the perpendicular CD, therefore they are equally distant from the perpendicular (15, 1), that is, AD = DB.

In the next place, because CG is perpendicular to the middle of AB, every point in CG is at equal distances from A and B (16, 1), therefore, if GA, GB be drawn, these lines are equal, and as they are the chords of the arches AG, BG, the arches are also equal (4).

Fig. 46.

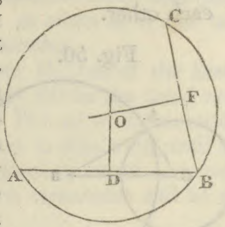


Scholium. Since C the centre, D the middle of the chord AB, and G the middle of the arch subtended by that chord, are three points situated in the same straight line perpendicular to that chord; and that two points in a straight line are sufficient to determine its position; it follows that a straight line which passes through any two of these points must necessarily pass through the third, and must be perpendicular to the chord. It also follows, that a perpendicular to the middle of a chord passes through the centre, and the middle of the arch subtended by that chord.

Theorem VII.—If three points A, B, C be taken in the circumference of a circle; no other circumference which does not coincide with the former can be made to pass through the same three points.

Let the chords AB, BC be drawn, and let OD, OF be drawn from the centre, perpendicular to, and consequently bisecting these chords. The centre of every circle passing through A and B, must necessarily be somewhere in the perpendicular DO (last theor.), and in like manner the centre of every circle passing through B and C must be somewhere in the perpendicular OF; therefore the centre of a circle passing through A, B, and C, must be in the intersection of the perpendiculars DO, FO, and consequently can only be at one and the same point O;

Fig. 47.

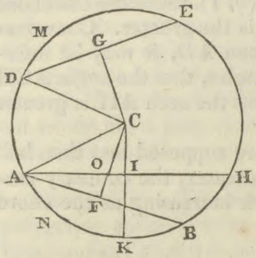


therefore, only one circle can be made to pass through the same three points A, B, C.

Cor. One circumference of a circle cannot intersect another in more than two points; for if they could have three common points, they would have the same centre, and consequently would coincide with each other.

Theorem VIII.—Two equal chords are equally distant from the centre; and of unequal chords, the less is farther from the centre.

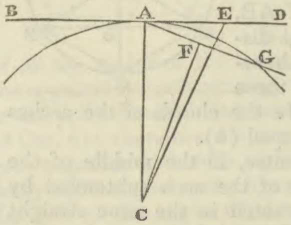
Fig. 48.



Let the chord AB = DE; suppose the chords bisected by the perpendiculars CF, CG from the centre, and draw the radii CA, CD. The right angled triangles CAF, CDG have equal hypothenuses CA, CD; the side AF ($=\frac{1}{2}$ AB) of the one is also equal to the side DG ($=\frac{1}{2}$ DE) of the other, therefore, their remaining sides CF, CG (which are the distances of the chords from the centre) are equal (17, 1).

Next, let the chord AH be greater than DE; the arch AKH shall be greater than DME; upon the arch AKH take ANB equal to DME, draw the chord AB, and suppose COF drawn from the centre perpendicular to AB, and CI perpendicular to AH. It is evident that CF > CO, and (15, 1) CO > CI; much more then is CF > CI; but CF = CG, because the chords AB, DE are equal; therefore CG > CI; that is, of the unequal chords, the less is farther from the centre.

Fig. 49.



Theorem IX.—The perpendicular BD, drawn at the extremity of a radius CA, is a tangent to the circle.

For any oblique line CE is greater than the perpendicular CA (15, 1), therefore the point E is without the circle; therefore the line BD has but one point A common with the circumference, and consequently it is a tangent to the circle. (Def. 8.)

Scholium. Through the same point A, only one tangent, AD, can be drawn to the circle. For if it be possible to draw another, let AG be that other tangent; draw CF perpendicular to AG; then CF shall be less than CA (15, 1), therefore F must be within the circle; and consequently AF when produced must necessarily meet the circle in another point besides A; therefore it cannot be a tangent.

Theorem X.—If BC, the distance of the centres of two circles, be less than the sum of their radii, and also the greater radius less than the sum of the distance of their centres and the lesser radius, the two circles intersect each other.

Fig. 50.

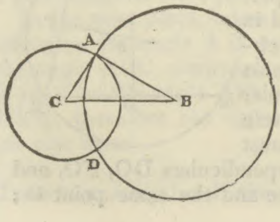


Fig. 51.

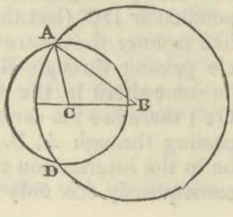
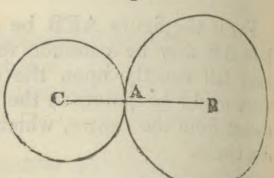


For, that the circles may intersect each other in a point A, it is necessary that the triangle ABC be possible; therefore, not only must CB be less than CA + AB, but also the greater radius AB must be less than AC + CB (7, 1); and it is evident, that as often as the triangle ABC can be constructed, the circumferences described on the centres B, C, shall intersect each other in two points A, D.

Theorem XI.—If the distance CB of the centres of two circles be equal to the sum of the radii CA, BA; the circles shall touch each other externally.

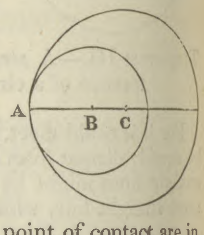
Fig. 52.



It is evident that they have a common point A; but they cannot have more; for if they had two, then the distance of the centres must necessarily be less than the sum of the radii.

Theorem XII.—If the distance CB of the centres of two circles be equal to the difference of the radii; the two circles shall touch each other internally.

Fig. 53.

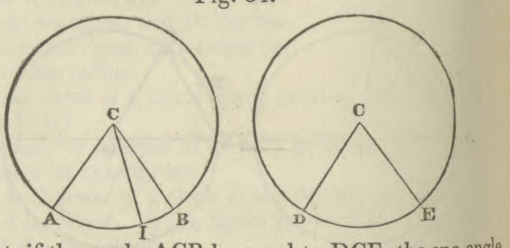


In the first place, it is evident that the point A is common to them both; they cannot, however, have another; for that this may happen, it is necessary that the greater radius AB be smaller than the sum of the radius AC and the distance CB of the centre (10), which is not the case.

Cor. Therefore, if two circles touch each other, either internally or externally, their centres and the point of contact are in the same straight line.

Theorem XIII.—In the same circle, or in equal circles, equal angles ACB, DCE, at the centres, intercept upon the circumference equal arches AB, DE. And, conversely, if the arches AB, DE be equal, the angles ACB, DCE are equal.

Fig. 54.



First, if the angle ACB be equal to DCE, the one angle may be applied upon the other; and as the lines containing them are equal, it is manifest that the point A will fall upon D, and the point B upon E; thus the arch AB will coincide with and be equal to the arch DE.

Next, if the arch AB be equal to DE; the angle ACB is equal to DCE: for if the angles are not equal, let ACB be the greater, and let ACI be taken equal to DCE; then, by what has been already demonstrated, the arch AI = DE; but by hypothesis AB = DE; therefore, AI = AB, which is impossible; therefore the angle ACB = DCE.

Theorem XIV.—The angle BCD at the centre of a circle is double the angle BAD at the circumference, when both stand on the same arch BD.

First, let the centre of the circle be within the angle

BD ; draw the diameter AE. The exterior angle BCE o he triangle BCA is equal to both the inward and oppo si angles BAC, CBA (23, 1); but the triangle BCA bein isosceles, the angle BAC = CBA ; therefore the angle BE is double of the angle BAC. For the same reason, th angle DCE is double of the angle DAE ; therefore the wole angle BCD is double of the whole angle BAD.

Fig. 55.

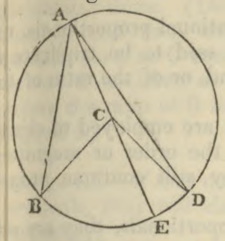


Fig. 56.

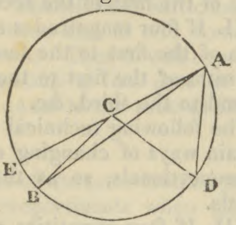

uppose, in the next place, that the centre is without the anle BAD ; then, drawing the diameter AE, it may be donstrated, as in the first case, that the angle ECD is dble of the angle EAD, and that the angle ECB, a part ofhe first, is double the angle EAB, a part of the other ; trefore the remaining angle BCD is double the remainin angle BAD.

TEOREM XV.—All angles BAD, BFD in the same segment BAFD of a circle are equal to one another.

Fig. 57.

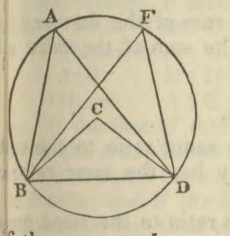

Fig. 58.

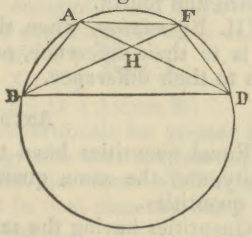


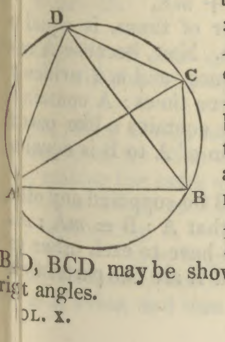
f the segment be greater than a semicircle, from the cetre C draw CB and CD ; then the angles BAD and BD being (by last theorem) each equal to half BCD, th must be equal to one another.

ut if the segment BAFD be less than a semicircle, let He the intersection of BF and AD ; then, the triangles AH and FDH having the angle AHB of the one equal toHD of the other (4, 1), and ABH = FDH (by case 1 will have the remaining angle of the one equal to the reaining angle of the other ; that is, the angle BAH = HFD, or BAD = BFD.

TEOREM XVI.—The opposite angles of any quadrilateral gure ABCD described in a circle are together equal two right angles.

raw the diagonals AC, BD ; because the angle ABD = ACD, and CBD = CAD (last theor.), the sum ABD + CBD = ACD + CAD ; or ABC = ACD + CAD ; to each of these equals add ADC, and ABC + ADC = ACD + CAD + ADC ; but the last three angles being the angles of the triangle ADC, are taken together equal to two right angles (24, 1), therefore ABC + ADC = two right angles. In the same manner the angles BD, BCD may be shown to be together equal to two rit angles.

Fig. 59.

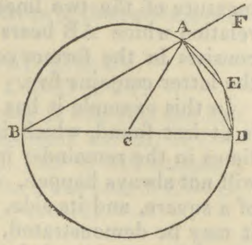


Lines and Figures upon a Plane.

THEOREM XVII.—In a circle, the angle BAD in a semicircle is a right angle, but the angle ABD in a segment greater than a semicircle is less than a right angle ; and the angle AED in a segment less than a semicircle is greater than a right angle.

Let C be the centre, join CA, and produce BA to F. Because CB = CA, the angle CAB = CBA (11, 1) ; and because CD = CA, the angle CAD = CDA, therefore, the whole angle BAD = CBA + CDA ; but these two last angles are together equal to DAF (23, 1), therefore the angle BAD = DAF ; and hence each of them is a right angle.

Fig. 60.



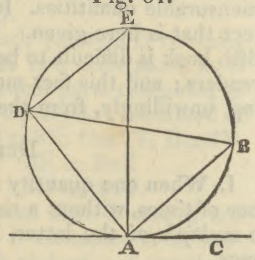
And because ABD + ADB is a right angle, therefore ABD, an angle in a segment greater than a semicircle, is less than a right angle.

And because ABDE is a quadrilateral in a circle, the opposite angles B and E are equal to two right angles (last theor.), but B is less than a right angle ; therefore the angle E, which is in a segment less than a semicircle, is greater than a right angle.

THEOREM XVIII.—The angle BAC contained by AC, a tangent, and AB, a chord drawn from the point of contact, is equal to any angle ADB in the alternate segment of the circle.

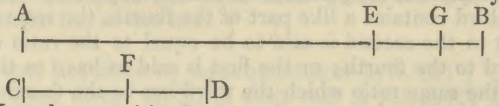
Draw the diameter AE, and join DE. The angles EAC, EDA, being right angles (last theor.), are equal to one another ; and of these, EAB, a part of the one, is equal to EDB, a part of the other (15), therefore the remainder, BAC, of the former is equal to the remainder, BDA, of the latter.

Fig. 61.



SECT. III.—OF PROPORTION.

In comparing two quantities of the same kind, in respect of magnitude, we are led to consider how often the one quantity contains either the whole or some part of the other quantity. To resolve this question, we must find a *common measure* of the quantities ; that is, a quantity that is contained in each a certain number of times exactly.



Let the quantities be two given straight lines AB, CD ; their common measure (if they have one) may be found by proceeding as follows :

Take the less line CD out of the greater AB, as often as possible, and let BE be the remainder. Next take the remainder BE out of the line CD, as often as it can be had, and let DF be the second remainder.

Again, take the second remainder DF out of the first BE, as often as it can be had, and let BG be the third remainder. Take the third remainder BG out of the second DF as often as possible, and proceed in this way, until a remainder be found, which is contained an exact number of times in the preceding. This last remainder will be a common measure of the two lines.

For example, let CD be contained twice in AB, with the remainder BE ; and BE once in CD, with a remainder DF; and DF once in BE, with a remainder BG, and let BG be contained twice exactly in DF; then

$$DF = 2\,BG$$
$$EB = DF + BG = 3\,BG$$
$$CD = EB + DF = 5\,BG$$
$$AB = 2\,CD + EB = 13\,BG.$$

Thus it appears, that BG is contained thirteen times in AB, and five times in CD; therefore BG is a common measure of the two lines. Hence also we see, that the relation which AB bears to CD, in regard to magnitude, consists in the former containing thirteen such parts as the latter contains five.

In this example it has been supposed that a remainder is at last found, which is contained an exact number of times in the remainder immediately preceding. But this will not always happen. If the given lines be the diagonal of a square, and its side, and in innumerable other cases, it may be demonstrated, that no one of the succeeding remainders can be contained an exact number of times in that before it: therefore such quantities cannot have a common measure. Hence quantities are distinguished into two kinds, viz. such as admit of a common measure, and such as do not admit of a common measure. The former are said to be *commensurable*, and the latter *incommensurable.*

The doctrine of proportion, as delivered in the 5th book of Euclid's Elements, applies alike to commensurable and incommensurable quantities; the theory may, however, be rendered considerably easier, by confining it to commensurable quantities. It is this limited view of the subject that is here given. Experience proves that Euclid's fifth book is difficult to be understood by the generality of readers; and this fact may serve as an excuse for deviating, unwillingly, from the illustrious ancient.

Definitions.

I. When one quantity contains another a certain number of times, without a remainder, the former is said to be a *multiple* of the latter, and the latter a *part* of the former.

II. When several quantities are multiples of as many others, and each contains its part the same number of times, the former are called *equimultiples* of the latter, and the latter *like parts* of the former.

III. Between any two finite magnitudes of the same kind there subsists a certain relation, in respect of quantity, which is called their *ratio.* The two magnitudes compared are called the *terms* of the ratio. The first the *antecedent*, and the last the *consequent.*

IV. If there be four quantities, and if the first contain a part of the second (without a remainder) just as often as the third contains a like part of the fourth, the ratio of the first to the second is said to be equal to the ratio of the third to the fourth; or the first is said to have to the second the same ratio which the third has to the fourth.

V. The terms of any number of equal ratios are called *proportionals.*

> *Note.* When four quantities A, B, C, D, are proportionals, it is usual to say, that A is to B, as C to D, and to write them thus, A : B : : C : D; or thus, A : B = C : D.

VI. Quantities are said to be continual proportionals when the ratio of the first to the second, of the second to the third, of the third to the fourth, and so on, are all equal.

VII. When three quantities are continual proportionals, the second is said to be a mean proportional between the other two.

VIII. In proportionals, the antecedent terms are called homologous to one another; as also the consequents to one another.

IX. When there is any number of quantities of the same kind, the first is said to have to the last the ratio compounded of the ratio which the first has to the second, and of the ratio which the second has to the third, and of the ratio which the third has to the fourth, and so on, to the last magnitude.

X. If three magnitudes are continual proportionals, the ratio of the first to the third is said to be duplicate of the ratio of the first to the second.

XI. If four magnitudes are continual proportionals, the ratio of the first to the fourth is said to be triplicate of the ratio of the first to the second, or of the ratio of the second to the third, &c.

The following technical words are employed to signify certain ways of changing either the order or magnitude of proportionals, so as that they still continue proportionals.

XII. If four quantities are proportionals, they are said to be proportionals *by inversion*, when it is inferred that the second is to the first, as the fourth to the third.

XIII. They are proportionals by *alternation*, when the first is to the third, as the second to the fourth.

XIV. By *composition*, when the sum of the first and second is to the second, as the sum of the third and fourth to the fourth.

XV. By *division*, when the difference of the first and second is to the second, as the difference of the third and fourth to the fourth.

XVI. By *conversion*, when the first is to the difference of the first and second, as the third to the difference of the third and fourth.

XVII. By *mixing*, when the sum of the first and second is to their difference, as the sum of the third and fourth to their difference.

Axioms.

1. Equal quantities have the same ratio to the same quantity, and the same quantity has the same ratio to equal quantities.

2. Quantities having the same ratio to the same quantity, or to equal quantities, are equal among themselves; and those to which the same quantity has the same ratio are equal to one another.

3. Ratios equal to one and the same ratio are also equal one to the other.

Theorem I.—Quantities have to one another the same ratio which their equimultiples have.

Let A and B be two quantities, and supposing m to denote any number, let mA and mB (that is, m times A and m times B) be any equimultiples of these quantities; the ratio of A to B is equal to the ratio of mA to mB; or $A : B = mA : mB$.

For, let A contain three such parts, each equal to X, as B contains four, so that

$$A = X + X + X;\ B = X + X + X + X.$$

Then $mA = mX + mX + mX$,

$$mB = mX + mX + mX + mX,$$

because a whole taken any number of times, is equal to the sum of its parts taken as often. Now, because A contains the one fourth of B three times, and mA evidently contains one fourth of mB also three times; A contains a part of B exactly as often as mA contains a like part of mB. Therefore (Def. 4), the ratio of A to B is equal to the ratio of mA to mB.

In the same manner, if A and B be supposed any other multiples of X, it may be proved that $A : B = mA : mB$.

Cor. Like parts of magnitudes have to each other, the same ratio as the whole; for A and B are like parts of mA and mB.

Lines and Figures upon a Plane.

Theorem II.—If four quantities be proportionals, they are proportionals also when taken inversely.

Let A, B, C, D be four quantities, such, that $A : B = C : D$; then $B : A = D : C$.

For, suppose that C contains two such equal parts as D contains three, then, because the ratio of A to B is equal to the ratio of C to D, A will contain two such parts as B contains three. (Def. 4.) Therefore B will contain three such parts as A contains two; and D will contain three such parts as C contains two. Thus B will contain a part of A as often as D contains a like part of C; therefore the ratio of B to A is equal to the ratio of D to C. (Def. 4.)

Theorem III.—If four quantities of the same kind be proportionals, they will also be proportionals when taken alternately.

Let $A : B = C : D$, then, if the quantities be all of the same kind, $A : C = B : D$.

For, let C contain three such parts as D contains four; then (Def. 4) A will contain three such parts as B contains four. Let each of the equal parts contained in A and B be X, and let each of the equal parts contained in C and D be Y; then

$$A = 3X \qquad B = 4X$$
$$C = 3Y \qquad D = 4Y.$$

And because A and C contain X and Y the same number of times, A and C are equimultiples of X and Y. (Def. 2.) Also, because B and D contain X and Y the same number of times, B and D are equimultiples of X and Y.

$$\left.\begin{array}{ll}\text{Therefore} & A : C = X : Y \\ \text{And} & B : D = X : Y\end{array}\right\} \text{Prop. I.}$$
$$\text{Hence} \quad A : C = B : D \quad \text{(Axiom 3.)}$$

Cor. If the first of four proportionals be greater than the third, the second shall be greater than the fourth; and if the first be equal to the third, the second shall be equal to the fourth; and if the first be less than the third, the second shall be less than the fourth.

Theorem IV.—If four quantities be proportionals, they shall also be proportionals by composition.

Let $A : B = C : D$; then, by composition, $A + B : B = C + D : D$.

Let C contain five such parts as D contains three, then (Def. 4) A will contain five such parts as B contains three. Let each of the equal parts contained in A and B be X, and let each of the equal parts contained in C and D be Y. Then, because

$$A = 5X,\ B = 3X,\ C = 5Y,\ D = 3Y,$$

by adding, $A + B = 8X$, and $C + D = 8Y$.

Now, $B = 3X$, and $D = 3Y$;

Therefore $A + B$ contains one third of B eight times, and $C + D$ contains one third of D also eight times, and, in general, $A + B$ will contain a part of B as often as $C + D$ contains a like part of D; therefore (Def. 4) $A + B : B = C + D : D$.

Theorem V.—If four quantities be proportionals, they will also be proportionals by division.

Let $A : B = C : D$, and let A be greater than B, and C greater than D; then $A - B : B = C - D : D$.

For, making the same supposition as in last proposition, so that $A = 5X$, $B = 3X$, $C = 5Y$, $D = 3Y$,

by subtracting, $A - B = 2X$, and $C - D = 2Y$.

Now, $B = 3X$, $D = 3Y$.

Thus it appears, that in this case $A - B$ contains one third of B twice, and that $C - D$ contains one third of D also twice; and, in general, that $A - B$ will always contain some part of B as often as $C - D$ contains a like part of D; therefore (Def. 4) $A - B : B = C - D : D$.

Theorem VI.—If four quantities be proportionals, they shall also be proportionals by conversion.

Let $A : B = C : D$; then $A : A - B = C : C - D$.

For, making the same supposition as in the two last propositions, because

$$A = 5X,\ B = 3X,\ C = 5Y,\ D = 3Y,$$
$$\text{therefore } A - B = 2X,\ C - D = 2Y.$$

Hence it appears, that in this case A contains the half of $A - B$ five times, and that C contains the half of $C - D$ also five times; and, in general, that A will contain a part of $A - B$ as often as C contains a like part of $C - D$; therefore (Def. 4) $A : A - B = C : C - D$.

Theorem VII.—If the first of four magnitudes has the same ratio to the second which the third has to the fourth, and if any equimultiples whatever be taken of the first and third, and any whatever of the second and fourth; the multiple of the first shall have the same ratio to the multiple of the second that the multiple of the third has to the multiple of the fourth.

Let $A : B = C : D$, and supposing m and n to denote any two numbers, let the antecedents A and C be taken each m times, and let the consequents B and D be taken each n times; $mA : nB = mC : nD$.

Suppose that C contains two such parts as D contains three, then (Def. 4) A will contain two such parts as B contains three. Let each of the equal parts contained in A and B be X, and let each of the equal parts contained in C and D be Y, so that $A = 2X$, $B = 3X$, $C = 2Y$, $D = 3Y$.

$$\text{Then } mA = 2mX \qquad nB = 3nX$$
$$mC = 2mY \qquad nD = 3nY.$$

From these expressions, it appears that X and Y are like parts of nB and nD; for each is contained in its multiple three n times; also, that mA and mC are equimultiples of X and Y; for each contains its part two m times. Therefore mA contains a part of nB, exactly as often as mC contains a like part of nD; and hence (Def. 4) $mA : nB = mC : nD$.

Cor. If $A : B = C : D$, then $mA : B = mC : D$, and $A : nB = C : nD$.

Theorem VIII.—If there be any number of quantities, and as many others, which, taken two and two in order, have the same ratio; the first will have to the last of the first quantities the same ratio which the first of the others has to the last.

A, B, C,
H, K, L.

First, Let there be three quantities, A, B, C, and other three, H, K, L, such that $A : B = H : K$, and $B : C = K : L$; then $A : C = H : L$.

For, suppose that H contains two such parts as K contains three and L seven, then (Def. 4) A will contain two such parts as B contains three, and C seven.

Let the equal parts contained in A, B, C be X, and let the equal parts contained in H, K, L be Y, so that

$$A = 2X,\ B = 3X,\ C = 7X,$$
$$H = 2Y,\ K = 3Y,\ L = 7Y.$$

In this case, A contains one seventh of C twice, and H contains one seventh of L also twice; and, in general, A will contain a part of C as often as H contains the same part of L; therefore $A : C = H : L$ (Def. 4).

A, B, C, D,
H, K, L, M.

Next, let there be four quantities A, B, C, D, and other four H, K, L, M, such that $A : B = H : K$, and $B : C = K : L$, and $C : D = L : M$; then $A : D = H : M$.

For, since A, B, C are three quantities, and H, K, L other three quantities, which, taken two and two, have the same ratio; by the foregoing case, $A : C = H : L$. And because $A : C = H : L$, and $C : D = L : M$; therefore, by that same case, $A : D = H : M$. In the same way, the demonstration may be extended to any number of quantities.

Note. This proposition is usually cited by the words *ex æquali* or *ex æquo*.

Theorem IX.—If there be any number of quantities, and as many others, which, taken two and two, in a cross order, have the same ratio; the first will have to the last of the first quantities, the same ratio which the first of the others has to the last.

First, let there be three quantities A, B, C, and other three H, K, L, such that $A : B = K : L$, and $B : C = H : K$; then $A : C = H : L$.

A, B, C,
H, K, L.

For, suppose K to contain two such equal parts as L contains three, then A will contain two such parts as B contains three. (Def. 4.) Let each of the equal parts contained in A and B be X, and let each of the equal parts contained in K and L be Y, so that

$$A = 2X,\ B = 3X,\ K = 2Y,\ L = 3Y.$$

Also, let Z be the same part of C that Y is of L, and let V be the same part of H that X is of A; so that, in this case,

$$C = 3Z,\ H = 2V.$$

Then, because $B : C = H : K$; that is, $3X : 3Z = 2V : 2Y$, and (by Prop. I.) $3X : 3Z = X : Z$, and $2V : 2Y = V : Y$; therefore $X : Z = V : Y$ (Ax. 3). Hence (by Prop. VII.) $2X : 3Z = 2V : 3Y$; but $2X = A$, $3Z = C$, $2V = H$, $3Y = L$; therefore $A : C = H : L$.

Next, let there be four quantities, A, B, C, D, and other four H, K, L, M, such that $A : B : L : M$, and $B : C = K : L$; and $C : D = H : K$; then $A : D = H : M$. For since A, B, C are three quantities, and K, L, M other three, which, taken two and two in a cross order, have the same ratio; by the first case, $A : C = K : M$; but $C : D = H : K$; therefore, again, by the first case, $A : D = H : M$. In the same manner, the demonstration may be extended to any number of quantities.

A, B, C, D,
H, K, L, M.

Note. This proposition is usually cited by the words *ex æquali in proportione perturbata*, or *ex æquo* inversely.

Theorem X.—If the first has to the second the same ratio which the third has to the fourth, and the fifth to the second the same ratio which the sixth has to the fourth; the first and fifth together shall have to the second the same ratio which the third and sixth have to the fourth.

Let $A : B = C : D$,
and $E : B = F : D$;
then $A + E : B = C + F : D$.

Because $E : B = F : D$, by inversion, $B : E = D : F$ (2); but, by hypothesis, $A : B = C : D$; therefore *ex æquali* (Prop. VIII.), $A : E = C : F$; and, by composition, $A + E : E = C + F : F$. Again, by hypothesis, $E : B = F : D$, therefore *ex æq.* $A + E : B = C + D : F$.

Theorem XI.—If four quantities be proportionals, the sum of the first two is to their difference as the sum of the other two to their difference.

Let $A : B = C : D$; then, if A be greater than B, $A + B : A - B = C + D : C - D$.

For, since $A : B = C : D$,
by division (5) $A - B : B = C - D : D$,
and inversion (2) $B : A - B = D : C - D$,
and by composition (4) $A + B : B = C + D : D$,
therefore, *ex æq.* $A + B : A - B = C + D : C - D$.

In like manner, if B be greater than A, it may be proved that $A + B : B - A = C + D : D - C$.

Theorem XII.—If any number of quantities be proportionals; as one of the antecedents is to its consequent, so is the sum of all the antecedents to the sum of all the consequents.

Let $A : B = C : D = E : F$; then $A : B = A + C + E : B + D + F$. For, suppose that A contains two such parts, each $= X$, as B contains three, and that C contains two such parts, each $= Y$, as D contains three, and that E contains two such parts, each $= Z$, as F contains three, and so on; then

$$A = 2X \qquad B = 3X$$
$$C = 2Y \qquad D = 3Y$$
$$E = 2Z \qquad F = 3Z.$$

Hence, by addition,

$A + C + E = 2X + 2Y + 2Z = 2(X + Y + Z)$; $B + D + F = 3X + 3Y + 3Z = 3(X + Y + Z)$.

Thus it appears that A contains one third of B twice, and that $A + C + E$ contains one third of $B + D + F$ also twice; and, in general, that A will contain a part of B just as often as $A + C + E$ contains a like part of $B + D + F$; therefore $A : B = A + C + E : B + D + F$.

In treating of proportion, we have supposed that the antecedent contains some part of the consequent a certain number of times exactly, which part is therefore a common measure of the antecedent and consequent. But there are quantities which cannot have a common measure, and which are therefore said to be *incommensurable*; such, for example, are the sides of two squares one of which has its surface double that of the other.

Although the ratio of two incommensurable quantities cannot be expressed in numbers, yet we can always assign a ratio in numbers which shall be as near to that ratio as we please. For let A and B be any two quantities whatever, and suppose that x is such a part of A that $A = px$; then if q denote the number of times that x can be taken from B, and d the remainder, we have $B = qx + d$, and $qx = B - d$; and because $p : q = px : qx$, therefore $p : q = A : B - d$. Now, as d is less than x, by taking x sufficiently small, d may be less than any proposed quantity; so that $B - d$ may differ from B by less than any given quantity; therefore two numbers p and q may always be assigned, such, that the ratio of p to q shall be the same as the ratio of A to a quantity that differs less from B than by any given quantity, however small that quantity may be.

Hence we may conclude, that whatever has been delivered in this section relating to commensurable quantities, may be considered as applying equally to such as are incommensurable.

SECT. IV.—THE PROPORTIONS OF FIGURES.

Definitions.

I. *Equivalent Figures* are such as have equal surfaces.

Two figures may be equivalent, although very dissimilar; thus a circle may be equivalent to a square, a triangle to a rectangle, and so of other figures.

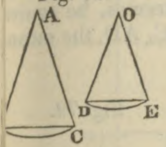
We shall give the denomination of *equal* figures to those which, being applied the one upon the other, coincide entirely: thus, two circles having the same radius are equal; and two triangles having three sides of the one equal to three sides of the other, each to each, are also equal.

Lines and Figures upon a Plane.

II. Two figures are *similar*, when the angles of the one re equal to the angles of the other, each to each; and ne *homologous* sides proportionals. The homologous sides re those which have the same position in the two figures; r which are adjacent to the equal angles. The angles hemselves are called *homologous angles*.

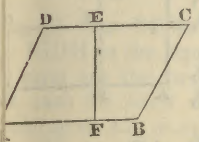
Two equal figures are always similar, but similar figures may be very unequal.

Fig. 62.



III. In two different circles, *similar sectors, similar arches, similar segments*, are such as correspond to equal angles at the centre. Thus the angle A being equal to the angle O, the arch BC is similar to the arch DE, and the sector ABC to the sector ODE, &c.

Fig. 63.



IV. The *Altitude of a parallelogram* is the perpendicular which measures the distance between the opposite sides or bases AB, CD.

V. The *Altitude of a triangle* is the perpendicular AD drawn from the vertical angle A upon the base BC.

Fig. 64.

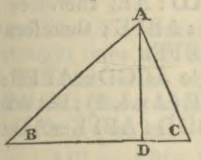


Fig. 65.

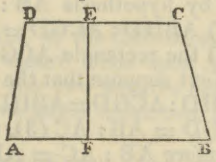


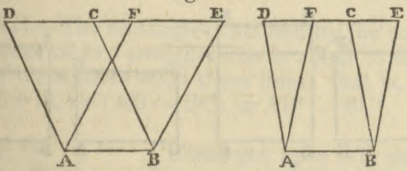
VI. The *Altitude of a trapezoid* is the perpendicular EF rawn between its two parallel bases AB, CD.

VII. The *Area* and the surface of a figure are terms of early the same signification. The term *area*, however, is nore particularly used to denote the superficial quantity of he figure in respect of its being measured, or compared ith other surfaces.

HEOREM I.—Parallelograms which have equal bases and equal altitudes are equivalent.

Let AB be the common base of the parallelograms ABCD, EBAF, which being supposed to have the same ltitude, the sides DC, FE opposite to the bases will lie n DE a line parallel to AB. Now, from the nature of a arallelogram, AD = BC, and AF = BE; for the same eason DC = AB, and FE = AB; therefore DC = FE, nd taking away DC and FE from the same line DE, the emainders CE and DF are equal; hence the triangles DAF, CBE have three sides of the one equal to three ides of the other, each to each; and consequently are qual (10, 1). Now, if from the quadrilateral ABED the riangle ADF be taken away, there will remain the parallelogram ABEF; and if from the same quadrilateral ABED, the triangle CBE, equal to the former, be taken way, there will remain the parallelogram ABCD; therefore the two parallelograms ABCD, ABEF, which have he same base and the same altitude, are equivalent.

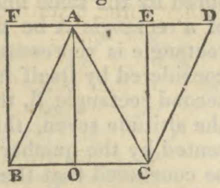
Fig. 66.



Cor. Every parallelogram is equivalent to a rectangle f the same base and altitude.

HEOREM II.—Every triangle ABC is the half of a parallelogram ABCD, having the same base and altitude.

Fig. 67.



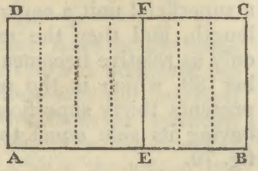
For the triangles ABC, ACD are equal (28, 1).

Cor. 1. Therefore a triangle ABC is the half of a rectangle BCEF of the same base and altitude.

Cor. 2. All triangles having equal bases and equal altitudes are equivalent.

THEOREM III.—Two rectangles of the same altitude are to each other as their bases.

Fig. 68.

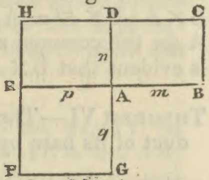


Let ABCD, AEFD be two rectangles, which have a common altitude AD; the rectangle ABCD shall have to the rectangle AEFD the same ratio that the base AB has to the base AE.

Let the base AB have to the base AE the ratio of the number p (which we shall suppose 7) to the number q (which may be 4), that is, let AB contain p (7), such equal parts as AE contains q (4); then, if perpendiculars be drawn to AB and AE at the points of division, the rectangles ABCD and AEFD will be divided, the former into p and the latter into q rectangles, which will be all equal (1); for they have equal bases and the same altitude. Thus the rectangle ABCD will also contain p such equal parts as the rectangle AEFD contains q; therefore the rectangle ABCD is to AEFD as the number p to the number q (Ax. 3, 3), that is, as the base AB to AE.

THEOREM IV.—Any two rectangles are to each other as the products of any numbers proportional to their sides.

Fig. 69.



Let the numbers m, n, p, q have among themselves the same ratios that the sides of the rectangles ABCD, AEFG have to each other; that is, let AB contain m such equal parts, whereof AD contains n; and AE contains p, and AG contains q, then shall ABCD : AEFG $= mn : pq$.

Let the rectangles be so placed that the sides AB, AE may be in a straight line, then AD and AG will also lie in a straight line (3, 1). Now (3)

$$\text{ABCD} : \text{AEHD} = \text{AB} : \text{AE} = m : p,$$

but $m : p = nm : np$ (1, 3),

therefore ABCD : AEHD $= nm : np$.

Again, AEHD : AEFG = AD : AG $= n : q$;

but $n : q = pn : pq$;

therefore AEHD : AEFG $= pn : pq$;

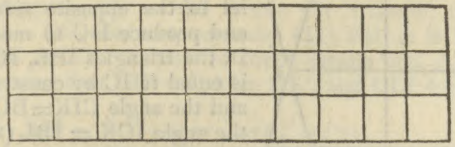
and it was shown that

ABCD : AEHD $= nm : np$ or pn,

therefore (8, 3) ABCD : AEFG $= mn : pq$.

SCHOLIUM.

Fig. 70.



Hence it appears, that the product of the base by the altitude of a rectangle may be taken for its measure, observing that by such product is meant that of the number of linear units in the base by the number of linear units in the altitude. This measure is however not absolute, but relative; for it must be supposed, that in comparing one rectangle with another, the sides of both are measured by the same linear unit. For example, if the base of a rectangle A be three units, and its altitude 10, the rectangle is represented by 3×10, or 30; this number considered by itself has no meaning; but if we have a second rectangle B, the base of which is twelve units and the altitude seven, this second rectangle shall be represented by the number 12×7, or 84; and hence it may be concluded that the two rectangles are to each other as 30 to 84; therefore, if in estimating any superficies the rectangle A be taken for the measuring unit, the rectangle B shall have for its absolute measure $\frac{84}{30}$, that is, it shall be $\frac{84}{30}$ superficial units.

It is more common, as well as more simple, to take for a superficial unit a square, the side of which is an unit in length, and then the measure which we have regarded only as relative becomes absolute: for example, the number 30, which is the measure of the rectangle A, represents thirty superficial units, or thirty squares, each having its side equal to an unit. To illustrate this, see fig. 70.

Theorem V.—The area of any parallelogram is equal to the product of its base by its altitude. (Fig. 67.)

For the parallelogram ABCD is equivalent to the rectangle FBCE, which has the same base BC, and the same altitude AO (Cor. 1); but the measure of the rectangle is BC × AO (Schol. 4), therefore the area of the parallelogram is BC × AO.

Cor. Parallelograms having the same base, or equal bases, are to each other as their altitudes; and parallelograms having the same altitude are to each other as their bases; for in the former case put B for the common base, and A and A′ for the altitudes, then the areas of the figures are B × A and B × A′; and it is manifest that B × A : B × A′ = A : A′; and in the latter case, putting A for the common altitude, and B and B′ for the bases, it is evident that B × A : B′ × A = B : B′.

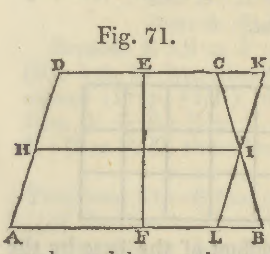
Theorem VI.—The area of a triangle is equal to the product of its base by the half of its altitude. (Fig. 67.)

For the triangle ABC is half of the parallelogram ABCD, which has the same base BC, and the same altitude AO (2); but the area of the parallelogram is BC × AO (5), therefore that of the triangle is $\frac{1}{2}BC \times AO$, or $BC \times \frac{1}{2}AO$.

Cor. Two triangles of the same altitude are to each other as their bases; and two triangles having the same base are to each other as their altitudes.

Theorem VII.—The area of a trapezoid ABCD is equal to the product of its altitude EF by half the sum of its parallel sides AB, CD.

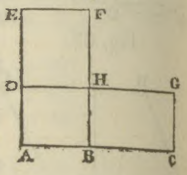
Fig. 71.



Through the point I, the middle of BC, draw KL parallel to the opposite side AD, and produce DC to meet KL. In the triangles IBL, ICK, IB is equal to IC by construction, and the angle CIK = BIL, and the angle ICK = IBL (21, 1); therefore these triangles are equal; and hence the trapezoid ABCD is equivalent to the parallelogram ALKD, and has for its measure AL × EF. But AL = DK, and because the triangle IBL is equal to the triangle KCI, the side BL = CK; therefore AB + CD = AL + DK = 2AL; hence AL is half the sum of the parallel sides AB, CD; and as the area of the trapezoid is equal to FE × AL, it is also equal to $FE \times \left(\frac{AB+CD}{2}\right)$.

Theorem VIII.—If four straight lines AB, AC, AD, AE be proportionals; the rectangle ABFE, contained by the two extremes, is equivalent to the rectangle ACGD contained by the means. And conversely, if the rectangle contained by AB, AE, the extremes, be equivalent to the rectangle contained by AC, AD, the means, the four lines are proportionals.

Fig. 72.



Let the rectangles be so placed as to have the common angle A, and let BF, DG intersect each other in H. Because the rectangles ABHD, ACGD have the same altitude AD,

ABHD : ACGD = AB : AC (3);

and because the rectangles ABHD, ABFE have the same altitude AB, for the same reason,

ABHD : ABFE = AD : AE;

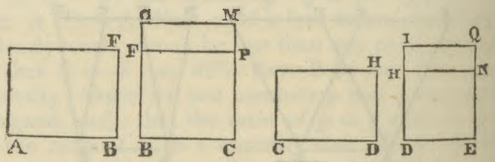
but by hypothesis AB : AC = AD : AE, therefore (Ax. 3, 3) ABHD : ACGD = ABHD : ABFE; therefore (Ax. 2, 3) the rectangle ACGD = ABFE.

Next suppose that the rectangle ACGD = ABFE; then ABHD : ACGD = ABHD : ABFE (Ax. 1, 3); but ABHD : ACGD = AB : AC (3), and ABHD : ABFE = AD : AE; therefore AB : AC = AD : AE.

Cor. If three straight lines be proportionals, the rectangle contained by the extremes is equal to the square of the mean; and if the rectangle contained by the extremes be equal to the square of the mean, the three straight lines are proportionals.

Theorem IX.—If four straight lines be proportionals, and also other four; the rectangles contained by the corresponding terms shall be proportionals; that is, if AB : BC = CD : DE, and BF : BG = DH : DI, then shall rectangle AF : rect. BM = rect. CH : rect. DQ.

Fig. 73.



For in BG and DI produced, if necessary, take BF = BF, and DH = DH, and let FP be parallel to BC, and HN to DE; then (3),

rect. AF : rect. BP = AB : BC,
and rect. CH : rect. DN = CD : DE;

but AB : BC = CD : DE (by hypothesis), therefore,

rect. AF : rect. BP = rect. CH : rect. DN;

now (3) rect. BP : rect. BM = BF : BG, and rect. DN : rect. DQ = DH : DI; but BF : BG = DH : DI (by hypoth.) therefore,

rect. BP : rect. BM = rect. DN : rect. DQ;

but it has been shown that

rect. AF : rect. BP = rect. CH : rect. DN,

therefore (8, 3),

rect. AF : rect. BM = rect. CH : rect. DQ.

Cor. Hence the squares of four proportional straight lines are themselves proportionals.

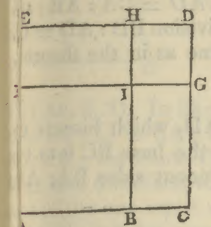
Theorem X.—If a straight line AC be divided into any two parts at B, the square made upon the whole line

Lines and Figures upon a Plane.

AC shall be equal to the squares made upon the two parts AB, BC, together with twice the rectangle contained by these two parts; which may be expressed thus,

$$AC^2 = AB^2 + BC^2 + 2AB \times BC.$$

Fig. 74.



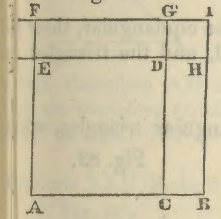
Suppose the square ACDE to be constructed; take AF = AB, draw FG parallel to AC, and BH parallel to CD.

The square ACDE is made up of four parts; the first ABIF is the square upon AB, because AF = AB; the second IGDH is the square upon BC, for AC = AE, and AB = AF; therefore AC — AB = AE — AF, that is, BC = EF; but BC = IG, and EF = DG (26, 1); therefore IGDH is the square upon BC; and the remaining two parts are the two rectangles BCGI, FEHI, which have each for their measure AB × BC; therefore the square upon AC is equal to the squares upon AB and BC, and twice the rectangle AB × BC.

Theorem XI.—If a straight line AC be the difference of two straight lines AB, BC, the square made upon AC shall be equal to the excess of the two squares upon AB and BC above twice the rectangle contained by AB and BC; that is,

$$AC^2 = AB^2 + BC^2 - 2AB \times BC.$$

Fig. 75.

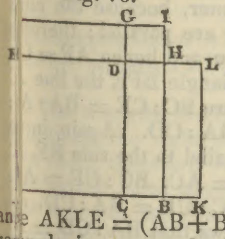


Construct the square ABIF, take AE = AC, and draw CG parallel to BI, and HK parallel to AB; and complete the square EFLK. The two rectangles CBIG, GLKD have each AB × BC for their measure; and if these be taken from the whole figure ABILKEA, that is, from $AB^2 + BC^2$, there will remain the square ACDE, that is, the square upon AC.

Theorem XII.—The rectangle contained by the sum and the difference of two straight lines is equal to the difference of the squares upon those lines; that is,

$$(AB + BC) \times (AB - BC) = AB^2 - BC^2.$$

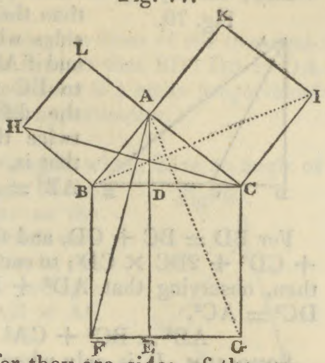
Fig. 76.



Construct upon AB and AC the squares ABIF, ACDE; produce AB, so that BK = BC, and complete the rectangle AKLE. The base AK of the rectangle is the sum of the two lines AB, BC; and its altitude AE is the difference of the same lines; therefore the rectangle AKLE = (AB + BC) (AB — BC); but the same rectangle is composed of two parts ABHE + BHLK, of which BHLK is equal to the rectangle EDGF, for BH = DE and BK = FE; therefore AKLE = ABHE + EDGF; but these two parts constitute the excess of the square ABIF above the square DHIG, the former of which is the square upon AB, and the latter the square upon BC; therefore $(AB + BC) \times (AB - BC) = AB^2 - BC^2$.

Theorem XIII.—The square upon the hypothenuse of a right-angled triangle is equal to the sum of the squares upon the two other sides.

Fig. 77.

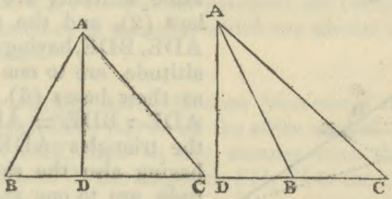


Let ABC be a right-angled triangle; having formed the squares upon its three sides, draw a perpendicular AD from the right angle upon the hypothenuse, and produce it to E, and draw the diagonals AF, CH. The angle ABF is evidently the sum of ABC and a right angle, and the angle HBC is also the sum of ABC and a right angle; therefore the angle ABF = HBC. Now AB = BH, for they are sides of the same square, and BC = BF for the same reason; therefore the triangles ABF, HBC have two sides, and the included angle of the one equal to two sides, and the included angle of the other, each to each, therefore the triangles are equal (5, 1); but the triangle ABF is the half of the rectangle BDEF (which for brevity's sake we shall call BE), because it has the same base BF, and the same altitude BD (2); and the triangle HBC is in like manner half of the square AH; for the angles BAC, BAL being both right angles, CA and AL constitute a straight line parallel to BH (3, 1); and thus the triangle HBC and the square AH have the same base HB, and the same altitude AB; from which it follows that the triangle is half of the square (2). It has now been proved that the triangle ABF is equal to the triangle HBC; and that the rectangle BE is double of the former, and the square AH double of the latter; therefore the rectangle BE is equal to the square AH. It may be demonstrated in like manner that the rectangle CDEG, or CE, is equal to the square AI; but the rectangles BE, CE make up the square BCGF; therefore the square BCGF upon the hypothenuse is equal to the squares ALHB, AKIC upon the other two sides.

Theorem XIV.—In a triangle ABC, if the angle C be acute; the square of the opposite side AB is less than the squares of the sides which contain the angle C; and if AD a perpendicular be drawn to BC from the opposite angle, the difference shall be equal to twice the rectangle BC × CD; that is,

$$AB^2 = AC^2 + CB^2 - 2BC \times CD.$$

Fig. 78.



First, suppose AD to fall within the triangle, then BD = BC — CD, and consequently (11) $BD^2 = BC^2 + CD^2 - 2BC \times CD$; to each of these equals add AD^2; then, observing that $BD^2 + DA^2 = BA^2$, and $CD^2 + DA^2 = CA^2$,

$$AB^2 = BC^2 + CA^2 - 2BC \times CD.$$

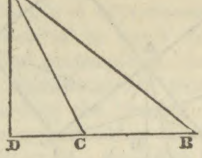
Next, suppose AD to fall without the triangle, so that BD = CD — BC, and therefore $BD^2 = CD^2 + BC^2 - 2BC \times CD$ (11), to each of these add AD^2 as before, and we get

$$AB^2 = BC^2 + CA^2 - 2BC \times CD.$$

Theorem XV.—In a triangle ABC, if the angle C be obtuse; the square of the opposite side AB is greater than the sum of the squares of the sides which contain the angle C; and if AD a perpendicular be drawn to BC from the opposite angle; the difference shall be equal to twice the rectangle BC × CD; that is,

$$AB^2 = AC^2 + BC^2 + 2BC \times CD.$$

Fig. 79.

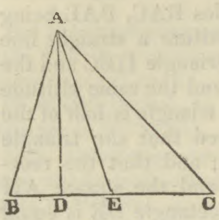


For $BD = BC + CD$, and therefore (10), $BD^2 = BC^2 + CD^2 + 2BC \times CD$; to each of these equals add AD^2, then, observing that $AD^2 + DB^2 = AB^2$, and $AD^2 + DC^2 = AC^2$,

$$AB^2 = BC^2 + CA^2 + 2BC \times CD.$$

Scholium. It is only when a triangle has one of its angles a right angle, that the sum of the squares of two of its sides can be equal to the square of the third side; for if the angle contained by those sides be acute, the sum of their squares is greater than the square of the opposite side, and if the angle be obtuse, that sum is less than the square of the opposite side.

Fig. 80.



Theorem XVI.—If a straight line AE be drawn from the vertex of any triangle ABC to the middle of its base BC; the sum of the squares of the sides is equal to twice the square of half the base, and twice the square of the line drawn from the vertex to the middle of the base; that is, $AB^2 + AC^2 = 2BE^2 + 2AE^2$.

Draw AD perpendicular to BC, then

$$AB^2 = BE^2 + EA^2 - 2BE \times ED \ (14),$$

$$\text{and } AC^2 = CE^2 + EA^2 + 2CE \times ED \ (15);$$

therefore, by adding equals to equals, and observing that $BE = CE$, and therefore $BE^2 = CE^2$, and $2BE \times ED = 2CE \times ED$,

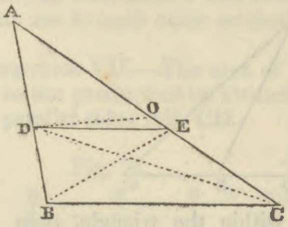
$$AB^2 + AC^2 = 2BE^2 + 2AE^2.$$

Theorem XVII.—A straight line DE drawn parallel to one of the sides of a triangle ABC, divides the other two sides AB, AC proportionally, so that $AD : DB = AE : EC$.

Join BE and CD. The triangles BDE, CDE, having the same base DE, and the same altitude, are equivalent (2), and the triangles ADE, BDE, having the same altitude, are to one another as their bases (6), that is, $ADE : BDE = AD : DB$; the triangles ADE, CDE, having also the same altitude, are to one another as their bases; that is, $ADE : CDE = AE : EC$, but the triangle BDE has been proved equal to CDE; therefore, because of the common ratio in the two proportions, we have (Ax. 3, 3)

$$AD : DB = AE : EC.$$

Fig. 81.



Cor. Hence, by composition, $AB : AD = AC : AE$; and $AB : BD = AC : CE$.

Theorem XVIII.—Conversely, if two of the sides AB, AC of a triangle be divided proportionally by the straight line DE, so that $AD : DB = AE : EC$; then shall the line DE be parallel to the remaining side BC.

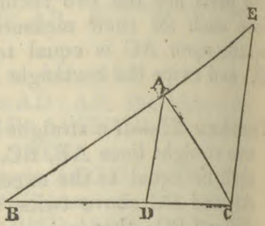
For if DE is not parallel to BC, suppose some other line DO to be parallel to BC; then, $AB : BD = AC : CO$ (17), and since by hypothesis $AD : DB = AE : EC$, and consequently, by composition, $AB : BD = AC : CE$, therefore, $AC : CO = AC : CE$; therefore, $CO = CE$ (2 Ax. 3), which is impossible; therefore DO is not parallel to BC.

Cor. If it be supposed that $BA : AD = CA : AE$; still DE will be parallel to BC; for by division $BD : AD = CE : AE$, this proportion being the same as in the theorem, the conclusion must be the same.

Theorem XIX.—A straight line AD, which bisects the angle BAC of a triangle, divides the base BC into two segments proportional to the adjacent sides BA, AC; that is, $BD : DC = BA : AC$.

Through the point C draw CE parallel to AD, so as to meet BA produced. In the triangle BCE, the line AD is parallel to one of its sides CE, therefore $BD : DC = BA : AE$; now the triangle CAE is isosceles, for, because of the parallels AD, CE, the angle $ACE = DAC$, and the angle $AEC = BAD$, (21, 1); but by hypothesis $DAC = BAD$, therefore $ACE = AEC$; and consequently, $AE = AC$ (12, 1), therefore, substituting AC instead of AE in the above proportion, it becomes $BD : DC = BA : AC$.

Fig. 82.

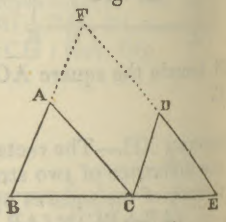


Theorem XX.—If two triangles be equiangular, their homologous sides are proportional, and the triangles are similar.

Let ABC, CDE be two equiangular triangles, which have the angle $BAC = CDE$, $ABC = DCE$, and $ACB = DEC$; the homologous sides, or the sides adjacent to the equal angles, shall be proportional; that is, $BC : CE = AB : CD = AC : DE$.

Place the homologous sides BC, CE in the same direction, and produce the sides BA, ED, till they meet in F. Because BCE is a straight line, and the angle BCA is equal to CED, the lines CA, EF are parallel (22, 1); and in like manner, because the angle $ABC = DCE$, the lines BF, CD are parallel; therefore the figure ACDF is a parallelogram, and hence $AF = CD$, and $CA = DF$ (26, 1). In the triangle BFE the line AC is parallel to the side FE, therefore $BC : CE = BA : AF$; or since $AF = CD$, $BC : CE = BA : CD$. Again, in the same triangle, because CD is parallel to the side BF, $BC : CE = FD : DE$, or, since $FD = AC$, $BC : CE = AC : DE$; having now shown that $BC : CE = BA : CD$, and that $BC : CE = AC : DE$, it follows that $BA : CD = AC : DE$; therefore the equiangular triangles BAC, CDE have their homologous sides proportional, and hence (Def. 2) the triangles are similar.

Fig. 83.



Scholium. It is manifest that the homologous sides are opposite to the equal angles.

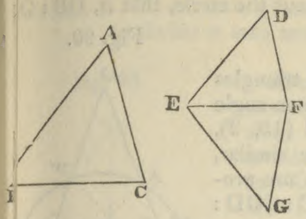
Theorem XXI.—If two triangles have their homologous sides proportional, they are equiangular and similar.

Suppose that $BC : EF = AB : DE = AC : DF$; then shall $A = D$, $B = E$, $C = F$. At the point E make the

Lines and Figures upon a Plane.

nd agle $FEG = B$, and at the point F make $EFG = C$; then the third angle G shall be equal to the third angle A, and the two triangles ABC, GEF shall be equiangular; therefore, by the last theorem, $BC : EF = AB : GE$; but by hypothesis $BC : EF = AB : DE$; therefore GE = D (Ax. 2, 3). In like manner, because by the same theo m $BC : EF = CA : FG$; and by hypothesis BC : EF = C : FD; therefore $FG = FD$; but it was shown that E = ED, therefore, the triangles GEF, DEF, having the si s of the one equal to those of the other, each to each, ar equal; but, by construction, the triangle GEF is equi- a ular to ABC, therefore also the triangles DEF, ABC ar equiangular and similar.

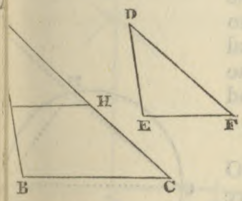
Fig. 84.



T**EOREM XXII.**—Two triangles which have an angle of he one equal to an angle of the other, and the sides bout these angles proportional, are similar.

et the angle $A = D$, and let $AB : DE = AC : DF$, the triangle ABC is similar to DEF. Take $AG = DE$, and draw GH parallel to BC, then the angle $AGH = ABC$ (21, 1), therefore the triangle AGH is equiangular to ABC, and consequently (20) $AB : AG = AC : AH$; but by hypothesis $AB : DE = AC : DF$, and by construction AG = DE, therefore $AH = DF$; the two triangles AGH, D F are therefore equal (5, 1), but the triangle AGH is si lar to ABC, therefore DEF is similar to ABC.

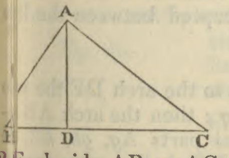
Fig. 85.



T**EOREM XXIII.**—In a right-angled triangle, if a perpendicular AD be drawn from the right angle upon the hypothenuse, then,

1. The triangles ABD, CAD on each side of the perpendicular are similar to the whole triangle BAC, and to one another.
2. ach side AB or AC is a mean proportional between e hypothenuse BC, and the adjacent segment BD or C.
3. he perpendicular AD is a mean proportional between e two segments BD, DC.

Fig. 86.



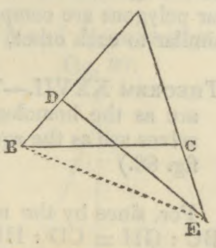
The triangles BAD, BAC have the common angle B besides, the right angle BAC is equal to the right ar e BDA, therefore the third angle BAD of the one is e al to the third angle BCA of the other; therefore, th e triangles are equiangular and similar; and in the sa e manner it may be shown that the triangle DAC is e angular and similar to BAC; therefore the three triar es are equiangular and similar to each other.

Because the triangle BAD is similar to the triangle B C, their homologous sides are proportional. Now the si BD of the lesser triangle is homologous to the side B of the greater, because they are opposite to the equal ar es BAD, BCA; in like manner BA, considered as a si of the lesser triangle, is homologous to the side BC of e greater, each being opposite to a right angle; therefo , $BD : BA = BA : BC$. In the same manner it may be hown that $CD : CA = CA : CB$, therefore each side is a mean proportional between the hypothenuse and the segment adjacent to that side.

3. By comparing the homologous sides of the two similar triangles ABD, ACD, it appears that $BD : DA = DA : DC$; therefore the perpendicular is a mean proportional between the segments of the hypothenuse.

T**HEOREM XXIV.**—Two triangles which have an angle of the one equal to an angle of the other, are to each other as the rectangles of the sides which contain the equal angles; that is, the triangle ABC is to the triangle ADE as the rectangle $AB \times AC$ to the rectangle $AD \times AE$.

Fig. 87.



Join BE; because the triangles ABE, ADE, have a common vertex E, they have the same altitude, therefore $ABE : ADE = AB : AD$ (Cor. to 6); but $AB : AD = AB \times AE : AD \times AE$ (3), therefore,

$$ABE : ADE = AB \times AE : AD \times AE.$$

In the same manner, it may be demonstrated that

$$ABC : ABE = AB \times AC : AB \times AE;$$

therefore (8, 3) $ABC : ADE = AB \times AC : AD \times AE$.

C**OR.** Therefore the two triangles are equivalent, if the rectangle $AB \times AC = AD \times AE$, or (8), if $AB : AD = AE : AC$, in which case the sides about the equal angles are said to be *reciprocally* proportional.

S**CHOLIUM.** What has been proved of triangles is also true of parallelograms, they being the doubles of such triangles.

T**HEOREM XXV.**—Two similar triangles are to each other as the squares of their homologous sides. (See fig. 85.)

Let the angle $A = D$, the angle $B = E$, and therefore the angle $C = F$,

then (20) $AB : DE = AC : DF$;

now $AB : DE = AB : DE$,

for the two ratios are identical, therefore (9),

$$AB^2 : DE^2 = AB \times AC : DE \times DF;$$

but $ABC : DEF = AB \times AC : DE \times DF$ (24),

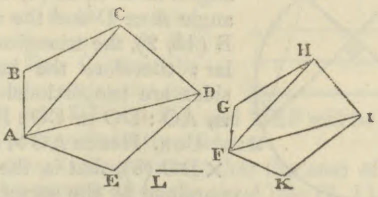
therefore $ABC : DEF = AB^2 : DE^2$ (Ax. 3, 3),

therefore the two similar triangles ABC, DEF are to each other as the squares of the homologous sides AB, DE, or as the squares of any of the other homologous sides.

T**HEOREM XXVI.**—Similar polygons are composed of the same number of triangles which are similar and similarly situated.

In the polygon ABCDE, draw from one of the angles A the diagonals AC, AD to all the other angles. In the polygon FGHIK, draw in like manner from the angle F, homologous to A, the diagonals FH, FI to the other angles.

Fig. 88.



Because the polygons are similar, the angle ABC is equal to its homologous angle FGH (Def. 2), also the sides AB, BC are proportional to FG, GH; so that $AB : FG = BC : GH$, therefore the triangles ABC, FGH are similar (22);

therefore the angle $BCA = GHF$, and these being taken from the equal angles BCD, GHI, the remainders ACD, FHI are equal; but the triangles ABC, FGH being similar, $AC : FH = BC : GH$, besides, because of the similarity of the polygons, $BC : GH = CD : HI$; therefore $AC : FH = CD : HI$; now it has been already shown that the angle $ACD = FHI$, therefore the triangles ACD, FHI are similar (22). It may be demonstrated in the same manner that the remaining triangles are similar, whatever be the number of sides of the polygon; therefore two similar polygons are composed of the same number of triangles similar to each other, and similarly situated.

Theorem XXVII.—The perimeters of similar polygons are as the homologous sides; and the polygons themselves are as the squares of the homologous sides. (See fig. 88.)

For, since by the nature of similar figures $AB : FG = BC : GH = CD : HI$, &c. therefore (12, 3) $AB + BC + CD$, &c. the perimeter of the first figure, is to $FG + GH + HI$, &c. the perimeter of the second, as the side AB to its homologous side FG.

Again, because the triangles ABC, FGH are similar, $ABC : FGH = AC^2 : FH^2$ (25), in like manner $ACD : FHI = AC^2 : FH^2$; therefore,

$$ABC : FGH = ACD : FHI.$$

By the same manner of reasoning,

$$ACD : FHI = ADE : FIK,$$

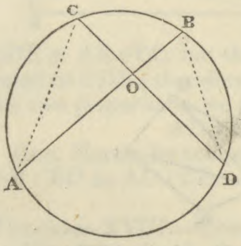
and so on if there be more triangles; hence, from this series of equal ratios, it follows (12, 3) that $ABC + ACD + ADE$, or the polygon ABCDE, is to $FGH + FHI + FIK$, or the polygon FGHIK, as one of the antecedents ABC, is to its consequent FGH, or as AB^2 to FG^2; therefore similar polygons are to each other as the squares of their homologous sides.

Cor. 1. If three similar figures have their homologous sides equal to the three sides of a right-angled triangle, the figure having the greatest side shall be equal to the two others; for these three figures are proportional to the squares of their homologous sides, and the square of the hypothenuse is equal to the squares of the other two sides.

Cor. 2. Similar polygons have to each other the duplicate ratio of their homologous sides. For let L be a third proportional to the homologous sides AB, FG, then (Def. 10, 3) AB has to L the duplicate ratio of AB to FG; but $AB : L = AB^2 : AB \times L$ (3), or since $AB \times L = FG^2$, (Cor. to 8) $AB : L = AB^2 : FG^2 = ABCDE : FGHIK$; therefore the figure ABCDE has to the figure FGHIK, the duplicate ratio of AB to FG.

Theorem XXVIII.—The segments of two chords AB, CD, which cut each other within a circle, are reciprocally proportional, that is, $AO : DO = CO : OB$.

Fig. 89.

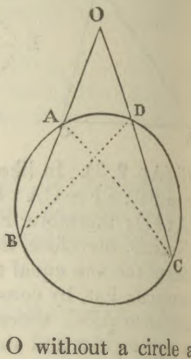


Join AC and BD; and because the triangles AOC, BOD have the angles at O equal (4, 1), and the angle $A = D$ and the angle $C = B$ (15, 2), the triangles are similar; therefore the homologous sides are proportional (20), that is, $AO : DO = CO : BO$.

Cor. Hence $AO \times BO = CO \times DO$ (8), that is, the rectangle contained by the segments of the one chord is equal to the rectangle contained by the segments of the other.

Theorem XXIX.—If from a point O without a circle two straight lines be drawn, terminating in the concave arch BC; the whole lines shall be reciprocally proportional to the parts of them without the circle, that is, $OB : OC = OD : OA$.

Fig. 90.

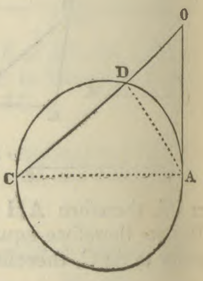


Join AC, BD; then the triangles OAC, OBD have the common angle O, also the angle $B = C$ (15, 2), therefore the triangles are similar, and the homologous sides are proportional, that is, $OB : OC = OD : OA$.

Cor. Therefore (8) $OA \times OB = OC \times OD$, that is, the rectangles contained by the whole lines, and the parts of them without the circle, are equal to one another.

Theorem XXX.—If from a point O without a circle a straight line OA be drawn touching the circle, and also a straight line OC cutting it; the tangent shall be a mean proportional between the whole line which cuts the circle, and the part of it without the circle; that is, $OC : OA = OA : OD$.

Fig. 91.



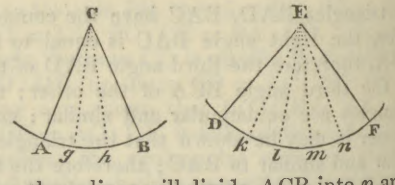
For if AC, AD be joined, the triangles OAD, OCA, have the angle at O common to both, also the angle ACD or ACO equal to DAO (18, 2), therefore the triangles are similar (20), and consequently $CO : OA = OA : OD$.

Cor. Therefore (Cor. to 8) $CO \times OD = OA^2$, that is, the square of the tangent is equal to the rectangle contained by the whole line which cuts the circle, and the part of it without the circle.

Theorem XXXI.—In the same circle, or in equal circles, any angles ACB, DEF are to each other as the arches AB, DF of the circles intercepted between the lines which contain the angles.

Suppose the arch AB to have to the arch DF the ratio of the number p to the number q; then the arch AB being supposed divided into equal parts Ag, gh, hB, the number of which is p, the arch DF shall contain q equal parts Dk, kl, lm, mn, nF, each of which is equal to any one of the equal parts into which AB is divided. Draw straight lines from the centres of the circles to the points of division; these lines will divide ACB into p angles and DEF into q angles, which are all equal (13, 2); therefore the angle ACB has to the angle DEF the ratio of the number p to the number q, which ratio is the same as that of the arch AB to the arch DF.

Fig. 92.



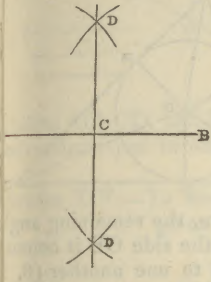
Cor. Hence it appears that angles may be measured and compared with each other by means of arches of circles described on the vertices of the angles as centres; observing, however, that the radii of the circles must be equal.

Lines and Figures upon a Plane.

SECT. V.—PROBLEMS.

ROBLEM I.—To bisect a given straight line AB; that is, to divide it into two equal parts.

Fig. 93.

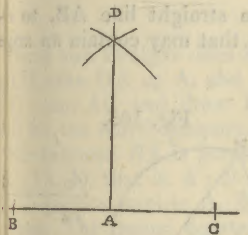


From the points A and B as centres, with any radius greater than the half of AB, describe arches, cutting each other in D and D on each side of the line AB. Draw a straight line through the points D, D, cutting AB in C; the line AB is bisected in C.

For the points D, D, being equally distant from the extremities of the line AB, are each in a straight line perpendicular to the middle of AB (16, 1), therefore the line DCD is that perpendicular, and consequently C is the middle of AB.

OBLEM II.—To draw a perpendicular to a given straight line BC, from a given point A in that line.

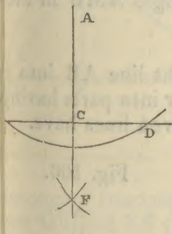
Fig. 94.



Take the points B and C at equal distances from A; and on B and C as centres, with any radius greater than BA, describe arches, cutting each other in D; draw a straight line from A through D, which will be the perpendicular required. For the point D, being at equal distances from the extremities of the line BC, must be in a perpendicular to the middle of BC (16, 1), therefore AD is the perpendicular required.

OBLEM III.—To draw a perpendicular to a given line BD, from a given point A without that line.

Fig. 95.

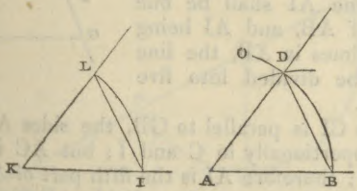


On A as a centre, with a radius sufficiently great, describe an arch, cutting the given line in two points B, D; and on B and D as centres, with a radius greater than the half of BD, describe two arches, cutting each other in F; draw a straight line through the points A and F, meeting BD in C; the line AC is the perpendicular required.

For the two points A and F are each at equal distances from B and D; therefore a line passing through A and F is perpendicular to the middle of BD (16, 1).

OBLEM IV.—At a given point A, in a given line AB, to make an angle equal to a given angle K.

Fig. 96.

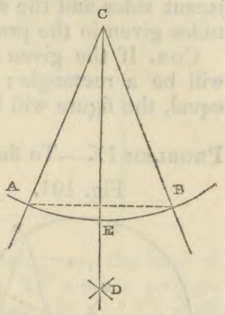


On K as a centre, with any radius, describe an arch to meet the lines containing the angle K in L and I; and on A as a centre, with the same radius, describe an indefinite arch BO; on B as a centre, with a radius equal to the chord LI, describe an arch, cutting the arch BO in D; draw AD, and the angle DAB shall be equal to K.

For the arches BD, LI having equal radii and equal chords, the arches themselves are equal (4, 2), therefore the angles A and K are also equal (13, 2).

Problem V.—To bisect a given arch AB, or a given angle C.

Fig. 97.



First, to bisect the arch AB, on A and B as centres, with one and the same radius, describe arches to intersect in D; join CD, cutting the arch in E, and the arch AE shall be equal to EB.

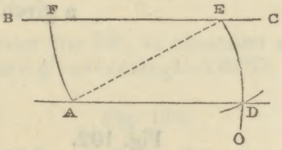
For, since the points C and D are at equal distances from A, and also from B, the line which joins them is perpendicular to the middle of the chord AB (16, 1), therefore the arch AB is bisected at E (6, 2).

Secondly, to bisect the angle C; on C as a centre, with any distance, describe an arch, meeting the lines containing the angle in A and B; then find the point D as before, and the line CD will manifestly bisect the angle C as required.

Scholium. By the same construction we may bisect each of the arches AE, EB; and again we may bisect each of the halves of these arches, and so on; thus, by successive subdivisions, an arch may be divided into four, eight, sixteen parts, &c.

Problem VI.—Through a given point A, to draw a straight line parallel to a given straight line BC.

Fig. 98.

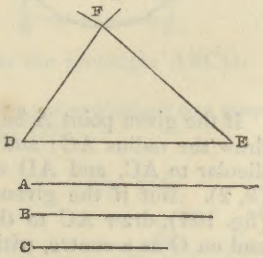


On A as a centre, with a radius sufficiently large, describe the indefinite arch EO; on E for a centre, with the same radius, describe the arch AF; in EO take ED equal to AF, draw a line from A through D, and AD will be parallel to BC.

For if AE be joined, the angle EAD is equal to AEB 13, 2), and they are alternate angles, therefore AD is parallel to BC (22, 1).

Problem VII.—To construct a triangle, the sides of which may be equal to three given lines A, B, C.

Fig. 99.



Take a straight line DE, equal to one of the given lines A; on D as a centre, with a radius equal to another of the lines B, describe an arch; on E as a centre, with a radius equal to the remaining line C, describe another arch, cutting the former in F; join DF and EF, and DEF will be the triangle required, as is sufficiently evident.

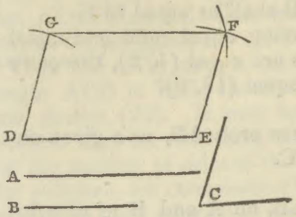
Scholium. It is necessary that the sum of any two of the lines be greater than the third line (7, 1).

Problem VIII.—To construct a parallelogram, the adjacent sides of which may be equal to two given lines A, B, and the angle they contain equal to a given angle C.

Lines and Figures upon a Plane.

Draw the straight line $DE = A$; make the angle $GDE = C$, and take $DG = B$; describe two arches, one on G as a centre, with a radius $GF = DE$, and the other on E, with a radius $EF = DG$; then DEFG shall be the parallelogram required.

Fig. 100.

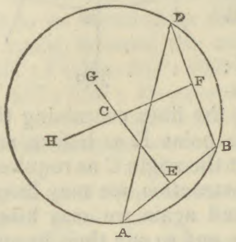


For by construction the opposite sides are equal; therefore the figure is a parallelogram (27, 1), and it is so constructed, that the adjacent sides and the angle they contain have the magnitudes given in the problem.

Cor. If the given angle be a right angle, the figure will be a rectangle; and if the adjacent sides be also equal, the figure will be a square.

Problem IX.—To find the centre of a given circle, or of a circle of which an arch is given.

Fig. 101.



Take any three points A, B, D, in the circumference of the circle, or in the given arch, and having drawn the straight lines AB, BD, bisect them by the perpendiculars EG, FH; the point C where the perpendiculars intersect each other is the centre of the circle, as is evident from Theorem VI. Sect. II.

Scholium. By the very same construction, a circle may be found that shall pass through three given points A, B, C; or that shall be described about a given triangle ADC.

Problem X.—To draw a tangent to a given circle through a given point A.

Fig. 102.

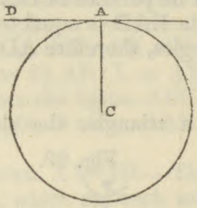


Fig. 103.

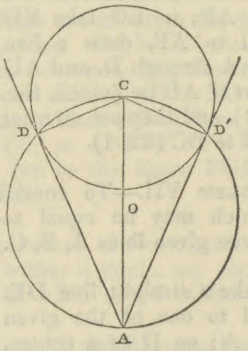


If the given point A be in the circumference (fig. 102), draw the radius AC; and through A, draw AD perpendicular to AC, and AD will be a tangent to the circle (9, 2). But if the given point A be without the circle (fig. 103), draw AC to the centre, and bisect AC in O, and on O as a centre, with OA or OC as a radius, describe a circle which will cut the given circle in two points D and D′; join AD and AD′, and each of the lines AD, AD′ will be a tangent to the circle.

For, draw the radii CD, CD′, then each of the angles ADC, AD′C is a right angle (17, 2); therefore AD and AD′ are both tangents to the circle (9, 2).

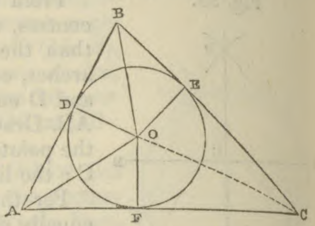
Cor. The two tangents AD, AD′ are equal to one another (17, 1).

Lines and Figures upon a Plane.

Problem XI.—To inscribe a circle in a given triangle ABC.

Bisect A and B any two angles of the triangle by the straight lines AO, BO, which meet each other in O; from O draw OD, OE, OF, perpendiculars to its sides; these lines shall be equal to one another.

Fig. 104.

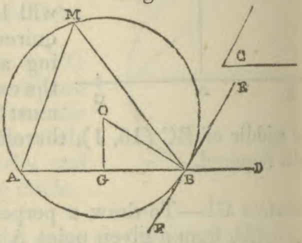


For in the triangles ODB, OEB, the angle $ODB = OEB$, and the angle $OBD = OBE$; therefore, the remaining angles BOD, BOE, are equal; and as the side OB is common to both triangles, they are equal to one another (6, 1), therefore the side $OD = OE$; in the same manner it may be demonstrated, that $OD = OF$; therefore the lines OD, OE, OF, are equal to one another; and consequently a circle described on O as a centre, with OD as a radius, will pass through E and F; and as the sides of the triangle are tangents to the circle (9, 2), it will be inscribed in the triangle.

Problem XII.—Upon a given straight line AB, to describe a segment of a circle that may contain an angle equal to a given angle C.

Produce AB towards D, and at the point B make the angle DBE equal to the given angle C; draw BO perpendicular to BE, and GO perpendicular to the middle of AB, meeting BO in O; on O as a centre, with OB as a radius, describe a circle, which will pass through A, and AMB shall be the segment required.

Fig. 105.

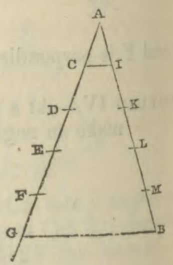


For since FE is perpendicular to BO, FE is a tangent to the circle; therefore the angle EBD (which is equal to C by construction) is equal to any angle AMB in the alternate segment (18, 2).

Problem XIII.—To divide a straight line AB into any proposed number of equal parts; or into parts having to each other the same ratios that given lines have.

First, let it be proposed to divide the line AB (fig. 106) into five equal parts. Through the extremity A draw an indefinite line AG, take AC of any magnitude, and take CD, DE, EF, and FG, each equal to AC, that is, take AG equal to five times AC; join GB, and draw CI parallel to GB, the line AI shall be one fifth part of AB, and AI being taken five times in AB, the line AB shall be divided into five equal parts.

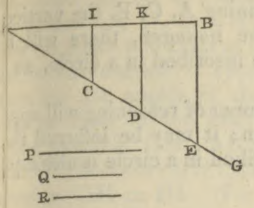
Fig. 106.



For since CI is parallel to GB, the sides AG and AB are cut proportionally in C and I; but AC is the fifth part of AG; therefore AI is the fifth part of AB.

Next, let it be proposed to divide AB (fig. 107) into parts, having to each other the ratios that the lines P, Q,

Fig. 107.

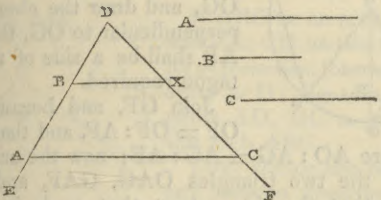


R have. Through A draw AG, and in AG take $AC = P$, $CD = Q$, $DE = R$; join EB, and draw CI and DK parallel to EB; the line AB shall be divided as required.

For, because of the parallels CI, DK, EB; the parts AI, IK, KB have to each other the same ratios that the parts AC, CD, DE have (17, 4), which parts are by construction equal to the given lines P, Q, R.

PROBLEM XIV.—To find a fourth proportional to three given lines A, B, C.

Fig. 108.



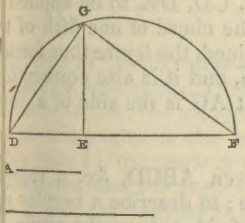
Draw two straight lines DE, DF, containing any angle; in DE take $DA = A$, and $DB = B$, and on DF take $DC = C$; join AC and draw BX parallel to AC; then DX shall be the fourth proportional required.

For because BX is parallel to AC, $DA : DB = DC : DX$ (17, 4), that is, $A : B = C : DX$; therefore DX is a fourth proportional to A, B, and C.

COR. The same construction serves to find a third proportional to two lines A and B; for it is the same as a fourth proportional to the lines A, B, and B.

PROBLEM XV.—To find a mean proportional between two straight lines A, B.

Fig. 109.

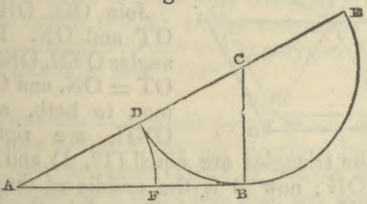


Upon any straight line DF take $DE = A$, and $EF = B$; and on DF as a diameter describe a semicircle DGF; draw EG perpendicular to DF, meeting the circle in G; the line EG shall be the mean proportional required.

For, if DG, FG be joined, the angle DGF is a right angle (17, 2), therefore, in the right-angled triangle DGF, GE is a mean proportional between DE and EF (23, 4).

PROBLEM XVI.—To divide a given straight line AB into two parts, so that the greater may be a mean proportional between the whole line and the other part.

Fig. 110.



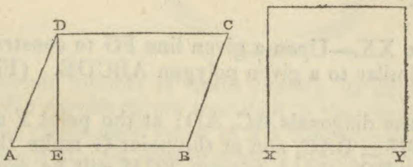
At B, one of the extremities of the line, draw BC perpendicular to AB, and equal to the half of AB; on C as a centre, with CB as a radius, describe a circle; join AC, meeting the circle in D; make $AF = AD$, and AB shall be divided at F in the manner required.

For since AB is perpendicular to the radius, it is a tangent to the circle (9, 2); and if AC be produced to meet the circle in E, $AB : AF = AE : AB$ (30, 4), and by division $AB - AF : AF = AE - AB : AB$; but $AB - AF = BF$; and since $DE = 2BC = AB$, therefore $AE - AB = AD = AF$, therefore $BF : AF = AF : AB$.

SCHOLIUM. When a line is divided in this manner, it is said to be divided in *extreme and mean ratio*.

PROBLEM XVII.—To make a square equivalent to a given parallelogram, or to a given triangle.

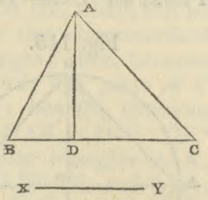
Fig. 111.



First, let ABCD be a given parallelogram, the base of which is AB, and altitude DE; find XY a mean proportional between AB and DE (by Problem 15), and XY shall be the side of the square required.

For since by construction $AB : XY = XY : DE$, therefore $XY^2 = AB \times DE$ (8, 4) = parallelogram ABCD (5, 4).

Fig. 112.

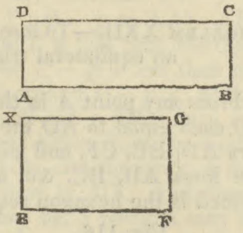


Next, let ABC be a given triangle (fig. 113), BC its base, and AD its altitude; find XY a mean proportional between half the base and the altitude, and XY shall be the side of the square required.

For since $\frac{1}{2}BC : XY = XY : AD$; therefore (8, 4) $XY^2 = \frac{1}{2}BC \times AD$ = triangle ABC (6, 4).

PROBLEM XVIII.—Upon a given line EF, to construct a rectangle EFGX equivalent to a given rectangle ABCD.

Fig. 113.

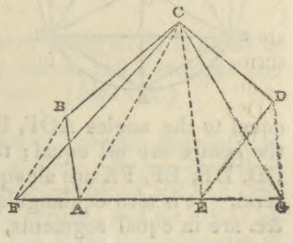


Find a fourth proportional to the three lines EF, AB, and AD (by Problem 14); draw EX perpendicular to EF, and equal to that fourth proportional, and complete the rectangle EFGX, which will have the magnitude required.

For since $EF : AB = AD : EX$, therefore (8, 4) $EF \times EX = AB \times AD$; that is, the rectangle EFGX is equal to the rectangle ABCD.

PROBLEM XIX.—To make a triangle equivalent to a given polygon ABCDE.

Fig. 114.



First, draw the diagonal CE, so as to cut off the triangle CDE; draw DG parallel to CE, to meet AE produced in G; join CG, and the given polygon ABCDE shall be equivalent to another polygon ABCG, which has one side fewer.

For since DG is parallel to CE, the triangle CGE is

Lines and Figures upon a Plane.

equivalent to the triangle CDE (2 Cor. 2, 4); to each add the polygon ABCE, and the polygon ABCDE shall be equivalent to the polygon ABCG.

In like manner, if the diagonal CA be drawn, also BF parallel to CA, meeting EA produced, and CF be joined, the triangle CFA is equivalent to the triangle CBA, and thus the polygon ABCDE is transformed to the triangle CFG.

In this way a triangle may be found equivalent to any other polygon; for by transforming the figure into another equivalent figure that has one side fewer, and repeating the operation, a figure will at last be found which has only three sides.

Scholium. As a square may be found equivalent to a triangle, by combining the problem with Prob. XVII. a square may be found equivalent to any rectilineal figure whatever.

Problem XX.—Upon a given line FG to construct a polygon similar to a given polygon ABCDE. (Fig. 88.)

Draw the diagonals AC, AD; at the point F make the angle $GFH = BAC$, and at the point G make the angle $FGH = ABC$; thus a triangle FGH will be constructed similar to ABC. Again, on FH construct in like manner a triangle FIH, similar to ADC and similarly situated; and on FI construct a triangle FKI similar to AED, and similarly situated; and these triangles FGH, FHI, FIK shall form a polygon FGHIK similar to ABCDE (26, 4).

Problem XXI.—To inscribe a square in a given circle.

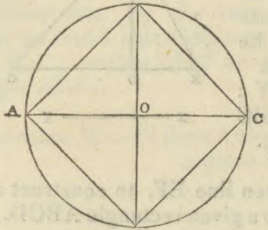


Fig. 115.

Draw two diameters AC, BD, so as to intersect each other at right angles; join the extremities of the diameters A, B, C, D, and the figure ABCD shall be a square inscribed in the circle.

For the angles AOB, BOC, &c. being all equal, the chords AB, BC, CD, DA are equal; and as each of the angles of the figure ABCD is in a semicircle, it is a right angle (17, 2), therefore the figure is a square.

Problem XXII.—To inscribe a regular hexagon, and also an equilateral triangle, in a given circle.

From any point A in the circumference, apply AB and BC each equal to AO the radius; draw the three diameters AD, BE, CF, and join their adjacent extremities by the lines AB, BC, &c. and the figure ABCDEF thus formed is the hexagon required.

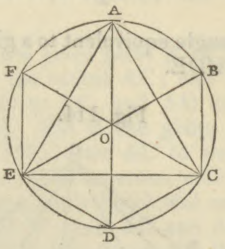

Fig. 116.

For the triangles AOB, BOC being by construction equilateral, each of the angles AOB, BOC is one third of two right angles (4, Cor. 24, 1); and since $AOB + BOC + COD =$ two right angles, therefore $COD =$ one third of two right angles; therefore the three angles AOB, BOC, COD are equal, and as these are equal to the angles AOF, FOE, EOD, the six angles at the centre are all equal; therefore the chords AB, BC, CD, DE, EF, FA are all equal; thus the figure is equilateral. It is also equiangular, for the angles FAB, ABC, &c. are in equal segments, each having for its base the chords of two sixths of the circumference; therefore the angles A, B, &c. are equal (15, 2).

If straight lines be drawn joining A, C, E, the vertices of the alternate angles of the hexagon, there will be formed an equilateral triangle inscribed in a circle, as is sufficiently evident.

Scholium. As the same manner of reasoning will apply alike to any equilateral polygon; it may be inferred that every equilateral polygon inscribed in a circle is also equiangular.

Problem XXIII.—To inscribe a regular pentagon and decagon in a given circle.

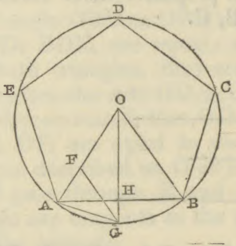

Fig. 117.

Draw any radius AO, and divide it into two parts AF, FO, such, that $AO : OF = OF : AF$ (16); from A place AG in the circumference equal to OF; join OG, and draw the chord AHB perpendicular to OG, the chord AB shall be a side of the pentagon required.

Join GF, and because $AO : OF = OF : AF$, and that $AG = OF$, therefore $AO : AG = AG : AF$; now the angle A is common to the two triangles OAG, GAF, and it has been shown that the sides about that angle in the two triangles are proportionals; therefore (22, 4), the triangles are similar, and the triangle AOG being isosceles, the triangle AGF is also isosceles, so that $AG = GF$; but $AG = FO$ (by construction), therefore, $GF = FO$, and the angle $FOG = FGO$, and $FOG + FGO = 2FOG$; but $AFG = FOG + FGO$ (23, 1), and $AFG = FAG$, therefore $FAG = 2FOG$; hence in the isosceles triangle AOG, each of the angles at the base is double the vertical angle AOG, therefore the sum of all the angles is equal to five times the vertical angle AOG; but the sum of all the angles is equal to two right angles (24, 1), therefore the angle AOG is one fifth of two right angles, and consequently $AOB = 2AOG =$ two fifths of two right angles, equal one fifth of four right angles, therefore the arch AB is one fifth of the whole circumference. If we now suppose straight lines BC, CD, DE, to be applied in the circle each equal to AB, the chord of one fifth of the circumference, and AE to be joined, the figure thus formed will be an equilateral pentagon, and it is also equiangular (Schol. 22). It is evident that AG is the side of a decagon inscribed in the circle.

Problem XXIV.—Having given ABCD, &c. a regular polygon inscribed in a circle; to describe a regular polygon of the same number of sides about the circle.

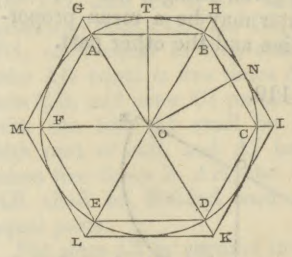

Fig. 118.

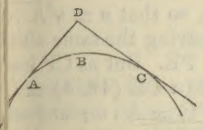
Draw GH a tangent to the circle at T the middle of the arch AB; do the same at the middle of each of the other arches BC, CD, &c.; these tangents shall form a regular polygon GHIK, &c. described about the circle.

Join OG, OH, &c. also OT and ON. In the triangles OTH, ONH, the side $OT = ON$, and OH is common to both, and OTH, ONH, are right angles, therefore the triangles are equal (17, 1) and the angle $TOH = NOH$; now B is the middle of the arch TN, therefore OH passes through B; and in the same manner it appears that I is in the line OC produced, &c. Now because OT bisects the arch AB, it is perpendicular to the chord AB (6, 2); therefore GH is parallel to AB (2, 2, and 18, 1), and HI to BC, therefore the angle GHO = ABO, and IHO = CBO, and hence GHI = ABC; and in like manner it appears that HIK = BCD, &c.; therefore the angles of the circumscribed polygon are equal to those of the inscribed polygon. And because of the parallels, GH : AB = OH : OB, and HI : BC = OH : OB, therefore GH : AB = HI : BC; but AB = BC; therefore GH = HI. For the same reason HI = IK, &c., therefore the polygon is regular, and similar to the inscribed polygon.

SECT. VI.—OF THE QUADRATURE OF THE CIRCLE.

Axiom.

Fig. 119.

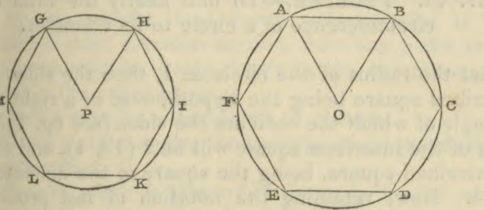


If ABC be an arch of a circle, and AD, CD be two tangents at its extremities, intersecting each other in D; the sum of the tangents AD, DC is greater than the arch ABC.

Cor. Hence the perimeter of any polygon described about a circle, is greater than the circumference of the circle.

Prop. I. Theorem.—Equilateral polygons, ABCDEF, GHIKLM, of the same number of sides inscribed in circles are similar, and are to one another as the squares of the radii of the circles.

Fig. 120.

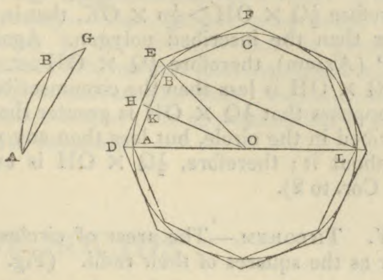


As each of the polygons is by hypothesis equilateral, it will also be equiangular (Schol. 22, 5). Let us suppose, for example, that the polygons are hexagons; then, as the sum of the angles is the same in both, viz. eight right angles (25, 1), the angle A will be one sixth part of eight right angles, and the angle G will be the same; therefore A = G; in like manner B = H, C = I, &c., and as the figures are equilateral, AB : GH = BC : HI = CD : IK, &c. therefore (2, Def. 4) the figures are similar. Draw AO, BO, GP, HP to the centres of the circles; then, because the angle AOB is the same part of four right angles that the arch AB is of the whole circumference, and the angle GPH the same part of four right angles that GH is of the whole circumference (13, 2), the angles AOB, GPH are each the same part of four right angles; therefore they are equal; the isosceles triangles AOB, GPH are therefore similar (22, 4), and consequently AB : GH = AO : GP; therefore (9 and 27, 4) polygon ABCDEF : polygon GHIKLM = $AO^2 : GP^2$.

Prop. II. Theorem.—A circle being given, two similar polygons may be found, the one inscribed in the circle, and the other described about it, which shall differ from each other by a space less than any given space.

Let AG be the side of a square equal to the given space; and let ABG be such an arch of the given circle, that AG is its chord. Bisect the fourth part of the circumference (5, 5), then bisect one of its halves, and proceed in this manner till, by repeated bisections, there will at length be found an arch AB less than AG. As the arch thus found will be contained in the circumference a certain number of times exactly, its chord AB is the side of a regular figure inscribed in the circle; apply lines in the circle, each equal to AB, thus forming the regular figure ABC, &c., and describe a regular figure DEF, &c. of the same number of sides about the circle. Then the excess of the circumscribed figure above the inscribed figure shall be less than the square upon AG. For draw lines from D and E to O the centre, these lines will pass through A and B (24, 5); also, a line drawn from O, to H the point of contact of the line DE, will bisect AB, and be perpendicular to it; and AB will be parallel to DE. Draw the diameter AL, and join BL, which will be parallel to HO (18, 4). Put P for the circumscribed polygon, and p for the inscribed polygon; then, because the triangles ODH, OAK are evidently like parts of P and p, $P : p = ODH : OAK$ (1, 3); but the triangles ODH, OAK being similar, $ODH : OAK = OH^2 : OK^2$ (25, 4); and on account of the similar triangles OAK, LAB, OA^2, or $OH^2 : OK^2 = LA^2 : LB^2$ (20, and 9, 4); therefore $P : p = LA^2 : LB^2$, and by division and inversion, $P : P - p = LA^2 : LA^2 - LB^2$, or AB^2; but LA^2, that is, the square described about the circle, is greater than the equilateral polygon of eight sides described about the circle, because it contains that polygon, and for the same reason the polygon of eight sides is greater than the polygon of sixteen sides, and so on; therefore $LA^2 > P$, and as it has been proved that $P : P - p = LA^2 : AB^2$, of which proportion the first term P is less than the third LA^2; therefore (2, 3) the second $P - p$ is less than the fourth AB^2; but $AB^2 < AG^2$, therefore $P - p < AG^2$.

Fig. 121.



Cor. 1. Because the polygons P and p differ from one another more than either of them differs from the circle, the difference between each of them, and the circle, is less than the given space, viz. the square of AG. And therefore, however small any space may be, a polygon may be inscribed in the circle, and another described about it, each of which shall differ from the circle by less than the given space.

Cor. 2. A space which is greater than any polygon that can be inscribed in a circle, but which is less than any polygon that can be described about it, is equal to the circle itself.

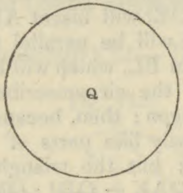
Prop. III. Theorem.—The area of any circle is equal to a rectangle contained by the radius, and a straight line equal to half the circumference. (Fig. 121.)

Let ABC, &c. be any equilateral polygon inscribed in the circle, and DEF, &c. a similar polygon described about it; draw lines from the extremities of AB and DE, a side of each polygon, to O the centre; and let OKH be perpendicular to these sides. Put P for the perimeter of the polygon DEF, &c. and p for the perimeter of the polygon ABC, &c. and n for the number of the sides of each. Then, because $n \times \frac{1}{2}\text{DE} = \frac{1}{2}\text{P}$, $n \times \frac{1}{2}\text{DE} \times \text{OH} = \frac{1}{2}\text{P} \times \text{OH}$, but $n \times \frac{1}{2}\text{DE} \times \text{OH} = n \times$ triangle DOE $=$ polygon DEF, &c.; therefore, $\frac{1}{2}\text{P} \times \text{OH} =$ polygon DEF, &c.; and in like manner it appears that $\frac{1}{2}p \times \text{OK} =$ polygon ABC, &c. Now let Q denote the circumference of the circle, then, because $\frac{1}{2}\text{Q} > \frac{1}{2}p$, and $\text{OH} > \text{OK}$, therefore $\frac{1}{2}\text{Q} \times \text{OH} > \frac{1}{2}p \times \text{OK}$, that is, $\frac{1}{2}\text{Q} \times \text{OH}$ is greater than the inscribed polygon. Again, because $\frac{1}{2}\text{Q} < \frac{1}{2}\text{P}$ (Axiom), therefore $\frac{1}{2}\text{Q} \times \text{OH} \angle \frac{1}{2}\text{P} \times \text{OH}$, that is, $\frac{1}{2}\text{Q} \times \text{OH}$ is less than the circumscribed polygon. Thus it appears that $\frac{1}{2}\text{Q} \times \text{OH}$ is greater than any polygon inscribed in the circle, but less than any polygon described about it; therefore, $\frac{1}{2}\text{Q} \times \text{OH}$ is equal to the circle (2 Cor. to 2).

Prop. IV. Theorem.—The areas of circles are to one another as the squares of their radii. (Fig. 120, 122).

Let ABCDEF and GHIKLM be equilateral polygons of the same number of sides inscribed in the circles, and OA, PG their radii; and let Q be such a space, that $\text{AO}^2 : \text{GP}^2 =$ circle ABE : Q; then, because $\text{AO}^2 : \text{GP}^2 =$ polygon ABCDEF : polygon GHIKLM, and $\text{AO}^2 : \text{GP}^2 =$ circle ABE : Q, therefore polygon ABCDEF : polygon GHIKLM $=$ circle ABE : Q; but circle ABE $>$ polygon ABCDEF, therefore Q $>$ polygon GHIKLM: that is, Q is greater than any polygon inscribed in the circle GHL. In the same manner it is demonstrated that Q is less than any polygon described about the circle GHL; therefore Q is equal to the circle GHL (2). And because $\text{AO}^2 : \text{GP}^2 =$ circle ABE : Q, therefore $\text{AO}^2 : \text{GP}^2 =$ circle ABE : circle GHL.

Fig. 122.



Cor. I. The circumferences of circles are to one another as their radii. Put M for the circumference of the circle ABE and N for the circumference of GKL; then, circle ABE : circle GHL $= \text{AO}^2 : \text{GP}^2$; but $\frac{1}{2}\text{M} \times \text{AO} =$ circle ABE, also $\frac{1}{2}\text{N} \times \text{GP} =$ circle GHL (3), therefore $\frac{1}{2}\text{M} \times \text{AO} : \frac{1}{2}\text{N} \times \text{GP} = \text{AO}^2 : \text{GP}^2$, and by alternation $\frac{1}{2}\text{M} \times \text{AO} : \text{AO}^2 = \frac{1}{2}\text{N} \times \text{GP} : \text{GP}^2$, therefore (3, 4), $\frac{1}{2}\text{M} : \text{AO} = \frac{1}{2}\text{N} : \text{GP}$; and again, by alternation, $\frac{1}{2}\text{M} : \frac{1}{2}\text{N} = \text{AO} : \text{GP}$, therefore $\text{M} : \text{N} = \text{AO} : \text{GP}$.

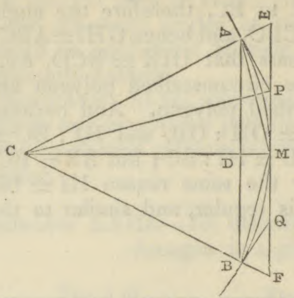
Cor. 2. A circle described with the hypothenuse of a right-angled triangle as a radius, is equal to two circles described with the other two sides as radii. Let the sides of the triangle be a, b and the hypothenuse h, and let the circles described with these lines as radii be A, B, and H.

$$\begin{aligned} &\text{Because } \text{A} : \text{H} = a^2 : h^2 \\ &\text{and } \text{B} : \text{H} = b^2 : h^2, \\ &\text{therefore } \text{A} + \text{B} : \text{H} = a^2 + b^2 : h^2 \ (10, 3); \\ &\text{but } a^2 + b^2 = h^2 \ (13, 4), \text{ therefore } \text{A} + \text{B} = \text{H}. \end{aligned}$$

Prop. V. Problem.—Having given the area of a regular polygon inscribed in a circle, and also the area of a similar polygon described about it; to find the areas of regular inscribed and circumscribed polygons, each of double the number of sides.

Let AB be the side of the given inscribed polygon, and EF parallel to AB that of the similar circumscribed polygon, and C the centre of the circle; if the chord AM, and the tangents AP, BQ be drawn, the chord AM shall be the side of the inscribed polygon of double the number of sides; and PQ or 2PM that of the similar circumscribed polygon. Put A for the area of the polygon, of which AB is a side, and B for the area of the circumscribed polygon; also a for the area of the polygon of which AM is a side, and b for the area of the similar circumscribed polygon; then A and B are by hypothesis known, and it is required to find a and b.

Fig. 123.



I. The triangles ACD, ACM, which have a common vertex A, are to one another as their bases CD, CM; besides, these triangles are to one another as the polygons, of which they form like parts, therefore $\text{A} : a = \text{CD} : \text{CM}$. The triangles CAM, CME, which have a common vertex M, are to each other as their bases CA, CE; they are also to one another as the polygons a and B, of which they are like parts; therefore, $a : \text{B} = \text{CA} : \text{CE}$; but because of the parallels DA, ME, $\text{CD} : \text{CM} = \text{CA} : \text{CE}$; therefore, $\text{A} : a = a : \text{B}$; therefore the polygon a, which is one of the two required, is a mean proportional between the two known polygons A and B, so that $a = \sqrt{\text{A} \times \text{B}}$.

II. The triangles CPM, CPE, having the same altitude CM, are to one another as PM to PE. But as CP bisects the angle MCE, $\text{PM} : \text{PE} = \text{CM} : \text{CE}$ (19, 4) $= \text{CD} : \text{CA} = \text{A} : a$; therefore $\text{CPM} : \text{CPE} = \text{A} : a$; and consequently $\text{CPM} + \text{CPE}$, or $\text{CME} : \text{CPM} = \text{A} + a : \text{A}$, and $\text{CME} : 2\text{CPM} = \text{A} + a : 2\text{A}$; but CME and 2CPM, or CMPA, are to one another as the polygons B and b, of which they are like parts; therefore $\text{A} + a : 2\text{A} = \text{B} : b$. Now the polygon a has been already found, therefore by this last proportion the polygon b is determined; that is, $b = \dfrac{2\text{A} \times \text{B}}{\text{A} + a}$.

Prop. VI. Problem.—To find nearly the ratio of the circumference of a circle to its diameter.

Let the radius of the circle $= 1$, then the sides of the inscribed square being the hypothenuse of a right-angled triangle of which the radii are the sides (see fig. 115), the area of the inscribed square will be 2 (13, 4), and the circumscribed square, being the square of the diameter, will be 4. Now, retaining the notation of last problem, if we make $\text{A} = 2$, and $\text{B} = 4$, the formulæ $a = \sqrt{\text{A} \times \text{B}}$, $b = \dfrac{2\text{A} \times \text{B}}{\text{A} + a}$ give us $a = 2{\cdot}8284271$, &c. the area of the inscribed octagon, and $b = 3{\cdot}31337085$, &c. the area of the circumscribed octagon. By substituting these numbers in the formula, instead of A and B, we shall obtain the areas of the inscribed and circumscribing polygons of 16 sides; and thence we may find those of 32 sides, and so on, as in the following table:

No. of Sides.	Ins. Polygons.	Circ. Polygons.
4	2·0000000	4·0000000
8	2·8284271	3·3137085
16	3·0614674	3·1825979
32	3·1214451	3·1517249
64	3·1365485	3·1441184
128	3·1403311	3·1422236
256	3·1412772	3·1417504
512	3·1415138	3·1416321
1024	3·1415729	3·1416025
2048	3·1415877	3·1415951
4096	3·1415914	3·1415133
8192	3·1415923	3·1415928
16384	3·1415925	3·1415927
32768	3·1415926	3·1415926

Hence it appears that the area of a regular polygon of 32768 sides inscribed in the circle, and of a similar polygons described about it, differ so little from each other that the numbers which express them are the same as far as the eighth decimal place. And as the circle is greater than the one polygon, and less than the other, its area will be nearly 3·1415926. But the area is the product of the radius and the half of the circumference; therefore the radius being unity, half the circumference is 3·1415926 nearly; and the radius is to half the circumference, or the diameter is to the circumference, nearly as 1 to 3·1415926.

Scholium. In this way the ratio of the diameter to the circumference may be found to any degree of accuracy; but neither by this, nor any other method yet known, can the ratio be exactly determined.

Archimedes, by means of inscribed and circumscribed polygons of 96 sides, found that the diameter is to the circumference as 7 to 22 nearly, which ratio is nearer to the truth than can be expressed by any smaller numbers; and Metius found it to be more nearly as 113 to 355. Both of these expressions are convenient on account of the smallness of the numbers, but later mathematicians have carried the approximation to a much greater degree of accuracy. Thus, it has been found that the diameter being 1, the circumference is greater than 3·1415926535897932, but less than the same number having its last figure increased by unity; and some have even had the patience to carry the approximation as far as the 150th place of decimals.

PART II.—GEOMETRY OF SOLIDS.

SECT. I.—OF PLANES AND SOLID ANGLES.

Definitions.

I. A straight line is *perpendicular*, or at right angles, to a plane, when it is perpendicular to every straight line which it meets in that plane. The plane is also perpendicular to the line.

II. A line is *parallel* to a plane when they cannot meet each other, although both be produced. The plane is also parallel to the line.

III. Parallel planes are such as cannot meet each other, though produced.

IV. It will be demonstrated (Theor. 3) that the common section of two planes is a straight line; this being premised, the *inclination* of two planes is the angle contained by two straight lines drawn perpendicular to the line which is their common section, from any point in it, the one perpendicular being drawn in the one plane, and the other in the other plane.

This angle may be either acute or obtuse.

V. If it be a right angle, the two planes are perpendicular to each other.

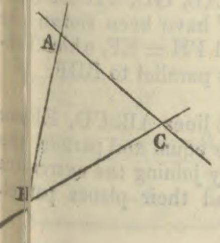
VI. A *solid angle* is that which is made by the meeting of more than two plane angles, which are not in the same plane, in one point. Thus the solid angle V is formed by the plane angles AVB, BVC, CVD, DVA. (Fig. 133.)

Theorem I.—One part of a straight line cannot be in a plane and another part above it.

For from the definition of a plane (Sect. 1, Part 1), it is manifest, that if a straight line coincide with a plane in two points, it must be wholly in the plane.

Theorem II.—Two straight lines which cut each other in a plane determine its position; that is, the plane can coincide with these lines only in one position.

Fig. 124.

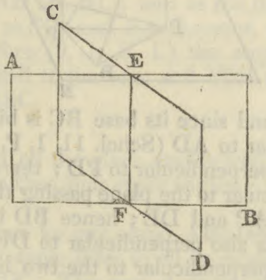


Let the straight lines AB, AC cut each other in A; conceive a plane to pass through AB, and to be turned about that line, till it pass through the point C; and this it can manifestly do only in one position; then, as the points A and C are in the plane, the whole line AC must be in the plane; therefore there is only one position in which the plane can coincide with the same two lines AB, AC.

Cor. Therefore a triangle ABC, or three points A, B, C, not in a straight line, determine the position of a plane.

Theorem III.—If two planes AB, CD intersect each other; their intersection is a straight line.

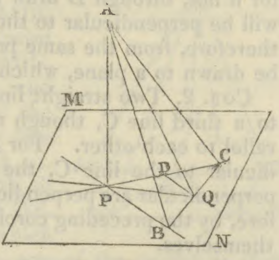
Fig. 125.



Let E and F be two points in the line of common section, and let a straight line EF be drawn between them; then the line EF must be in the plane AB (Def. 1), and the same line must also be in the plane CD; therefore it must be the common section of them both.

Theorem IV.—If a straight line AP be perpendicular to two straight lines PB, PC at P, the point of their intersection; it will also be perpendicular to the plane MN, in which these lines are.

Fig. 126.



Draw any other line PQ in the plane MN, and from Q, any point in that line, draw QD parallel to PB; make DC = DP; join CQ, meeting PB in B; and join AB, AQ, AC. Because DQ is parallel to PB, and PD = DC; therefore BQ = QC, and BC is bisected in Q. Hence in the triangle BAC,

$$AB^2 + AC^2 = 2AQ^2 + 2BQ^2 \ (16, 4),$$

and in the like manner, in the triangle PBC,

$$PB^2 + PC^2 = 2PQ^2 + 2CQ^2;$$

therefore, taking equal quantities from equal quantities, that is, subtracting the two last quantities, which are put equal to each other, from the two first, and observing, that as APB, APC are by hypothesis right-angled triangles, $AB^2 - BP^2 = AP^2$, and $AC^2 - CP^2 = AP^2$, we have

$$AP^2 + AP^2 = 2AQ^2 - 2PQ^2,$$

and therefore $AP^2 = AQ^2 - PQ^2$, or $AP^2 + PQ^2 = AQ^2$; therefore the triangle APQ is right-angled at P (Schol. 15, 4, Part 1), and consequently AP is perpendicular to the plane MN (Def. 1).

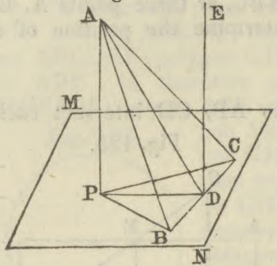
Cor. 1. The perpendicular AP is shorter than any oblique line AQ, therefore it measures the distance of the point A from the plane.

Cor. 2. From the same point P in a plane no more than one perpendicular can be drawn. For if it be possible that there can be two perpendiculars, conceive a plane to pass through them, and to intersect the plane MN in the straight line PQ; then these perpendiculars will be in the same plane, and both perpendicular to the same line PQ, at the same point P in that line, which is impossible.

It is also impossible that from a point without a plane two perpendiculars can be drawn to the plane; for if the straight lines AP, AQ could be two such perpendiculars, then the triangle APQ would have two right angles, which is impossible.

Theorem V.—If a straight line AP be perpendicular to a plane MN, every straight line DE parallel to AP is perpendicular to the same plane.

Fig. 127.



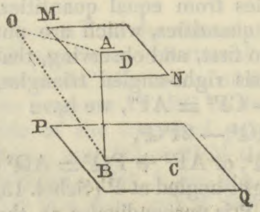
Let a plane pass through the parallel lines AP, DE, and intersect the plane MN in the line PD; through D draw BC at right angles to PD; take $DC = DB$, and join PB, PC, AB, AC, AD. Because $DB = DC$, therefore $PB = PC$ (Cor. 5, 1, Part I.); and because AP is perpendicular to the plane MN, so that APB, APC are right angles, $AB = AC$, therefore ABC is an isosceles triangle; and since its base BC is bisected at D, BC is perpendicular to AD (Schol. 11, 1, P. I.); but by construction BC is perpendicular to PD; therefore (4) BC or BD is perpendicular to the plane passing through the lines AD and PD, or AP and DE; hence BD is perpendicular to DE, but PD is also perpendicular to DE (19, 1, P. I.), therefore DE is perpendicular to the two lines DP, DB; and therefore it is perpendicular to the plane MN passing through them.

Cor. 1. Conversely, if the straight lines AP, DE be perpendicular to the same plane MN, they are parallel; for if not, through D draw a parallel to AP; this parallel will be perpendicular to the plane MN (by the theorem), therefore, from the same point D two perpendiculars may be drawn to a plane, which is impossible (4).

Cor. 2. Two straight lines A and B which are parallel to a third line C, though not in the same plane, are parallel to each other. For suppose a plane to be perpendicular to the line C, the lines A and B parallel to this perpendicular are perpendicular to the same plane; therefore, by the preceding corollary, they are parallel between themselves.

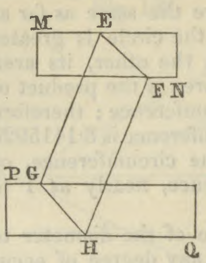
Theorem VI.—Two planes MN, PQ, perpendicular to the same straight line AB, are parallel to each other.

Fig. 128.



For, if they can meet each other, let O be a point common to both, and join OA, OB; then the line AB, which is perpendicular to the plane MN, must be perpendicular to AO, a line drawn in the plane MN from the point in which AB meets that plane. For the same reason AB is perpendicular to BO; therefore OA, OB are two perpendiculars drawn from the same point O, to the same straight line AB, which is impossible.

Fig. 129.



Theorem VII.—The intersections EF, GH of two parallel planes MN, PQ with a third plane FG, are parallel.

For if the lines EF, GH, situated in the same plane, are not parallel, they must meet if produced; therefore the planes MN, PQ, in which they are, must also meet, which is contrary to the hypothesis of their being parallel.

Theorem VIII.—Any straight line AB, perpendicular to MN one of two parallel planes MN, PQ, is also perpendicular to PQ the other plane. (Fig. 128.)

From B draw any straight line BC in the plane PQ, and let a plane pass through the lines AB, BC, and meet the plane MN in the line AD, then AD will be parallel to BC (7); and since AB is perpendicular to the plane MN, it must be perpendicular to the line AD, therefore it is also perpendicular to BC (19, 1, P. I.); hence (Def. 1) the line AB is perpendicular to the plane PQ.

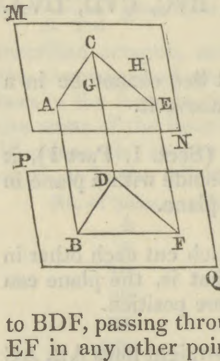
Theorem IX.—Parallel straight lines EG, FH, comprehended between two parallel planes MN, PQ, are equal. (Fig. 129.)

Let a plane pass through the lines EG, FH, and meet the parallel planes in EF and GH; then EF and GH are parallel (7) as well as EG and FH; therefore EGHF is a parallelogram, and $EG = HF$.

Cor. Hence two parallel planes are everywhere at the same distance from each other. For if EG and FH be perpendicular to the two planes, they are parallel (1 Cor. 5); therefore they are equal.

Theorem X.—If two straight lines CA, EA, meeting one another, be parallel to two other lines DB, FB, that meet one another, though not in the same plane with the first two; the first two and the other two shall contain equal angles, and the plane passing through the first two shall be parallel to the plane passing through the other two.

Fig. 130.



Take $AC = BD$, $AE = BF$, and join CE, DF, AB, CD, EF. Because AC is equal and parallel to BD, the figure ABDC is a parallelogram; therefore CD is equal and parallel to AB. For a similar reason EF is equal and parallel to AB; therefore also CE is equal and parallel to DF (Cor. 5, and 28, 1, P. I.); therefore the triangles CAE, DBF are equal (10, 1, P. I.), hence the angle $CAE = DBF$.

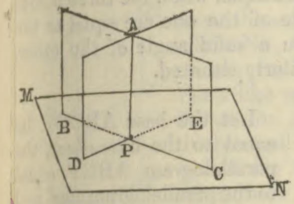
In the next place, the plane ACE is parallel to the plane BDF: for suppose that the plane parallel to BDF, passing through the point A, meets the lines CD, EF in any other points than C and E (for example in G and H), then (9) the three lines AB, GD, FH are equal; but the three lines AB, CD, EF have been shown to be equal; therefore $CD = GD$, and $FH = EF$, which is absurd, therefore the plane ACE is parallel to BDF.

Theorem XI.—If three straight lines AB, CD, EF, not situated in the same plane, are equal and parallel; the triangles ACE, BDF formed by joining the extremities of these lines are equal, and their planes parallel. (See fig. 130.)

For since AB is equal and parallel to CD, the figure ABDC is a parallelogram; therefore the side AC is equal and parallel to BD. In like manner it may be shown that the sides AE, BF are equal and parallel; also CE, DF; therefore the triangles CAE, BDF are equal. It may be demonstrated, as in last proposition, that their planes are parallel.

Theorem XII.—If a straight line AP be perpendicular to a plane MN; any plane APB, passing through AP, shall be perpendicular to the plane MN.

Fig. 131.



Let BC be the intersection of the planes AB, MN; if in the plane MN the line DE be drawn perpendicular to BP, the line AP, being perpendicular to the plane MN, shall be perpendicular to each of the straight lines BC, DE; therefore the angle APD is a right angle; now PA and PD are drawn in the planes AB, MN perpendicular to their common section, therefore (5 Def.) the planes AB, MN are perpendicular to each other.

Scholium. When three straight lines, such as AP, BP, DP, are perpendicular to each other, each is perpendicular to the plane of the two other lines.

Theorem XIII.—If the plane AB be perpendicular to the plane MN, and if in the plane AB a straight line PA be drawn perpendicular to BP, the common intersection of the planes; then shall PA be perpendicular to the plane MN. (Fig. 131.)

For, if in the plane MN, a line PD be drawn perpendicular to PB, the angle APD shall be a right angle, because the planes are perpendicular to each other; therefore the line AP is perpendicular to the two lines PB, PD, and therefore it is perpendicular to their plane MN.

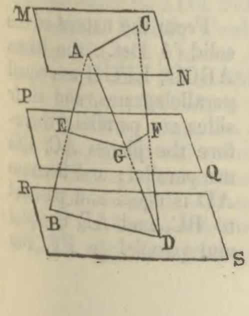
Cor. If the plane AB be perpendicular to the plane MN, and from any point P, in their common intersection, a perpendicular be drawn to the plane MN; this perpendicular shall be in the plane AB; for if it is not, a perpendicular AP may be drawn in the plane AB to the common intersection BP, which will be at the same time perpendicular to the plane MN; therefore, at the same point P, there may be two perpendiculars to a plane NM, which is impossible (4).

Theorem XIV.—If two planes AB, AD be perpendicular to a third; their common intersection AP is perpendicular to the third plane. (Fig. 131.)

For, if through the point P a perpendicular be drawn to the plane MN, this perpendicular shall be in the plane AB, and also in the plane AD (Cor. 12); therefore it is at their common intersection AP.

Theorem XV.—If two straight lines be cut by parallel planes; they shall be cut in the same ratio.

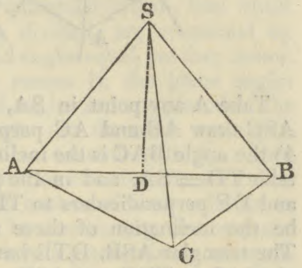
Fig. 132.



Let the line AB meet the planes MN, PQ, RS, in A, E, B; and let CD meet them in C, F, D, then shall $AE : EB = CF : FD$. For draw AD meeting the plane PQ in G, and join AC, EG, GF, BD; the lines EG, BD being the common sections of the plane of the triangle ABD and the parallel planes PQ, RS, they are parallel (7); and in like manner it appears, that AC, GF are parallel; therefore $AE : EB \; (= AG : GD) = CF : FD$.

Theorem XVI.—If a solid angle be contained by three plane angles; the sum of any two of these is greater than the third.

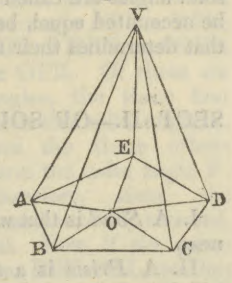
Fig. 133.



It is evidently only necessary to demonstrate the theorem, when the plane angle which is compared with the sum of the other two is greater than either of them; for, if it were equal to or less than one of them, the theorem would be manifest; therefore let S be a solid angle formed by three plane angles ASB, ASC, BSC, of which ASB is the greatest. In the plane ASB make the angle $BSD = BSC$; draw any straight line ADB, and having taken $SC = SD$, join AC, BC; the triangles BSC, BSD, having two sides, and the included angle of the one equal to two sides, and the included angle of the other, each to each, are equal (5, 1, P. I.), therefore $BD = BC$; now $AB \angle AC + BC$, therefore, taking BD from the first of these unequal quantities, and BC from the second, we get $AD \angle AC$; and as the triangles ASD, ASC have $SD = SC$, and SA common to both, and $AD \angle AC$, therefore (9, 1, P. I.) the angle $ASD \angle ASC$; and, adding DSB to the one, and CSB to the other, $ASB \angle ASC + BSC$.

Theorem XVII.—The sum of all the plane angles which form any solid angle is less than four right angles.

Fig. 134.



Let the solid angle V be cut by any plane ABCDE; from a point O taken in this plane, draw to all its angles the lines OA, OB, OC, OD, OE. The sum of all the angles of the triangles AVB, BVC, &c. formed about the vertex V is equivalent to the sum of the angles of a like number of triangles AOB, BOC, &c. formed about the point O. Now at B the angle ABC, which is the sum of OBA and OBC, is less than the sum of the angles VBA, VBC (16); in like manner at C, $OCB + OCD \angle VCB + VCD$, and so on with all the angles of the polygon ABCDE. Hence, in the triangles of which the common vertex is O, the sum of the angles at their bases is less than the sum of the angles at the bases of the triangles which have their vertex at V; therefore the sum of the angles about the point O is greater than the sum of the angles about the point V. But the sum of the angles about O is equal to four right angles, therefore the sum of the plane angles which form the solid angle about the vertex V is less than four right angles.

Scholium. This demonstration supposes that the solid angle is convex, or that it lies all on one side of the plane of any one of its faces. If it were otherwise, the sum of the solid angles would be unlimited.

Theorem XVIII.—If each of two solid angles be contained by three plane angles equal to one another, each to each; the planes in which the equal angles are, have the same inclination to one another.

Let the angle ASB = DTE, the angle ASC = DTF, and the angle BSC = ETF; the two planes ASB, ASC shall have to each other the same inclination as the two planes DTE, DTF.

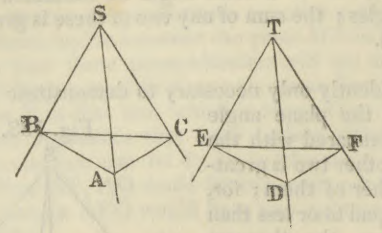


Fig. 135.

Take A any point in SA, and in the two planes ASB, ASC draw AB and AC perpendiculars to AS, then (Def. 4) the angle BAC is the inclination of these planes; again, take TD = SA, and in the planes TDE, TDF draw DE and DF perpendiculars to TD, and the angle EDF shall be the inclination of these other planes; join BC, EF. The triangles ASB, DTE have the side AS=DT, the angle SAB = TDE and ASB = DTE, therefore the triangles are equal, and thus AB = DE, and SB = TE. In like manner it appears that the triangles ASC, DTF are equal, and therefore that AC = DF, and SC = TF. Now the triangles BSC, ETF, having BS = TE, SC = TF, and the angle BSC = ETF, are also equal, and therefore BC = EF; but it has been shown that AB = DE, and that AC = DF; therefore the triangles BAC, EDF are equal, and consequently the angle BAC = EDF; that is, the inclination of the planes ASB and ASC is equal to the inclination of the planes DTE and DTF. In the same manner it may be proved that the other planes have the same inclination to one another.

Scholium. If the three plane angles which contain the solid angles are equal, each to each; and if the angles are also *disposed in the same order* in the two solid angles, then these angles when applied to one another will coincide and be equal. But if the plane angles be *disposed in a contrary order*, the solid angles will not coincide, although the theorem is equally true in both cases. In this last case, the solid angles are called *Symmetrical angles*, and they must be accounted equal, because they are equal in every thing that determines their magnitude.

SECT. II.—OF SOLIDS BOUNDED BY PLANES.

Definitions.

I. A *Solid* is that which has length, breadth, and thickness.

II. A *Prism* is a solid contained by plane figures, of which two that are opposite are equal, similar, and parallel; and the others are parallelograms.

To construct this solid, let ABCDE be any polygon, fig. 136; if in a plane parallel to ABC there be drawn straight lines FG, GH, HI, &c. equal and parallel to the sides AB, BC, CD, &c. so as to form a polygon FGHIK equal to ABCDE, and straight lines AF, BG, CH, &c. be drawn, joining the vertices of the homologous angles in the two planes; the planes or faces ABGF, BCHG, &c. thus formed will be parallelograms; and the solid ABCDEFGHIK contained by these parallelograms and the two polygons is the prism itself.

III. The equal and parallel polygons ABCDE, FGHIK are called the *Bases* of the prism; and the distance between the bases is its *Altitude*.

IV. When the base of a prism is a parallelogram, and consequently the figure has all its faces parallelograms; it is called a *parallelopiped*. A parallelopiped is *rectangular*, when all its faces are rectangles.

V. A *Cube* is a rectangular parallelopiped contained by six equal squares.

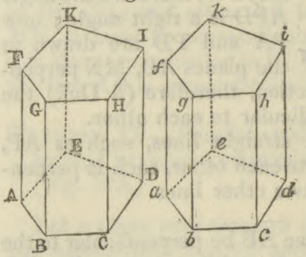
VI. A *Pyramid* is a solid contained by several planes, which meet in the same point V, and terminate in a polygonal plane ABCDE. Fig. 134.

VII. The polygon ABCDE is called the *Base* of the pyramid; the point V is its *Vertex;* and a perpendicular let fall from the vertex upon the base is called its *Altitude*.

VIII. Two solids are *similar* when they are contained by the same number of similar planes, similarly situated, and having like inclinations to one another.

Theorem I.—Two prisms are equal when the three planes which contain a solid angle of the one are equal to the three planes which contain a solid angle of the other, each to each, and are similarly situated.

Fig. 136.



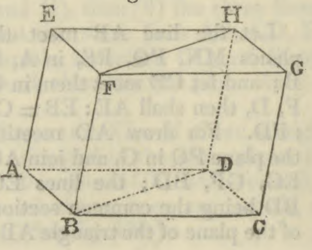
Let the base ABCDE be equal to the base *abcde*, the parallelogram ABGF equal to the parallelogram *abgf*, and the parallelogram BCHG equal to the parallelogram *bchg*; the prism ABCI shall be equal to the prism *abci*.

For let the base ABCDE be applied to its equal the base *abcde*, so that they may coincide with each other; then, because the three plane angles which form the solid angle B are equal to the three plane angles which form the angle *b*, each to each, viz. ABC = *abc*, ABG = *abg*, and GBC = *gbc*, and because these angles are similarly situated, the solid angles B and *b* are equal (15, 1), therefore the side BG shall fall upon the side *bg;* and because the parallelograms ABGF, *abgf* are equal, the side FG shall fall upon its equal *fg;* in like manner it may be shown that GH falls upon *gh*, therefore the upper base FGHIK coincides entirely with its equal *fghik*, and the two solids coincide with each other, or occupy the same space, therefore the prisms are equal.

Cor. Two right prisms which have equal bases and equal altitudes are equal to one another. If the equal angles of the lower bases follow each other in the same order, then the three planes which contain each solid angle of the one prism will be respectively equal to the three planes which contain a solid angle of the other prism, and will be similarly situated; and when the one solid angle is applied to the other, these planes will coincide, and the prisms will exactly coincide. If the equal angles of the lower base follow each other in a contrary order, then, by inverting one of the prisms, so that its upper may become its lower base, the angles of the two bases will follow each other in the same order; so that in either case the prisms coincide and are equal.

Theorem II.—In any parallelopiped, the opposite planes are equal and parallel.

Fig. 137.

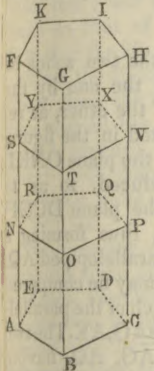


From the nature of the solid (4 Def.), the bases ABCD, EFGH are equal parallelograms, and their sides are parallel; therefore the planes AC, EG are parallel; and because AD is equal and parallel to BC, and AE is equal and parallel to BF, the ngle DAE = CBF, and the plane DAE is parallel to the plane CBF (10, 1); therefore also the parallelogram DAEH is equal to the parallelogram CBFG. It may in ike manner be demonstrated that the opposite parallelograms ABFE, DCGH are equal and parallel.

Cor. Any two opposite faces of a parallelopiped may be aken for its bases.

Theorem III.—In every prism ABCDE-FGHIK, the sections NOPQR, STVXY, made by parallel planes, are equal polygons.

Fig. 138.

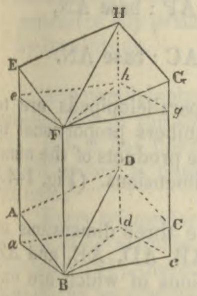


Because the parallel planes NOPQR, STVXY are cut by a third plane NOST; the sections NO, ST are parallel; and these lines are included between the parallels NS, OT, which are sides of the prism; therefore NO is equal to ST. For a like reason the sides OP, PQ, QR, &c. of the section NOPQR are respectively equal to the sides TV, VX, XY, &c. of the section STVXY. And besides, these equal sides being also parallel, the angles NOP, OPQ, &c. of the first section are respectively equal to the angles STV, TVX, &c. of the second section. Therefore the two sections NOPQR, STVXY are equal polygons.

Cor. Every section of an upright prism, by a plane parallel to the base, is equal to that base.

Theorem IV.—If a parallelopiped AG be cut by a plane passing through BD, FH, the diagonals of two of the opposite planes; it will be cut into two equivalent prisms ABDHEF, GHFBCD equal to one another.

Fig. 139.



Through B and F, the extremities of one of the sides, draw the planes B*adc*, F*ehg*, perpendicular to BF, to meet the three other sides of the solid in *a*, *d*, *c*, and in *e*, *h*, *g*. These sections are equal (3), because the planes are perpendicular to FB, and therefore parallel. They are also parallelograms (7, 1), because *a*B, *dc*, the opposite sides of the same section, are the intersections of two parallel planes ABFE, DCGH by the same plane. For a like reason, the figure B*ae*F is a parallelogram, as also the other lateral faces BFGC, *cdhg*, *adhe* of the solid B*adc*-F*ehg*. Therefore this solid is a prism (Def. 2), and it is a right prism, because BF is perpendicular to the plane of the base.

From the constitution of the figure, the right prism B*h* is divided into two right triangular prisms *a*B*d*-*e*F*h*, *c*B*d*-*g*F*h*, and it is now to be proved that the oblique triangular prism ABCD-EFGH is equal to the right triangular prism *a*B*d*-*e*F*h*. Since these two prisms have a common part ABD-*efh*, it is only necessary to prove that the remainders, viz. the solids B*a*AD*d*, F*e*FH*h* are equivalent to each other.

Because BAEF, B*ae*F are parallelograms, therefore AE = BF = *ae*; hence A*a* = E*e*. In like manner it may be proved that D*d* = H*h*. Conceive now that F*eh*, the base of the solid F*eh*, is placed on B*ad*, the base of the solid B*a*AD*d*; then, the point *e* falling on *a*, and *h* on *d*; the lines *e*E, *h*H will coincide with their equals *a*A, *d*D, because they are perpendicular to the same plane. Therefore, the two solids will coincide entirely, the one with the other; and hence it follows that the oblique prism BAD-FEH is equivalent to the right prism B*ad*-F*eh*.

In the same manner it may be demonstrated that the oblique prism BCD-FGH is equal to the right prism B*cd*-F*gh*. But the two prisms are equal (Cor. to 1), since they have the same altitude, BF and their bases are equal, they being halves of the same parallelogram; therefore the two triangular prisms BAD-FEH, BCD-FGH, which are equivalent to them, are also equivalent to each other.

Cor. Every triangular prism ABD-EFH is half a parallelopiped AG, having the same solid angle A with the same edges AB, AD, AE.

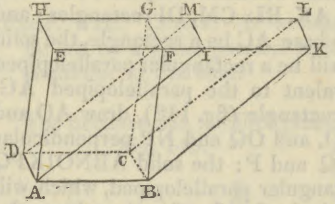
Scholium. Although the triangular prisms, into which the oblique parallelopiped is divided, are contained by equal planes, and have their solid angles equal, yet they cannot be made to coincide. The reason is, the plane angles about the corresponding solid angles are not placed in the same order. These solid angles are therefore symmetrical, and cannot be brought to coincide (18, 1). Two prisms, or two solids of any kind so constituted, are called *symmetrical solids*. An exact notion of their relation to each other may be acquired, by considering that any object, and its image reflected from a plane mirror, are symmetrical figures. They resemble each other exactly; but every part is placed in a reverse order; thus, the reflected image of a right hand is a left hand.

In symmetrical solids every circumstance on which the magnitude of each depends is the very same in both; hence it might be assumed, as an axiom in the geometry of solids, that they are equivalent.

Theorem V.—If two parallelopipeds AG, AL have a common base ABCD, and have their upper bases EFGH, IKLM in the same plane, and between the same parallels EK, HL; the two parallelopipeds are equivalent to each other.

There may be three cases, according as EI is greater or smaller than EF, or equal to it; but the demonstration is the same for them all. In the first place we shall prove that the triangular prism AEI-DHM is equal to the triangular prism BFK-CGL.

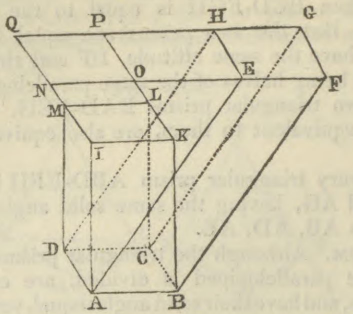
Fig. 140.



Since AE is parallel to BF, and HE to GF, the angle AEI = BFK, HEI = GFK, and HEA = GFB. Of these six angles, the three first form the solid angle E, and the three others form the solid angle F; therefore, since the plane angles are equal each to each, and similarly situated, the solid angles E and F are equal. Now, if the prism AEI-DHM be applied to the prism BFK-CGL, so that their bases AEI, BFK, which are equal, may coincide with each other; then, because the solid angle E is equal to the solid angle F, the side EH shall fall upon FG, and this is all that is necessary to prove that the two prisms coincide entirely; for the base AEI and the edge EH determine the prism AEM, and the base BFK and the edge FG determine the prism BFL (1); therefore the prisms are equal. Now, if from the solid AEL, the prism AEM be taken away, there will remain the parallelopiped AIL; and if from the same solid AEL, the prism BFL be taken away, there will remain the parallelopiped AEG; therefore the parallelopipeds AIL, AEG are equivalent to each other.

Theorem VI.—Two parallelopipeds upon the same base, and having the same altitude, are equivalent to one another.

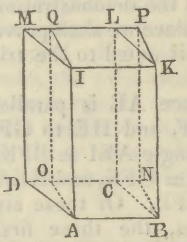
Fig. 141.



Let ABCD be the common base of the two parallelopipeds AG, AL, which, because they have the same altitude, will have their upper bases in the same plane. Then, because EF and AB are equal and parallel, as also IK and AB, EF is equal and parallel to IK (Cor. 2, 5, 1); for a similar reason GF is equal and parallel to LK. Let the sides EF, HG, as also the sides LK, IM, be produced, so as to form by their intersections the parallelogram NOPQ; it is manifest that this parallelogram is equal to each of the bases EFGH, IKLM. Now, if we suppose a third parallelopiped, which, with the same lower base ABCD, has for its upper base NOPQ, this third parallelopiped will be equivalent to the parallelopiped AG (4); for the same reason the third parallelopiped will be equivalent to the parallelopiped AL · therefore the two parallelopipeds AG, AL, which have the same base and the same altitude, are equivalent to one another.

Theorem VII.—Any parallelopiped may be changed into a rectangular parallelopiped having the same altitude, and an equivalent base. (Fig. 141 and 142.)

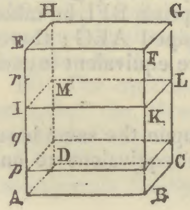
Fig. 142.



At the points A, B, C, D (fig. 141) let AI, BK, CL, DM, be drawn perpendicular to the plane ABCD, and terminating in the plane of the upper base; then, IK, KL, LM, MI, being joined, a parallelopiped AL will thus be formed, which will manifestly have its lateral faces AK, BL, CM, DI rectangles; and if the base AC be a rectangle, the solid AL will be a rectangular parallelopiped equivalent to the parallelopiped AG. But if ABCD be not a rectangle (fig. 142), draw AO and BN perpendicular to CD, and OQ and NP perpendicular to DC, meeting ML in Q and P; the solid ABNOIKPQ will manifestly be a rectangular parallelopiped, which will be equal to the parallelopiped AL; for they have the same base ABKI, and the same altitude, viz. AO; therefore the rectangular parallelopiped AP is equivalent to the parallelopiped AG (fig. 141), and they have the same altitude, and the base ABNO of the former is equivalent to the base ABCD of the latter.

Theorem VIII.—Two rectangular parallelopipeds AG, AL, which have the same base ABCD, are to each other as their altitudes AE, AI.

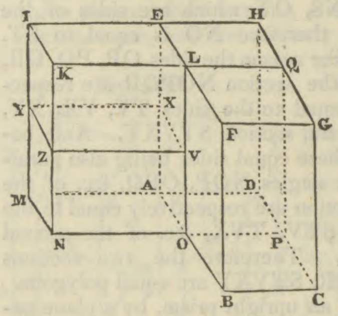
Fig. 143.



Suppose that the altitudes AE, AI are to each other as the numbers m and n, so that AE contains m such equal parts pq, &c. as AI contains n. Let AE and AI be divided into m and n equal parts respectively, and let planes pass through the points of division parallel to the base ABCD; thus the parallelopiped AG will be divided into m solids, which will also be parallelopipeds having equal bases (3) and equal altitudes, therefore they will be equal among themselves; and in like manner the parallelopiped AL will be divided into n equal solids; and as each of the solids in AG is equal to each of the solids in AL, the parallelopiped AG will contain m such equal parts as the parallelopiped AL contains n; therefore the parallelopiped AG will be to the parallelopiped AL as the number m to the number n, that is, as AE the altitude of the former to AI the altitude of the latter.

Theorem IX.—Two rectangular parallelopipeds AG, AK, which have the same altitude AE, are to each other as their bases ABCD, AMNO.

Fig. 144.



Let the two solids be placed, the one by the side of the other, as represented in the figure, and let the plane ONKI, be produced, so as to meet the plane DCGH in PQ, thus forming a third parallelopiped AQ, which may be compared with each of the parallelopipeds AG, AK. The two solids AG, AQ, having the same base ADHE, are to each other as their altitudes AB, AO (8); and, in like manner, the two solids AQ, AK having the same base AOLE, are to each other as their altitudes AD, AM; that is,

$$\text{solid AG} : \text{sol. AQ} = \text{AB} : \text{AO},$$
$$\text{sol. AQ} : \text{sol. AK} = \text{AD} : \text{AM};$$

but $\text{AB} : \text{AO} = \text{base AC} : \text{base AP}$ (3, 4, Part 1.)

and $\text{AD} : \text{AM} = \text{base AP} : \text{base AN}$,

therefore,

$$\text{sol. AG} : \text{sol. AQ} = \text{base AC} : \text{base AP},$$
$$\text{sol. AQ} : \text{sol. AK} = \text{base AP} : \text{base AN},$$

therefore, *ex æquo*,

$$\text{sol. AG} : \text{sol. AK} = \text{base AC} : \text{base AN}.$$

Theorem X.—Two rectangular parallelopipeds are to each other as the products of numbers proportional to their bases and altitudes, or as the products of the numbers which express their three dimensions. (Fig. 144.)

Let AG be a parallelopiped, the three dimensions of which are expressed by the lines AB, AD, AE, and AZ another parallelopiped the dimensions of which are expressed by the lines AO, AM, AX. Let the two solids AG, AZ be so placed, that their surfaces may have a common angle BAE; produce such of the planes as are necessary, so as to form a third parallelopiped AK, having the same altitude as the parallelopiped AG. By the last proposition,

$$\text{sol. AG} : \text{sol. AK} = \text{base AC} : \text{base AN},$$

and by the last theorem but one,

$$\text{sol. AK} : \text{sol. AZ} = \text{AE} : \text{AX};$$

but, considering the bases AC, AN as measured by numbers, as also the altitudes AE, AX, by 1 of Sect. III. Part I.

$$\text{base AC} : \text{base AN} = \text{AE} \times \text{base AC} : \text{AE} \times \text{base AN},$$
$$\text{and AE} : \text{AX} = \text{AE} \times \text{base AN} : \text{AX} \times \text{base AN},$$

therefore,

$$\text{sol. AG} : \text{sol. AK} = \text{AE} \times \text{base AC} : \text{AE} \times \text{base AN},$$
$$\text{sol. AK} : \text{sol. AZ} = \text{AE} \times \text{base AN} : \text{AX} \times \text{base AN},$$

therefore, *ex æquo*,

$$\text{sol. AG} : \text{sol. AZ} = \text{AE} \times \text{base AC} : \text{AX} \times \text{base AN};$$

which proportion, by substituting for the bases AC, AN their numerical values $AB \times AD$ and $AO \times AM$, becomes sol. AG : sol. $AZ = AB \times AD \times AE : AO \times AM \times AX$.

Scholium. Hence it appears that the product of the base of a rectangular parallelopiped by its altitude, or the product of its three dimensions, may be taken as its numerical measure; and it is upon this principle that all other solids are estimated. When two parallelopipeds are compared by means of their bases and altitudes, their bases must be considered as measured by the same superficial unit, and their altitudes by the same linear unit; thus, if P and Q denote two parallelopipeds, and the base of P contain three such equal spaces as that of Q contains four; and the altitude of P contains two such equal lines as that of Q contains five, then $P : Q = 3 \times 2 : 4 \times 5 = 6 : 20$.

If all the dimensions of each solid be used in comparing them, then, the same linear unit must be employed in estimating all the dimensions of both solids; thus, if the length, breadth, and height of the solid P be 4, 3, and 6 linear units, respectively; and those of Q, 7, 2, and 5, of the same units; then $P : Q = 4 \times 3 \times 6 : 7 \times 2 \times 5 = 72 : 70$.

As lines are compared by considering how often each contains some other line taken as a measuring unit, and surfaces, by considering how often each contains a square whose side is that unit; so solids may be compared, by considering how often each contains a cube, the side or edge of which is the same linear unit. Accordingly, the dimensions of the parallelopipeds P and Q being as above, the proportion $P : Q = 72 : 70$ may be considered as indicating that P contains 72 such equal cubes as Q contains 70.

The magnitude of a solid, its bulk, or its extension, constitutes its *solidity*, or its *content;* thus, we say, that the solidity or the content of a rectangular parallelopiped is equal to the product of its base by its altitude, or to the product of its three dimensions.

Theorem XI.—The solidity of any parallelopiped, or in general of any prism, is equal to the product of its base by its altitude.

1. Any parallelopiped is equivalent to a rectangular parallelopiped of the same altitude, and an equivalent base (7); and it has been shown that the solidity of such a parallelopiped is equal to the product of its base by its altitude.

2. Every triangular prism is the half of a parallelopiped of the same altitude, but having its base double that of the prism (3); therefore the solidity of the prism is half that of the parallelopiped, or it is half the product of the base of the parallelopiped by its altitude, that is, it is equal to the product of the base of the prism by its altitude.

3. Any other prism may be divided into as many triangular prisms as there can be triangles in the polygon which forms its base; but the solidity of each prism is equal to the product of its base by their common altitude; therefore the solidity of the whole prism is equal to the product of the sum of all their bases by the common altitude, or it is equal to the product of the base of the prism, which is the sum of them all, by its altitude.

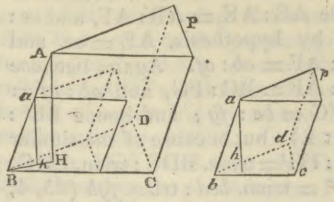
Cor. Two prisms having the same altitude are to each other as their bases; and two prisms having the same base are to each other as their altitudes.

Note. The cube of a line AB is expressed thus; $AB \times AB \times AB$, but more commonly by AB^3.

Theorem XII.—Similar prisms are to one another as the cubes of their homologous sides.

Let P and *p* be two prisms, of which BC, *bc* are the homologous sides; the prism P is to the prism *p* as a cube on the line BC to a cube on *bc*.

Fig. 145.



From A and *a*, homologous angles of the two prisms, draw AH, *ah* perpendicular to their bases BCD, *bcd*. Join BH; take $Ba = ba$, and in the plane BHA draw *ah* perpendicular to BH; then *ah* shall be perpendicular to the plane CBD (13, 1), and equal to *ah*, the altitude of the other prism; for if the solid angles B and *b* were applied the one to the other, the planes which contain them, and consequently the perpendiculars *ah*, *ah* would coincide (Schol. 18, 1).

Now, because of the similar triangles ABH, *abh*, and the similar figures AC, *ac*,

$$AH : ah = AB : ab = BC : bc;$$

and because of the similar bases,

$$\text{base } BCD : \text{base } bcd = BC^2 : bc^2 \text{ (25, 4, Part I.)}$$

From these two proportions, by considering all the quantities, as expressed by numbers (by 11, 3, Part I.),

$$AH \times \text{base } BCD : ah \times \text{base } BCD = BC^3 : bc \times BC^2,$$
$$ah \times \text{base } BCD : ah \times \text{base } bcd = bc \times BC^2 : bc^3,$$

therefore, *ex æquo*,

$$AH \times \text{base } BCD : ah \times \text{base } bcd = BC^3 : bc^3.$$

But $AH \times$ base BCD expresses the content of the prism P; and $ah \times$ base *bcd* expresses that of the other prism *p;* therefore

$$\text{prism } P : \text{prism } p = BC^3 : bc^3.$$

Cor. Similar prisms are to one another in the triplicate ratio of their homologous sides. Let S and *s* denote the homologous sides of two similar prisms P and *p*. It is manifest that

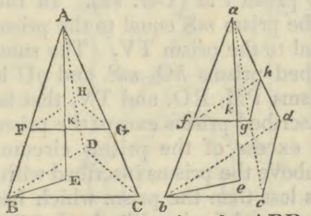
$$S^3,\ S^2s,\ Ss^2,\ s^3,$$

are four continual proportionals; therefore (Def. 11, Sect. III. Part I.), the ratio of S^3, the first, to s^3, the last, is the triplicate of the ratio of S^3, the first, to S^2s, the second; now, by the proposition, $P : p = S^3 : s^3$, and the ratio of S^3 to S^2s is the same as the ratio of S to *s;* therefore, the ratio of P to *p* is triplicate of the ratio of S to *s*.

Prop. XIII. Theor.—If a triangular pyramid A-BCD be cut by a plane parallel to its base, the section FGH is similar to the base.

For because the parallel planes BCD, FGH are cut by a third plane ABC, the sections FG, BC are parallel (7, 1). In like manner it appears that FH is parallel to BD; therefore the angle HFG is equal to the angle DBC (10, 1.) And because the triangle ABC is similar to the triangle AFG, and the triangle ABD is similar to the triangle AFH, we have

Fig. 146.



$$BC : BA = FG : FA, \text{ and } BA : BD = FA : FH.$$

Therefore, *ex æquali*, $BC : BD = FG : FH$; now the angle DBC has been shown to be equal to the angle HFG; therefore the triangles DBC, HFG are equiangular (20, 4, Part I.)

Prop. XIV. Theor.—If two triangular pyramids A-BCD, *a-bcd*, which have equivalent bases and equal altitudes, be cut by planes that are parallel to the bases, and at equal distances from them; the sections FGH, *fgh* will be equal. (Fig. 146.)

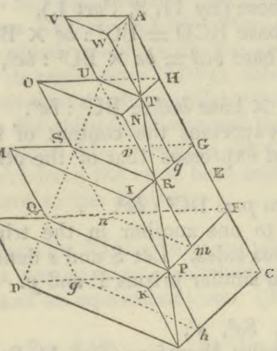
Draw AKE, *ake* perpendicular to the bases BCD, *bcd*, meeting the cutting planes in K and *k*; then, because of the parallel planes, we have $AE : AK = AB : AF$, and $ae : ak = ab : af$ (15, 1); but, by hypothesis, $AE = ae$, and $AK = ak$; therefore, $AB : AF = ab : af$. Again, because of similar triangles, $AB : AF = BC : FG$, and $ab : af = bc : fg$; therefore $BC : FG = bc : fg$; and hence $BC^2 : FG^2 = bc^2 : fg^2$ (23, 4, Part I.); but because of the similar triangles BDC, FHG, $BC^2 : FG^2 =$ trian. BDC : trian. FHG, and in like manner $bc^2 : fg^2 =$ trian. *bcd* : trian. *fgh* (25, 4, Part I.), therefore

trian. BCD : trian. FGH = trian. *bcd* : trian. *fgh*.

Now, trian. BCD = trian. *bcd* (by hypothesis), therefore the triangle FHG is equal to the triangle *fhg*.

Theorem XV.—A series of prisms of the same altitude may be circumscribed about any pyramid ABCD, such, that the sum of the prisms shall exceed the pyramid by a solid less than any given solid Z.

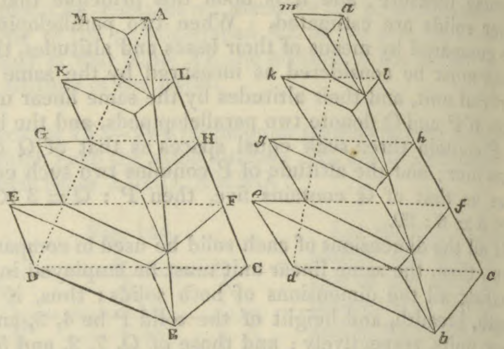
Fig. 147.



Let Z denote a prism standing on the same base with the pyramid, viz. the triangle BCD, and having for its altitude the perpendicular drawn from a certain point E in the line AC upon the plane BCD. It is evident that CE multiplied by a certain number *m* will be greater than AC; divide CA into as many equal parts as there are units in *m*, and let these be CF, FG, GH, HA, each of which will be less than CE. Through each of the points F, G, H, let planes be made to pass parallel to the plane BCD, making with the sides of the pyramid the sections FPQ, GRS, HTU, which will be all similar to one another, and to the base BCD (13). From the point B draw in the plane of the triangle ABC the straight line BK parallel to CF, meeting FP produced in K. In like manner, from D draw DL parallel to CF, meeting FQ in L; join KL, and it is plain that the solid KBCDLF is a prism. By the same construction let the prisms PM, RO, TV be described. Also let the straight line IP, which is in the plane of the triangle ABC, be produced till it meet BC in *h*; and let the line MQ be produced till it meet DC in *g*. Join *hg*, then *h*C*g* QFP is a prism; and is equal to the prism PM (Cor. 11). In the same manner is described the prism *m*S equal to the prism RO, and the prism *q*U equal to the prism TV. The sum, therefore, of all the inscribed prisms *h*Q, *m*S, and *q*U is equal to the sum of the prisms PM, RO, and TV, that is, to the sum of all the circumscribed prisms except the prism BL; wherefore, BL is the excess of the prisms circumscribed about the pyramid above the prisms inscribed within it. But the prism BL is less than the prism which has the triangle BCD for its base, and for its altitude the perpendicular from E upon the plane BCD, which prism is, by hypothesis, equal to the given solid Z; therefore the excess of the circumscribed above the inscribed prisms is less than the solid Z. But the excess of the circumscribed prisms above the inscribed is greater than their excess above the pyramid ABCD, because ABCD is greater than the sum of the inscribed prisms; much more therefore is the excess of the circumscribed prisms above the pyramid less than the solid Z. A series of prisms of the same altitude has therefore been circumscribed about the pyramid ABCD exceeding it by a solid less than the given solid Z.

Prop. XVI. Theor.—Pyramids that have equal bases and altitudes are equal to one another.

Fig. 148.

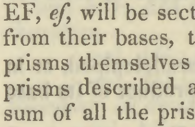


Let A-BCD, *a-bcd* be two pyramids that have equal bases BCD, *bcd*, and equal altitudes; viz. the perpendiculars drawn from the vertices A and *a* upon the planes BCD, *bcd*, the pyramid A-BCD is equal to the pyramid *a-bcd*.

For if they are not equal, let Z represent the solid which is equal to the excess of one of them, *a-bcd*, above the other A-BCD; and let a series of prisms CE, FG, HK, LM, of the same altitude be circumscribed about the pyramid A-BCD, so as to exceed it by a solid less than Z, which is always possible (15); also let a series of prisms, *ce*, *fg*, *hk*, *lm*, equal in number to the other, and of the same altitude, be circumscribed about the pyramid *a-bcd*. And because the pyramids have equal altitudes, and the number of prisms described about each is the same, the altitudes of the prisms will be all equal, and the bases of the corresponding prisms in the two pyramids, as EF, *ef*, will be sections of the pyramids at equal distances from their bases, therefore they are equal (14), and the prisms themselves are equal (1), and the sum of all the prisms described about the one pyramid is equal to the sum of all the prisms described about the other pyramid. To abridge, put P and *p* to denote the pyramids A-BCD, and *a-bcd* respectively, and Q and *q* to express the sums of the prisms described about them. Then, because by hypothesis $Z = p - P$, and by construction $Z > Q - P$, therefore $p - P > Q - P$, hence *p* must be greater than Q; but Q is equal to *q*, therefore *p* must be greater than *q*, that is, the pyramid *p* is greater than *q*, the sum of the prisms described about it, which is impossible; therefore the pyramids P, *p* are not unequal, that is, they are equal.

Theorem XVII.—Every prism having a triangular base may be divided into three pyramids that have triangular bases, and that are equal to one another.

Fig. 149.



Let ABC, DEF be the opposite bases of a triangular prism. Join AE, EC, CD; and because ABED is a parallelogram, of which AE is the diameter, the triangle ADE is equal to the triangle ABE; therefore the pyramid of which the base is the triangle ADE and vertex the point C, is equal to the pyramid of which the base is the triangle ABE, and vertex the point C. But the pyramid of which the base is the triangle ABE and vertex the point C, that is, the pyramid ABCE, is equal to the pyramid DEFC (16), for they have equal bases, viz. the triangles ABC, DFE, and the same altitude, viz. the altitude of the prism ABCDEF. Therefore, the three pyramids ADEC, ABEC, DFEC are equal to one another; but these pyramids make up the whole prism ABCDEF; therefore, the prism ABCDEF is divided into three equal pyramids.

Cor. 1. From this it is manifest that every pyramid is the third part of a prism which has the same base and the same altitude with it; for if the base of the prism be any other figure than a triangle, it may be divided into prisms having triangular bases.

Cor. 2. Pyramids having equal altitudes are to one another as their bases; because the prisms upon the same bases, and of the same altitude, are to one another as their bases.

SECT. III.—OF CYLINDERS, CONES, AND THE SPHERE.

Definitions.

I. A *Cylinder* is a solid figure described by the revolution of a right-angled parallelogram about one of its sides, which remains fixed.

The *Axis* of the cylinder is the fixed straight line about which the parallelogram revolves.

The *Bases* of the cylinder are the circles described by the two revolving opposite sides of the parallelogram.

II. A *Cone* is a solid figure described by the revolution of a right-angled triangle about one of the sides containing the right angle, which side remains fixed.

The *Axis* of the cone is the fixed line about which the triangle revolves.

The *Base* of the cone is the circle described by that side containing the right angle which revolves.

III. A *Sphere* is a solid figure described by the revolution of a semicircle about a diameter.

The *Axis* of a sphere is the fixed line about which the semicircle revolves.

The *Centre* of a sphere is the same with that of the semicircle.

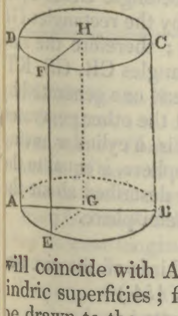
The *Diameter* of a sphere is any straight line which passes through the centre, and is terminated both ways by the superficies of the sphere.

IV. *Similar* cones and cylinders are those which have their axes and diameters of their bases proportional.

Theorem I. If from any point E in the circumference of the base of a cylinder ABCD, a perpendicular EF be drawn to the plane of the base AEB; the straight line EF is wholly in the cylindric superficies.

Let GH be the axis, and AGHD the rectangle, which by its revolution describes the cylinder. Because HG is perpendicular to AG in every position of the revolving rectangle, it is perpendicular to the plane of the circle described by AG; and because AD, the line which describes the cylindric superficies, is parallel to GH, it is also perpendicular to the plane of that circle (5, 1). Now when by the revolution of the rectangle AGHD the point A coincides with the point E, the line EF will coincide with AD, and thus will be wholly in the cylindric superficies; for otherwise two perpendiculars might be drawn to the same plane, from the same point, which is impossible (2 Cor. 4, 1).

Fig. 150.

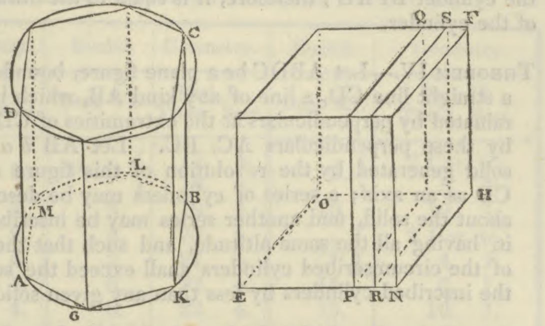


Theorem II.—A cylinder and a parallelopiped having equivalent bases, and the same altitude, are equal to one another.

Geometry of Solids.

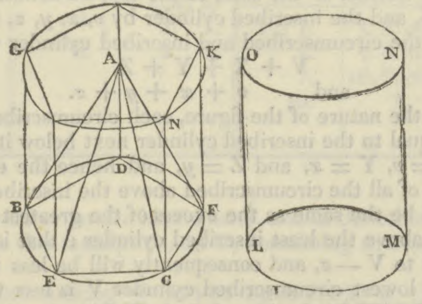
Let ABCD be a cylinder and EF a parallelopiped having equivalent bases, viz. the circle AGB and the parallelogram EH, and having also equal altitudes; the cylinder ABCD is equal to the parallelopiped EF. If not, let them be unequal; and first let the cylinder be less than the parallelopiped EF; and from the parallelopiped EF let there be cut off a part EQ by a plane PQ parallel to NF, equal to the cylinder ABCD. In the circle AGB inscribe the polygon AGKBLM that shall differ from the circle by a space less than the parallelogram PH (1 Cor. 2, 6, P. I.), and cut off from the parallelogram EH a part OR equal to the polygon AGKBLM, then it is manifest that the parallelogram OR is greater than the parallelogram OP, therefore the point R will fall between P and N. On the polygon AGKBLM let an upright prism be constituted of the same altitude with the cylinder, which will therefore be less than the cylinder, because it is within it (1); and if through the point R a plane RS parallel to NF be made to pass, it will cut off the parallelopiped ES equal to the prism AGBC, because its base is equal to that of the prism, and its altitude is the same. But the prism AGBC is less than the cylinder ABCD, and the cylinder ABCD is equal to the parallelopiped EQ, by hypothesis; therefore, ES is less than EQ, and it is also greater, which is impossible. The cylinder ABCD therefore is not less than the parallelopiped EF; and in the same manner it may be shown not to be greater than EF, therefore they are equal.

Fig. 151.



Theorem III.—If a cone and cylinder have the same base and the same altitude; the cone is the third part of the cylinder.

Fig. 152.



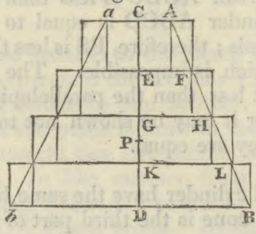
Let the cone ABCD and the cylinder BFKG have the same base, viz. the circle BCD, and the same altitude, viz. the perpendicular from the point A upon the plane BCD; the cone ABCD is the third part of the cylinder BFKG. If not, let the cone ABCD be the third part of another cylinder LMNO having the same altitude with the cylinder BFKG; but let the bases BCD, LIM be unequal, and first let BCD be greater than LIM. Then, because the circle BCD is greater than the circle LIM, a polygon may be inscribed in BCD that shall differ from it less than LIM does (1 Cor. 2, 6, P. I.), and which therefore will be greater than

LIM. Let this be the polygon BECFD, and upon BECFD let there be constituted the pyramid ABECFD, and the prism BCFKHG. Because the polygon BECFD is greater than the circle LIM, the prism BCFKHG is greater than the cylinder LMNO, for they have the same altitude, but the prism has the greater base. But the pyramid ABECFD is the third part of the prism BCFHG (17, 1); therefore it is greater than the third part of the cylinder LMNO. Now the cone ABECFD is by hypothesis the third part of the cylinder LMNO; therefore, the pyramid ABECFD is greater than the cone ABCD, and it is also less, because it is inscribed to the cone, which is impossible. Therefore the cone ABCD is not less than the third part of the cylinder BFKG. And in the same manner, by circumscribing a polygon about the circle BCD, it may be shown, that the cone ABCD is not greater than the third part of the cylinder BFKG; therefore, it is equal to the third part of the cylinder.

Theorem IV.—Let ABDC be a plane figure, bounded by a straight line CD, a line of any kind AB, which is terminated by perpendiculars at the extremities of CD, and by these perpendiculars AC, BC. Let AB $b\,a$ be a solid generated by the revolution of this figure about CD as an axis; a series of cylinders may be described about the solid, and another series may be inscribed in it, having all the same altitude, and such that the sum of the circumscribed cylinders shall exceed the sum of the inscribed cylinders by less than any given solid S.

Let S denote a solid which is a cylinder, having Bb for the diameter of its base, and DP for its height. Suppose the fixed axis CD to be divided into a number of equal parts DK, KG, GE, EC, each less than DP. In the plane of the figure ABDC, draw perpendiculars EF, GH, KL to meet the line AB in F, H, L. Construct the inscribed rectangles AE, FG, HK, LD, also the circumscribed rectangles CF, EH, GL, KB. By the rotation of the plane figure about the axis CD, these rectangles will evidently generate a series of cylinders inscribed in the solid, and another series described about it. Let the circumscribed cylinders, reckoned from the bottom of the solid to the top, be denoted by V, X, Y, Z, and the inscribed cylinder by v, x, y, z, then the sums of the circumscribed and inscribed cylinder will be

Fig. 153.



$$V + X + Y + Z,$$

and $$v + x + y + z.$$

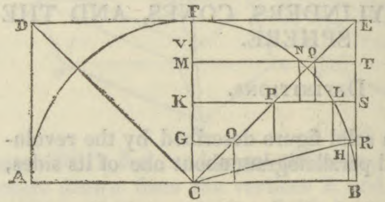
Now by the nature of the figure, each circumscribed cylinder is equal to the inscribed cylinder next below it; therefore $X = v$, $Y = x$, and $Z = y$, and hence the excess of the sum of all the circumscribed above the inscribed cylinders will be the same as the excess of the greatest circumscribed above the least inscribed cylinder; that is, it will be equal to $V - z$, and consequently will be less than V; but the lowest circumscribed cylinder V is less than the solid S, because it has the same base (viz. the circle having for its diameter B b), and a less altitude KD, by construction; therefore the excess of the series of circumscribed above the series of inscribed cylinders is less than the given solid S.

Cor. The difference between the solid AB ba and either of the two series of cylinders will be less than the greatest circumscribed cylinder: For the solid AB ba is greater than the one series of cylinders and less than the other; therefore it will differ from either series by a quantity less than the difference between the two.

Theorem V.—If a cone and hemisphere have equal bases and altitudes, and if a series of cylinders be described about the cone, and another series be inscribed in the hemisphere, and the cylinders have all the same altitude; the sum of the two series will be equal to a cylinder having the same base and altitude as the hemisphere.

Let AFB be a semicircle, and CFDA, CFEB, squares described on the radius CF, and let CE be the diagonal of one of the squares BF: Let CF be divided into any number of equal parts CG, GK, KM, MF; and let perpendiculars be drawn through the points of division, meeting the diagonal CE, in the points O, P, Q; the quadrantal arc BF in the points H, L, N; and the side of the square in the points R, S, T; construct the rectangles CO, GP, KQ, ME, which will circumscribe the triangle CFE; construct also the rectangles CH, GL, KN, which will be inscribed in the quadrant CFB. Suppose now the plane of the square to revolve about its side CF as an axis; the triangle CFE will then generate a cone, which will have DE for the diameter of its base, and C for its vertex; the quadrant CFB will generate a hemisphere, having for its base a circle of which AB is a diameter; and the square CBEF will generate a cylinder, having the same base and altitude as the hemisphere: also, the rectangles described about the triangle CFE will manifestly generate a series of cylinders circumscribing the cone; the rectangles inscribed in the quadrant will generate a series of cylinders inscribed in the hemisphere; and the rectangles CR, GS, KT, ME will generate a series of cylinders which will compose a cylinder having the same base and altitude as the hemisphere.

Fig. 154.



The triangles CFE, CGO are manifestly similar, and $CF = FE$; therefore $CG = GO$. In like manner, it may be proved that $CK = KP$ and that $CM = MQ$.

Join CH, and because CGH is a right-angled triangle, a circle described with CH as a radius will be equal to two circles described with CG and GH as radii (2 Cor. 4, 6, Part I.), but $CG = GO$, and $CH = GR$; therefore a circle described with GR as a radius will be equal to two circles described with GO and GH as radii; hence again it follows, that the cylinder generated by the rectangle CR will be equal to both the cylinders generated by the rectangles CO and CH, for they have all the same altitude, and the base of the first is equal to the sum of the bases of the other two. It may be demonstrated in the same manner that the cylinder generated by the rectangle GS is equal to the sum of the cylinders generated by the rectangles GP and GL, and the same of all the rest; therefore the sum of the cylinders generated by the rectangles CR, GS, KT, ME is equal to the two series of cylinders, one generated by the rectangles CO, GP, KQ, ME, and the other generated by the rectangles CH, GL, KN; that is, a cylinder having the same base and altitude as the hemisphere, is equal to the sum of the two series of cylinders, one described about the cone, and the other described in the hemisphere.

Theorem VI.—Every sphere is two thirds of the circumscribing cylinder. (Fig. 154.)

Let a figure be constructed exactly as is last proposition; and to abridge, let C denote the cone, c the series of cylinders described about it, H the hemisphere, h the cylinders described in it, and K the cylinder having the same base and altitude as the hemisphere, or cone. Moreover, put d

or the difference between the cone and its circumscribed cylinders, and d' for the difference between the hemisphere and its inscribed cylinders; then we have

$$C + d = c, \text{ and } H = h + d',$$

and adding equals to equals,

$$C + H + d = c + h + d'.$$

But $c + h = K$ (5); therefore, $C + H + d = K + d'$, nd $C + H + d - d' = K$, also $C + H = K + d' - d$. Hence it appears that the difference between $C + H$ and K is equal to the difference between d and d'. Now d is ess than the cylinder generated by the rotation of the rectngle ME (Cor. to Prop. 4), and d' is less than the cylinder enerated by the rectangle CR, which is equal to ME; herefore the difference between d and d' must be less than the same rectangle; hence the difference between $C + H$ and K is less than the cylinder generated by the revolution of the rectangle ME, or is less than a cylinder having the same base as the cone, and the line FM for its altitude. From this we may infer, that $C + H$ is exactly equal to K; for if there can be any difference, let it be a cylinder having the same base as the cone, and its altitude equal to FV; then FM must be greater then FV; but the number of parts into which FC is divided may be so great that FM may be less than FV; therefore $C + H$ cannot be unequal to K; and since $C + H = K$, and $C = \frac{1}{3}K$ (3), therefore $H = \frac{2}{3}K$; that is, the hemisphere is two thirds of its circumscribing cylinder; and taking the doubles of these, the whole sphere is two thirds of its circumscribing cylinder.

(R.)

GEORGE I. II. III. and IV. kings of Great Britain. See BRITAIN.

GEORGE, or *Knights of* ST GEORGE, has been the denomination of several military orders, of which that of the Garter is one of the most illustrious.

King GEORGE'*s Islands* are two islands in the South Seas, ying in west longitude 144. 56. and south latitude 14. 28. ee POLYNESIA.

GEORGE, ST, or GEORGE *of Cappadocia*, a name by which everal orders, both military and religious, are denominated. It took its rise from a saint or hero famous throughut all the East, called by the Greeks Μεγαλομαρτυς, or the Great Martyr.

On some medals of the emperors John and Manuel Comneni may be seen the figure of St George armed, holding a sword or javelin in one hand, and in the other a buckler, with this inscription, an O, containing therein A, and ΓΕ$\overset{\text{P}}{\underset{\text{O}}{—}}$ΓΙΟC, making Ο ΑΓΙΟΣ ΓΕΟΡΓΙΟΣ, or the Holy George. He is generally represented on horseback, being supposed to have frequently engaged in combat in that manner. He is highly venerated throughout Armenia, Muscovy, and all the countries which adhere to the Greek ritual; from the Greek his worship has long ago been received into that of the Latin church; and England and Portugal have both chosen him as their patron saint.

Great difficulties have been raised about this saint or hero, whose very existence has been called in question. Dr Heylin, who wrote most largely concerning him, con-

George.

cluded by giving him up entirely, and supposing him only a symbolical device; whilst Dr Pettingal turned him into a mere Basilidian symbol of victory. But Mr Pegg, in a paper in the *Archæologia*, attempted to restore the hero; and, finally, Mr Gibbon sunk him into an Arian bishop in the reigns of Constantius and Julian.

GEORGE *the Cappadocian* was so surnamed, according to some, from his parents or education, and was born at Epiphania, in Cilicia, in a fuller's shop. From this obscure and servile origin he raised himself by the talents of a parasite; and the patrons whom he had assiduously flattered procured for their worthless dependent a lucrative commission or contract to supply the army with bacon. His employment was mean, and he rendered it infamous. He accumulated wealth by the basest arts of fraud and corruption; but his malversations were so notorious that he was at length compelled to escape from the pursuit of justice. After this disgrace, in which he appears to have saved his fortune at the expense of his character, he embraced, with real or affected zeal, the profession of Arianism. From the love or the ostentation of learning, he collected a valuable library of history, rhetoric, philosophy, and theology; and the choice of the prevailing faction promoted George of Cappadocia to the throne of Athanasius. His conduct in this station is represented by historians as polluted by cruelty and avarice, and his death is considered as a just punishment for the enormities of his life, amongst which Mr Gibbon seems to rank his enmity to the gods.

The immediate occasion of his death, however, as narrated by ecclesiastical writers, does not appear calculated to add any stain to his memory. There was in the city of Alexandria a place in which the heathen priests had been accustomed to offer human sacrifices. This place, as being of no use, Constantius gave to the church of Alexandria, and George the bishop issued orders that it should be cleared in order to build a Christian church on the spot. In doing this they discovered an immense subterranean cavern, in which the heathen mysteries had been performed, and where there were many human skulls. These, and other things which they found in the place, the Christians brought out and exposed to public ridicule. Provoked at this exhibition, the heathens suddenly took arms, and rushing upon the Christians, killed many of them with swords, clubs, and stones; some also they strangled, and several they crucified. The Christians, therefore, proceeded no farther in clearing the temple; but the heathens, pursuing their advantage, seized the bishop whilst he was in the church, and threw him into prison. The next day they dispatched him; and then fastening the body to a camel, they dragged it about the streets all day, and in the evening burned the corpse and the camel together. This fate, according to Sozomen, the bishop owed in part to his haughtiness whilst in favour with Constantius; and some think that the friends of Athanasius were concerned in this murder; but the former ascribes it chiefly to the inveteracy of the heathens, whose superstitions he had been active in abolishing.

This George, the Arian bishop of Alexandria, was a man of letters, and had a valuable library, which Julian ordained to be seized for his own use. In his orders concerning the collection, he says that many of the books were on philosophical and rhetorical subjects, though many of them related to the doctrine of the impious Galileans, as he affected to call the Christians. "These books," says he, "I could wish to have utterly destroyed; but lest books of value should be destroyed along with them, let those also be carefully sought for."

But Mr Gibbon gives a different version of the affair of George's murder, which he relates with different circumstances. "The Pagans," says he, "excited his devout avarice; and the rich temples of Alexandria were either pillaged or insulted by the haughty prelate, who exclaimed, in a loud and threatening tone, 'How long will these sepulchres be permitted to stand?' Under the reign of Constantius, he was expelled by the fury, or rather by the justice, of the people; and it was not without a violent struggle that the civil and military powers of the state could restore his authority, and gratify his revenge. The messenger who proclaimed at Alexandria the accession of Julian, announced the downfall of the archbishop. George, with two of his obsequious ministers, Count Diodorus, and Darcontius, master of the mint, was ignominiously dragged in chains to the public prison. At the end of twenty-four days, the prison was forced open by the rage of a superstitious multitude, impatient of the tedious forms of judicial proceedings. The enemies of gods and men expired under their cruel insults; the lifeless bodies of the archbishop and his associates were carried in triumph through the streets on the back of a camel; and the inactivity of the Athanasian party was esteemed a shining example of evangelical patience. The remains of these guilty wretches were thrown into the sea; and the popular leaders of the tumult declared their resolution to disappoint the devotion of the Christians, and to intercept the future honours of these martyrs, who had been punished, like their predecessors, by the enemies of their religion. The fears of the Pagans were just, and their precautions ineffectual. The meritorious death of the archbishop obliterated the memory of his life. The rival of Athanasius was dear and sacred to the Arians, and the seeming conversion of these sectaries introduced his worship into the bosom of the Catholic church. The odious stranger, disguising every circumstance of time and place, assumed the mask of a martyr, a saint, and a Christian hero; and the infamous George of Cappadocia has been transformed into the renowned St George of England, the patron of arms, of chivalry, and of the Garter."

Knights of ST GEORGE. See GARTER. There have been various other orders under this denomination, most of which are now extinct, particularly one founded by the Emperor Frederick III. in the year 1470, to guard the frontiers of Bohemia and Hungary against the Turks; and another, called St George of Alfama, founded by the kings of Aragon; and another in Austria and Carinthia.

Religious of ST GEORGE. Of these there were different orders and congregations, particularly canons regular of St George in Alga, at Venice, established by authority of Pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartolomeo Colonna, who preached in 1396 at Padua, and some other villages in the state of Venice. Pope Pius V. in 1570, gave these canons precedence over all other religious orders.

ST GEORGE, a fort and town of Asia, in the peninsula on this side the Ganges, and on the coast of Coromandel, belonging to the British. It is otherwise called *Madras*, and by the natives *Chilipatam*. See MADRAS.

ST GEORGE'S, the largest of the Bermuda or Summer Islands. Long. 65. 10. W. Lat. 32. 30. N.

Cross of ST GEORGE, a red cross in a field argent, forming part of the British standard.

GEORGE, LAKE, a lake in the state of New York, North America. It lies to the south of Lake Champlain, and communicates with it. Lake George is a romantic and beautiful sheet of water, about thirty-seven miles in length, and from one to four or five miles in breadth. It is remarkable for the transparency of its waters, which contain an abundance of excellent fish. The lake is in general very deep, and interspersed with numerous islands, one of which, Diamond Island, formerly possessed a fort.

GEORGE'S CHANNEL, a dangerous passage in the Eastern Seas, between the great Nicobar Island and the others.

Georgia.

The danger in this passage arises from the rapidity with which the tide runs, which is at the rate of about five miles an hour, and from rocks, so that it is not safe for any vessel to enter it.

GEORGETOWN, the chief town of Prince of Wales' Island, which is well built, having spacious streets running at right angles. It is bounded on the north and east by the sea, and on the west by a high road.

GEORGETOWN, a post-town and port of entry in Washington county, district of Columbia, in North America. It is situated on the north-eastern bank of the Potomac, about two hundred miles from its mouth, and three from Washington, the capital. It possesses several public buildings, institutions, places of public worship, schools, and the like, and is a place of considerable trade. In consequence of the difficulties of navigation occasioned by a bar about three miles below the town, a considerable part of the produce is sent to Alexandria for exportation. Georgetown College is a Catholic institution, under the direction of the incorporated Catholic clergy of Maryland. The population of this town in 1830 amounted to 8441.

GEORGETOWN, a post-town, port of entry, and capital of Georgetown district, in South Carolina. It is situated on the west side of Winyaw Bay, about sixty miles north-north-east of Charleston. It enjoys some trade, and possesses the usual public buildings, together with a population of about 2000.

GEORGIA, or GRUSIA. This extensive tract of country, which is situated between the Black and the Caspian Seas, now forms a province of Russia by the encroachments of that power on the side of Persia. It is diversified by great inequalities of surface; but contains many fertile and beautiful valleys, which are finely contrasted with the mountainous character of the regions of Caucasus. The hills are clothed with the finest woods, consisting of oak, ash, chestnut, beech, and elm. Some vines grow perfectly wild, producing the finest grapes; and the wines produced have always, according to the report of Sir R. K. Porter, been esteemed for softness, lightness, and delicacy of taste. The valleys are extremely fertile, producing cotton, as well as the finest European fruit trees, and abundance of hemp, flax, rice, millet, barley, and wheat. The country is copiously watered by the rivers which flow from the mountains, and produce great variety of delicious fish. Pheasants, wild fowl of every kind, antelopes, deer, sheep, with all sorts of domestic cattle, are found in the valleys. In the mountains are found mines of gold, silver, and other minerals. The habits of the people are such as might be expected in their low state of civilization. A struggle for independence was long maintained by the Georgians against the inroads of Persia. But it was at last reduced into a province of that vast monarchy, and it was afterwards the arena of the Persian and Russian wars, by which the country was ravaged; and the people, far from being naturally industrious, appeared to despise every pursuit which required labour. They neglected agriculture, and were often engaged in intestine wars, or in forays on their neighbours for the sake of plunder; and were frequently exposed, in consequence, to severe retaliation from the Lesghees, a barbarous tribe, subsisting, like most of the mountain tribes of Asia, by pillage. But about the year 1800 it was reduced into a province of the Russian empire; and, under the iron rule of that despotic power, order has been re-established, the traveller has been protected from robbery, commerce and agriculture begin to be followed, and a favourable revolution appears to have taken place in the habits and manners of the people. Sir R. K. Porter, who has given an interesting account of these newly-conquered provinces, mentions that the different European governors have generally endeavoured to conciliate the people and the nobles, and that the country being now effectually guarded from the destructive inroads of plundering banditti or foreign enemies, the nobles begin to feel the importance of the station they hold in the country; whilst they have been still further countenanced by the distribution of medals and orders of distinction amongst the leading men, with titles also and commissions of military rank in the Russian armies. The Georgians are tall and well formed. The Georgian noble is distinguished by a sombre cast of visage, which, though stern, is of a fine contour, and harmonizes well with the minuteness of his figure, and the style of his dress, which consists of an under garment of fine pink cloth worn as a shirt, but leaving the neck entirely bare; a vest of cloth with sleeves sitting easy on the arm; a tunic descending over this to the knees, opening before, and bound round with a white sash, to which is attached the sword; trousers to the knees; whilst a sort of stocking, and a close-laced half boot, complete this picturesque costume. The Georgian women equal the men in grace, and are famed all over the East. Their dress is cumbersome and overloaded with ornament, and the face painted so as entirely to injure its expression. Under its gallant prince Heraclius, Georgia rose to the dignity of a separate kingdom. This country originally included nearly the whole northern declivity of the Caucasus, extending from the Black Sea to the Caspian. It is now divided into the four provinces of Cartuel, Kaket or Kacheti, Kisik called sometimes Tomchet, and Georgian Armenia. The inhabitants consist chiefly of Christians of the Greek communion; to which are added Jews, Tartars, Armenians, and Russians. The chief rivers are the Kur and the Araxes, which fall into the Caspian. The chief, and indeed the only place of any consequence, is Tiflis, which, under the protecting policy of Russia, has rapidly grown up into a considerable mart of eastern commerce, and is on the increase. The inhabitants are not estimated at more than 320,000.

GEORGIA, one of the United States of North America, is situated between 30. 19. and 35. north latitude, and 3. 52. and 8. 47. west longitude. It is bounded on the north by Tennessee and North Carolina, on the north-east by South Carolina, on the south-east by the Atlantic, on the south by Florida, and on the west by Alabama. In length it extends 300 miles, having an average breadth of about 200 miles, and containing about 58,000 square miles. For nearly 100 miles along the sea-shore there is a broad maritime belt of level country. Along the coast there are a number of islands; whilst the numerous rivers, creeks, and inlets of the sea overflow the swamps or marshes with which they are bordered at almost every return of the tide. These swamps, however, constitute the rice plantations. Beyond the sea-marshes commences an extensive belt of pine barrens, extending from sixty to ninety miles from the sea, and closely resembling those of South Carolina. Beyond this belt the country becomes diversified with hills and mountains, and possesses a strong rich soil, called technically *mulatto soil.* This region is bounded on the west by a chain of hills called the Blue Ridge, which here swells into elevations about 1500 feet in height. An extensive track of table-land now succeeds, possessing a black soil of great fertility, in which pines and evergreens are more rare, their place being supplied by black walnut and other forest trees, which indicate a rich soil.

The principal rivers are, the Savannah, Ogeechee, Alatamaha, Satilla, Oakmulgee, Oconee, St Mary's Flint, Chatahoochee, Tallapoosa, and Coosa. Tides flow up the Savannah for twenty-five miles, and the largest vessels can approach within three miles of the city of Savannah, eighteen miles from the ocean. The Ogeechee river pursues a south-east course through the state for 200 miles. A canal from the Savannah to the Ogeechee has been finished, and it is in contemplation to extend it to the Ala-

Georgia. tamaha, which will make in all seventy-two miles. The latter river is a broad and deep stream, having numerous branches.

Amongst the mineral productions of Georgia may be mentioned copper and iron ores, the latter being found in great abundance. The gold region extends in a broad belt through this state; and it is conjectured that gold would be found much more abundantly in the high lands of Georgia and Alabama than in the eastern section of the gold region.

In front of the broad belt of salt marsh which skirts the sea-shore, there is a chain of islands of great value for their capability of yielding sea-island cotton, and as retreats, during the sickly months, for the low country planters. The soil of these islands is rich, and covered with pine, hickory, and live oak, in their natural state. The names of the principal of these are, Tybee, Assaw, Ossabaw, St Catherine's, Cumberland, Jekyl, Sapelo, and St Symon's.

The climate is similar to that of South Carolina; indeed in a variety of its features Georgia resembles that state. The low countries have their sickly season, and the planters are compelled to fly in summer to retreats amongst the high pine woods. The districts central to the rice swamps are invariably insalubrious. In some portions of Georgia the temperature approaches the tropical more than it does in any part of South Carolina, and these districts are accordingly better adapted to the cultivation of the sugarcane, the olive, and sweet orange. The hilly and western parts of the state are as healthy as any part of America. Winter may be said to commence in the middle of December, and to end in the middle of February.

The staple production of the country is cotton, of which both the black-seeded and sea-island kinds are reared. The product next in importance is rice, with which grain the swamps are sowed. Indigo and tobacco are also cultivated to some extent, but sugar and wine are only produced in small quantities. The cultivation of silk has been successfully attempted, and the quality is said to be excellent. The forests afford an abundant supply of fine timber, consisting chiefly of oak, pine, hickory, mulberry, and cedar. Melons grow in high perfection, and figs are also common. Oranges, limes, citrons, pears, peaches, and a few other fruits of mild climates, are likewise cultivated. The exports, consisting chiefly of cotton, rice, deer skins, timber, &c. amounted in 1828 to 4,981,376 dollars. The tonnage was at that period 13,959 tons.

Savannah is the commercial capital of Georgia. It is situated on the western bank of the river of the same name, at about eighteen miles from its estuary. It stands upon a low sandy plain, and contains twelve public buildings and eight churches. There are ten public squares planted with trees, amongst which the beautiful China trees are conspicuous. Savannah is a place of considerable trade, and occasionally exports annually 120,000 bales of cotton, besides large amounts of rice and tobacco. The exports of rice were, in 1826, 11,455 tierces, and of tobacco 170 hogsheads. The town is defended by two forts, and the entrance to the river is indicated by a lighthouse on Tybee Island. The population was, in 1830, 7473. Augusta is a handsome town, situated on the western bank of the Savannah, about 127 miles above Savannah. It is well laid out, and chiefly built of brick. Being midway between the upper and lower country, it constitutes a central emporium of business; no town of the same size enjoys more. There is a communication by means of steam-boats between it and Savannah. The population in 1830 amounted to 6696. Milledgeville is situated on the western bank of the Oconee, 300 miles, by the curves of the river, from the ocean. Its situation is elevated and pleasant, and it is central to a fertile and populous country. It contains several public buildings, two or three churches, and about 3000 inhabitants. Athens, which also lies on the west bank of the Oconee, is the seat of the university of Georgia. The names of the other principal towns or villages are, Waynesborough, Louisville, Georgetown, Warrenton, Dublin, Laudersville, Sparta, Eatonton, Greensburgh, Madison, Jefferson, Clarksborough, Watkinsville, Marion, Darien, Hinton, Monticello, Sunbury, and St Mary's.

The legislature of Georgia, which is called the general assembly, consists of a senate and a house of representatives. It meets on the first Monday of November. The members are chosen by the counties, each county sending one senator, and from one to four representatives, according to the amount of its population. In various parts of the state a number of negroes are employed by government in working on roads, rivers, &c. The university at Athens is a well-built edifice, furnished with a respectable library, and an assortment of philosophical apparatus. The funds amount to 136,000 dollars. According to a Gazetteer of Georgia, there are about eighty incorporated academies in this state, sixty-four of which have been brought into operation. The average number of pupils in each is forty-seven, making in all 3008. In the northern and southern sections of the state there are probably five common schools in each county, forty counties, thirty pupils each, 6000; in the middle section say seven common schools in each county, twenty-five counties, 5250; total number of pupils in the academies and common schools, 14,258. The state possesses academy and poor-school funds to a considerable amount. In 1792 an act was passed by which every county was allowed to purchase the value of L.1000 of confiscated property; in each county 1000 acres of land were granted for the support of schools, and also a fund of 250,000 dollars to be vested in stocks for the same purpose. The prevailing religious denominations of Georgia are the baptists and methodists.

The first settlement of this state was made at Savannah by General Oglethorpe in the year 1733. The native Indians of this state having been more disposed to adopt the arts and modes of civilized life than in others, the white inhabitants have gradually acquired a superiority over the lands. The greater portions of two considerable tribes, the Cherokees and Creeks, reside within the chartered limits of Georgia. Those of the former tribe in particular have made very considerable advancement in civilization. They possess good houses, live in villages, pursue agriculture, and have 1277 slaves. They have amongst them carpenters and blacksmiths, and the women spin and weave, and make butter and cheese. The number of these Indians is about 15,000, and they have increased within the last six years. Their form of government is similar to that of the country in which they live. Numerous missionary establishments have been fixed amongst them, in the schools of which, according to the Gazetteer formerly referred to, 500 children are learning the English language. Georgia is divided into seventy-eight counties, and the population in 1830 amounted to 516,504, of which number between the third and the half are slaves.

GEORGIC, a poetical composition upon the subject of husbandry, containing rules clothed in a pleasing dress, and embellished with all the beauties and elegancies of poetry. The word is formed from the Latin *georgicus*, which is merely the Greek γεωργικος, from γη, *terra*, earth, and εργαζομαι, *opero*, I work or labour, from εργον, *opus*, work.

GEPIDÆ, GEPIDES, or GEPIDI, in *Ancient Geography*, according to Procopius, were a Gothic people, or a branch of that race, some of whom, in the migration of the Goths, settled in an island at the mouth of the Vistula, which they called *Gepidos*, after their own name, which signifies lazy or slothful; whilst others established themselves in Dacia, and called their settlement there *Gepidia*.

GERA, a city, the capital of the principality of Reuss. It stands in a beautiful valley on the river Elster, and has several public buildings, 850 houses, with 9050 inhabitants. It is a place of considerable manufacturing industry in linen, woollen, and cotton goods, and in brewing and distilling. Long. 12. 58. 41. E. Lat. 50. 23. 32. N.

GERARD, Alexander, eldest son of the reverend Gilbert Gerard, minister of Chapel-Garioch, in the county of Aberdeen, was born at that place on the 22d of February 1728. He received the rudiments of his education at the parish school of Foveran, where he made rapid progress; but his father having died when he was only ten years of age, his mother soon afterwards removed with her family to Aberdeen, and young Gerard was sent to the grammar-school of that city, where he attended for two years. At the end of this period, being deemed fit for the university, he was entered as a student in Marischal College, where he also distinguished himself by assiduity and proficiency in his studies; and, after passing through the usual academical course of four years, comprehending the study of Latin, Greek, mathematics, and philosophy, he was admitted to the degree of master of arts. He then commenced the study of theology, which he prosecuted in the universities of Aberdeen and Edinburgh; and in 1748, when he had little more than completed his twentieth year, he became a licensed preacher in the church of Scotland. In 1750 he was chosen assistant to Mr David Fordyce, professor of philosophy in Marischal College; and two years afterwards, upon the death of Mr Fordyce, who had been drowned on the coast of Holland, Gerard was appointed to succeed him. At this period it was the practice in Marischal College, as it continued to be in King's College, for the same professor to carry forward a class of students, during three successive years, through all the branches of philosophy which were then taught in the college, namely, logic, ontology, pneumatics, morals, politics, and natural philosophy; and, in point of fact, Mr Gerard conducted one class through this extensive course, the mathematics and the Greek being taught by separate professors. But about the year 1754 this system, which differed but little from that of tutors in the English universities, was abandoned, and, in Marischal College, each professor was restricted to one department of science. In vindication of the new plan of academical study, Gerard wrote an able pamphlet, which was printed by appointment of the college, and appears to have satisfied every one as to the propriety of the change which had been introduced. The department assigned to Gerard, in consequence of this distribution, was that of moral philosophy and logic, the duties of which he discharged with unwearied assiduity and distinguished success. He also became a member of a literary society at Aberdeen, consisting of Doctors Blackwell, Gregory, Reid, Campbell, Beattie, and other persons less known to the world as authors, which met regularly every fortnight during the winter, when the members communicated their sentiments with the utmost freedom, and received mutual improvement from the interchange of ideas in their literary discussions. From the stimulus thus given may be said to have originated Reid's *Inquiry into the Human Mind*, Gregory's *Comparative View*, Gerard's *Essay on Genius*, Beattie's *Essay on Truth*, and Campbell's *Philosophy of Rhetoric*. In September 1759, Gerard was ordained a minister of the Church of Scotland; the following year he was appointed professor of divinity in Marischal College, and minister of the Greyfriars' church in Aberdeen; and, about the same time, he was created doctor in divinity. He continued to perform the duties attached to these offices till the year 1771, when he resigned his professorship in Marischal College, as well as his church living, and was removed to the theological chair in King's College, which he held till the period of his death, in the beginning of 1795. This event happened on his birthday, the 22d of February, when, having suffered much from a schirrous tumor, he expired without a groan, in the sixty-seventh year of his age. Dr Gerard's attainments were solid rather than brilliant; the effect of close and almost incessant study aided by a sound judgment, rather than the inspirations of strong and original genius. In all the relations of life he was alike estimable and exemplary. As a clergyman, his conduct was marked by prudence, propriety, and diligence in the discharge of his ministerial duties; as a professor, his principal aim was to avoid imposing on his pupils any favourite system of opinions, and, instead of encouraging dogmatism, the parent of intolerance, to impress them with a sense of the importance of the ministerial office, to teach them the proper manner of discharging its various duties, and to enable them, by a knowledge of the Scriptures, and an acquaintance with the principles of sound biblical criticism, to form a just and impartial judgment respecting controverted subjects. Possessing large stores of theological learning, he was not more judicious in selecting his topics than successful in his manner of treating them; and he had the merit of introducing a new, and, in many respects, better plan of theological education than that which had been previously followed. As a writer, he does not rank very high. He is clear, sensible, judicious, and well informed; almost never striking, forcible, eloquent, or original. His *Essay on Genius* is more valuable for its facts than its opinions, and seldom evinces that nice, delicate, and refined discrimination without which it is impossible for any writer, whatever his talents or judgment may otherwise be, to distinguish and render perceptible to others the various shades and gradations of genius. In domestic life Dr Gerard was amiable and exemplary; steady and disinterested in his friendships; hospitable, benevolent, and unassuming in the intercourse of society; uniting with the sobriety of the Christian pastor the good breeding of the gentleman, and the cheerfulness, affability, and ease of the agreeable companion. Dr Gerard's works are, 1. An Essay on Taste, to which the gold medal was, in 1756, adjudged by the Philosophical Society of Edinburgh; 2. Dissertations on the Genius and Evidences of Christianity, 1766; 3. An Essay on Genius, 1774; 4. Two volumes of Sermons, 1780, 1782; 5. A part of his theological course, entitled The Pastoral Care, published in 1799, by his son Dr Gilbert Gerard, who succeeded him as professor of divinity in King's College.

GERARDE, John, a surgeon in London, and the greatest botanist of his time, was many years chief gardener to Lord Burghley, who was himself a great lover of plants, and had the best collection of any nobleman in the kingdom, amongst which were a great number of exotics introduced by Gerarde. In 1597 the latter published his *Herbal*, which was printed at the expense of J. Norton, who procured from Frankfort the same blocks in wood which were used in the herbal of Tabernæmontanus. In 1663, Thomas Johnson, an apothecary, published an improved edition of Gerarde's book, which met with such approbation in the university of Oxford that they conferred upon him the degree of doctor of physic. The descriptions in the *Herbal* are plain and familiar; and both these authors have laboured more to make their readers understand the characters of the plants than to inform them that they themselves understood Greek and Latin. The *Herbal* of Gerarde is now considered only as a literary curiosity. The figures in general express very accurately the characters of the plants which they are intended to represent.

GERGONG, or Ghergong, a city of Assam, and formerly the principal town of that country, situated on the Dekhow river, one of the numerous tributary streams of the

Brahmapootra. It occupied formerly a very large space, every house being surrounded by a garden, and the rajah's palace being encompassed by a stockade of bamboos and a wet ditch; so that the city covered a space of nearly ten miles. The city, palaces, and fort are now a heap of ruins. Long. 94. 40. E. Lat. 26. 55. N.

GERMAIN-EN-LAYE, St, a city of France, in the department of the Seine and Oise, and arrondissement of Versailles, twelve miles from Paris. It is built on a slope rising from the river Seine. In the environs are some fine woods surrounding a park, in which is the royal palace, the birthplace of Louis XIV., and where our King James II. held his court after his loss of the British crown. The city contains about 12,000 inhabitants, some of whom are employed in tanneries and hosiery, and many in cultivating garden vegetables for the supply of the metropolis. Long. 2. 7. 35. E. Lat. 48. 50. 37. N.

GERMAINS, St, a borough and market-town of Cornwall, in the hundred of East Cornwall, 227 miles from London. It was at one time, from 981 to 1049, the see of a bishop, and the ancient cathedral is still used as the parish church: the ruins of the episcopal palace may also be traced near the town. Two members are returned to parliament, chosen by the inhabitants within the borough, which is of very contracted limits. There is a market on Friday, but it is thinly attended. The population amounted in 1801 to 2030, in 1811 to 2139, in 1821 to 2404, and in 1831 to 2586.

GERMAN, in matters of genealogy, signifies whole, entire, or own. *Germani, quasi eadem stirpe geniti.* Hence *brother-german* denotes a brother both by the father's and mother's side, in contradistinction to uterine brothers, who are so only by the mother's side; or brothers consanguinean, who are so by the father's side alone. *Cousins-german* are those in the first or nearest degree, being the children of brothers or sisters. Amongst the Romans we find no instance of marriage between cousins-german before the time of the Emperor Claudius, when they were very frequent. Theodosius prohibited such marriages under very severe penalties, including even fine and proscription.

GERMANIA. See Germany.

GERMANICUS, the son of Drusus and Antonia the younger, born 16 B. C. and died 19 A. D., who seems to have inherited all the virtues of his father, and to have been distinguished, in a profligate and selfish age, for strictly honourable conduct, and a kind regard to the feelings of others. He was a particular favourite of Augustus, who caused him to be adopted (4 A. D.) into the family of his uncle Tiberius, and gave him the command of eight legions on the banks of the Rhine (7 A. D.). Here he remained till the death of Augustus (14 A. D.), regulating the affairs of Gaul, and keeping in check the restless and warlike Germans beyond the Rhine. He was engaged in collecting the revenue in Gaul when the news of the emperor's demise reached him, and he does not appear to have hesitated a moment as to the course which his duty called on him to pursue. Though urged by his personal friends, and not ignorant of the strong party which the popular conduct of his family had secured to him, he refused to contest the crown with his uncle Tiberius. On the contrary, he hurried to the armies in Germany to employ his influence in inducing them to submit to the authority of Tiberius, and upon his arrival found that the armies of both the Upper and Lower Rhine had refused to take the oath of allegiance, and wished to proclaim himself emperor. It required all his firmness and prudence to extricate himself from the difficulties in which he found himself involved, and he only succeeded in quelling the sedition by forging an imperial rescript, granting them all that they demanded. The appearance of deputies from the senate caused the sedition again to break out; but he contrived to induce the less violent part of the soldiers to seize the ringleaders and put them to death. (Tacit. *Ann.* i. 31–35.) He then led his troops against the Marsi and Catti, to give them an opportunity of atoning for their conduct, and laid waste the country inhabited by these tribes. The next year Arminius, who possessed great influence with his countrymen, induced them to revolt. The Cherusci, one of the most powerful nations of Germany, and all the surrounding tribes, prepared to make an incursion into the Roman territory; but Germanicus, becoming acquainted with their intentions, anticipated them in their movements, and boldly penetrated into their country. Defeating the Bructeri near the spot where Verus and his legions had fallen, he pursued Arminius; but the battle which he fought was doubtful. Next year he determined to save his army from the risks and fatigues of a march through a thickly-wooded and difficult country, by building a fleet and conducting it along the coast. He was successful in this proceeding, and landed his army at the mouth of the river Amisia, *Ems.* He defeated the united forces of the Germans in two battles; but as he was returning to the Rhine he was overtaken by a tempest, and many of his vessels were lost. Tiberius, suspicious of his intentions, and jealous of his popularity, took this opportunity of withdrawing him from the scene of his glory. On his return to Rome he enjoyed the honour of a triumph for all the victories he had gained over the Germans. (Tacit. *Ann.* i. 51–71; ii. 6–26.)

Germanicus was too formidable a subject and too virtuous a character not to excite unmingled fear in the mind of the suspicious Tiberius; and as the tyrant did not dare to cut him off in presence of the Roman people, he sent him into honourable banishment, by giving him the command of the province of Asia. Thither the emperor had also sent Piso, who was devoted to his interests, and the uncompromising enemy of Germanicus, a person, in short, who would stop at nothing to rid himself of his opponent. At Antioch Germanicus was taken ill, and died after a short illness, the innocent victim of Piso and his master Tiberius. He was deeply regretted by the Roman people, who regarded him as likely to bring back the halcyon days of the Augustan age. It will readily be imagined that he was a patron of literature and the sciences; and he was himself an author, having translated the Phenomena of Aratus, and written epigrams, several of which have been preserved. They have been published in a work entitled *Carmina Familiæ Cæsareæ*, Coburg, 1715. His life has been written by Beaufort, Leyden, 1741.

GERMANO, St, a city of the province Terra di Lavoro, in the kingdom of Naples. It stands at the foot of the mountain on which the magnificent convent of Monte Cassino is built. It contains 4839 inhabitants. It is remarkable as the spot where the battle was fought, in 1815, in which Nugent scattered and destroyed the army of Murat.

GERMANTOWN, a post-town of North America, in the state of Pennsylvania, and county of Philadelphia. It is pleasantly situated about seven miles north of Philadelphia, the capital. Most of the houses are built in one continuous line of street, which is about two miles in length. This place possesses considerable manufactures, and a population of about 5000.

GERMANY.

This name was given by the Romans to a country inhabited by various small tribes, under different names, and probably of different origins, but who were so nearly similar in manners, language, and religion, as to lead those further advanced in civilization to confound them all under one common denomination. Under that denomination was comprehended not only the country now called Germany, but Denmark, Norway, Sweden, Finland, Livonia, and Prussia. The name is said to be derived from two words, *Ghar man* or *Wehr-man*, meaning war-man or warrior, which is also the signification of two other words, *Ale man*, of the same import. They were by themselves called Teutones, from one of their national divinities, Teut, or, as is sometimes said, Thuiskon, who seems to have been the general object of veneration, and from whom the name is derived which is now assumed by all the people who call their country Teutchland or Deutchland.

The Rhine on the west, and the Vistula on the east, were considered, at the most remote periods, as the boundaries of Germany; whilst on the north it extended along the ocean and the Baltic Sea, and on the south was terminated by the river Danube. But such boundaries were by no means definite; for many German tribes inhabited the southern banks of the Rhine as far as the Scheldt. Between the Rhine and the Moselle were the Ubii; and higher up, but beyond the latter river, were the Treviri, and then the Triboci, the Neimetes, and the Vangiones. The Mediomatrici were planted along the Moselle, near the site of the present city of Metz; and above them, on the Rhine, in the present Swiss canton of Basil, were the Raurici or Rauraci. The ancient nations of Vindelicia were settled between the sources of the Rhine and of the Danube. Noricum was inhabited by several tribes between the rivers Drave and Danube, and comprehended the provinces now known by the names of Austria, Styria, Carinthia, Tyrol, and Bavaria. Beyond the Danube, to the westward of the Marcomanni, the country was occupied by the Hermunduri, and extended to the north along the Hercynian Mountains to the river Sala. A nation beyond the Hercynian Mountains, known then as the Boiohemum, and in modern times as Bohemia, were in contact with the Quadii, whose territory, now called Moravia, touched, on its southern part, the Danube. These two tribes, with the Marcomanni, and some smaller clans, were comprehended under the general name of Suevi, a people who at a subsequent period forced their way into Spain, and established themselves in that peninsula as a warlike and independent nation. The Suevi were a powerful nation, who extended themselves along the Hercynian Forest, through which they penetrated, and occupied a tract of land extending from the Vistula to the Elbe. Among their possessions were the divisions which subsequently obtained the names of Saxony, Brandenburg, Lusatia, and Silesia. One subdivision of them, called the Semnones, grew sufficiently powerful to seize some of the richest provinces of Gaul; whilst another, the Æstii, possessed the borders of the Baltic Sea, whence they drew much amber, of which they made use in traffic with the surrounding tribes. These last, according to Tacitus, were worshippers of the mother of the gods, and relied on her for protection. They are said to have been more industrious than the rest of the Germans in the cultivation of their lands, and at a very early period produced corn. Their amber was reported to have been obtained by diving in the rivers and the sea. This substance was then highly estimated; and at a subsequent period, in the reign of Nero, a Roman knight is stated to have purchased for that emperor, of the Æstii, at one time thirteen thousand pounds weight, amongst which was a single piece weighing thirteen pounds. At a still later period, a letter is found in Cassiodorus, in which Theodoric, king of the Goths, gives thanks to the Æstii for a present of amber, and in return assures them of his friendship and protection.

In the interior of Germany, the Cimbri and the Saxons were possessed of the country north of the Elbe; whilst on the south side of that stream the Chauci were the masters of the district through which the Weser flows, and were in contact with the two smaller tribes of the Cherusci and Chamavi. The Frisii were distinguished as the Upper and the Lower, and were separated from the Chauci by the river Ems, and from each other by a branch of the Rhine; whilst beyond the Yssel were some migratory tribes, the Bruckteri and the Marsi. The Uspetes were established on the river Luppia, now the Lippe; and beyond that stream were the Usipetes, who were celebrated for changing their residence, and were thence to be found in other districts. The Teucteri were settled on the Rhine, in the country of the Menopii; and next to them the Jubones, near the modern Juliers. The Catti or Cotti inhabited parts of Hesse and Thuringia, extending from the Hartz Mountains to the Rhine and the Weser. Their southern neighbours were the Sedusi, bordering on Suabia, where they came in contact with the Marcomanni, who have been already mentioned.

Such are the best accounts which can be collected from Cæsar, Tacitus, and Ptolemy, respecting the localities of the various tribes who inhabited Germany before the period of the intercourse between them and the Romans. It has been justly remarked, that whilst modern nations are fixed and permanent societies, connected amongst themselves by laws and government, and bound to their native soil by arts and agriculture, the German tribes were only voluntary and fluctuating associations of soldiers, almost of savages; and the same territory often changed its inhabitants in the course of conquest or of emigration. A victorious state often communicated its own name to a vanquished people. Sometimes crowds of volunteers flocked from all parts to the standard of a victorious leader; his camp became their country, and some event soon gave a new but general name to the mixed community. Thus the distinctions of ferocious invaders were perpetually varied by themselves, and naturally confounded the astonished subjects of the Roman empire.

It is probable that the accounts of the numbers of the German people, as transmitted by early writers, are grossly exaggerated. In great and civilized states, millions of subjects pursue their peaceful avocations in silence and obscurity; but in a state of rude republicanism, or of civil commotions, almost every member of the community is called into active exertion; and thus, with their irregular divisions, their restless motions, their profusion of kings and warriors, and numerous contests, they present to our minds an appearance of numbers very far beyond the reality, which is still further strengthened by the most splendid appellations being frequently and repeatedly applied to inconsiderable objects. When the Romans first became acquainted with Germany, about the year 640 from the building of their capital, or more than 100 years before the commencement of the Christian era, the natives had advanced but a few steps from the savage state. Even in the subsequent age, as Tacitus affirms, they were so ignorant of the use of letters as to be unable to transmit from one generation to another any annals of their country, or any knowledge of the agreeable or useful arts of life. In an extent very far surpassing modern Germany, Ptolemy speaks of ninety towns or cities; whilst Tacitus asserts, as a well-known fact, that in his time they had no cities, and that they affected to despise the buildings constructed by Roman industry, as places of confinement rather than of security. Their dwellings were not even contiguous, nor formed into villages, but each of these barbarians fixed his independent dwelling on any spot which a plain, a wood, or a stream of good water, invited him to settle on; and in constructing his hut, neither stone, brick, nor tiles were employed. Built of timber, they were very low, and covered with straw, having a hole to allow of the emission of the smoke.

The clothing was of the simplest kind, notwithstanding the inclemency of the climate in a territory covered with woods, and not ameliorated by cultivation. In the more northern parts scanty garments of furs were used; and in the south some coarse linen, spun and woven by the females. Their food consisted chiefly of wild animals, or of the flesh of their large herds of cows and of horses, which were nearly in the state of their original wildness. A small quantity of corn was the only produce of the soil; the use of gardens, orchards, and artificial meadows, was unknown; nor could any great improvement in agriculture have existed, where a new division of the land took place annually, and a great part lay waste and without any tillage. The Germans seem to have learned the process of brewing or of distillation, as they made intoxicating liquors from wheat and barley, in the use or abuse of which they indulged to the greatest excess in social meetings and public assemblies. Drinking and gambling were their highest gratifications. They gloried in passing whole days and nights at the table; and the blood of guests, often of friends and relations, stained their drunken assemblies. The desperate gamester often staked his person and his liberty on the cast of a dice, and then patiently submitted to the decision, and was sold into slavery by his more fortunate competitor.

Notwithstanding the grossness of manners amongst the German tribes, the females were held in high estimation; and whilst the men were brave, the women were chaste. Polygamy was not in use excepting amongst the princes; and amongst them only for the sake of multiplying their alliances. Divorces were prohibited by manners rather than by laws. Adulteries were punished as rare and inexpiable crimes; nor was seduction justified by example and fashion. The unpolished wives of the Germans partook of few of those gratifications which tend to inflame the passions, and their fidelity was in some measure secured by the exposure to which they were subject in the open huts, and by poverty, solitude, and the painful cares of domestic occupation. Besides these restraints, the Germans treated their women with esteem and confidence, consulted them on every occasion of importance, and fondly believed that in their breasts resided a sanctity and wisdom more than human. Some of these interpreters of fate, such as Velleda in the Batavian war, governed, in the name of the deity, the fiercest nations of Germany. The rest of the sex were respected as the free and equal companions of soldiers, associated even by the ceremony of marriage to a life of toil, of danger, and of glory. In their great invasions, the camp of the barbarians was filled with a multitude of women, who remained firm and undaunted amidst the sound of arms, the various forms of destruction, and the honourable wounds of their sons and husbands. Fainting armies of Germans have more than once been driven back upon the enemy by the generous despair of the women, who dreaded death much less than servitude. If the day was irrecoverably lost, they well knew how to deliver themselves and their children, with their own hands, from an insulting victor. Heroines of such a description may claim admiration, but they can scarcely inspire the passion of love. They who attempt to imitate the sterner virtues of man must lose the attractive softness of their own sex, which is their principal charm. Conscious pride taught the German matrons to suppress every tender emotion which stood in competition with honour; and the first honour of the sex has ever been that of chastity.

The Germans were a warlike people, notwithstanding which their government was a species of democracy, although a few of the tribes on the shores of the Baltic acknowledged the authority of kings; but such kings owed their power as frequently to their valour or their eloquence as to their descent; and with all of them the power was tempered by the prevalence of popular assemblies. The assembly of the warriors of the tribe was convened at stated seasons, or on sudden emergencies. When a youth had attained the age of manhood, he was introduced into the general council of his countrymen, solemnly invested with a shield and a spear, and adopted as an equal and worthy member of the commonwealth. In such assemblies, the trial of public offences, the election of magistrates, and the great affairs of peace or war, were determined by independent votes. Sometimes these important questions were previously considered and prepared in a committee or select council of the principal chieftains. The magistrates might deliberate and persuade, but the people only could resolve and execute; and hence the resolutions were for the most part hasty and violent. They too often turned away with indignant contempt from the remonstrances of justice and policy, and signified by a hollow murmur their dislike of such timid councils. But when a popular orator proposed to vindicate the meanest citizen from either foreign or domestic injury, or called upon his countrymen to follow some enterprise of danger and of glory, the applause of the assembly was displayed by a loud clashing of shields and spears; for the Germans always assembled in arms, and it was to be dreaded lest an irregular multitude, inflamed by faction and strong liquors, should use their arms to enforce as well as to declare their furious resolutions.

A general of the tribe was elected on occasions of danger; and if the danger was pressing and extensive, several tribes concurred in the choice of the same general. The bravest warrior was named to lead his countrymen into the field by his example rather than by his commands; but this power, however limited, was still invidious. It expired with the war, and in time of peace the German tribes acknowledged not any supreme chief. Princes were, however, appointed in the general assembly, to administer justice, or rather to compose differences, in their respective districts. In the choice of these magistrates, as much regard was shown to birth as to merit. To each was assigned by the public a guard and a council of a hundred persons; and the first of the princes appears to have enjoyed a pre-eminence of rank and honour which sometimes tempted the Romans to compliment them with the regal title.

The comparative view of the powers of the magistrates, in two remarkable instances, is alone sufficient to represent the whole system of German manners. The disposal of the landed property within their district was absolutely vested in their hands, and they distributed it every year according to a new division. At the same time they were not authorized to punish with death, to imprison, or even to strike, a private citizen.

The Germans respected only those duties which they imposed on themselves. The most obscure soldier resisted with disdain the authority of the magistrates. "The noblest youths," says Tacitus, "blushed not to be numbered amongst the faithful companions of some renowned chief, to whom they devoted their arms and service. A noble emulation prevailed among the companions to obtain the first place in the esteem of their chief, among the chiefs to acquire the greatest number of valiant companions. The glory of such heroes diffused itself beyond the narrow limits of their own tribe. Presents and embassies solicited their friendship, and the fame of their arms often ensured victory to the party they espoused. In the hour of danger it was shameful for the chief to be surpassed in valour by his companions, and shameful for the companions not to equal the valour of their chief. To survive his fall in battle was indelible infamy. The chiefs combated for victory, the companions for the chief. The noblest warriors, whenever their native country was sunk in the laziness of peace, maintained their numerous bands in some distant scene of action, to exercise their restless spirit, and to acquire renown by voluntary dangers. Gifts worthy of soldiers, the warlike steed, the bloody and ever-victorious lance, were the rewards which the companions claimed from the liberality of their chief. The rude plenty of his hospitable board was the only pay which he could bestow, or they would accept. War, rapine, and the freewill offerings of his friends, supplied the materials of this munificence." This institution, however it might accidentally weaken the several republics, invigorated the general character of the Germans, and even ripened amongst them all the virtues of which barbarians are susceptible; the faith, valour, and hospitality so conspicuous long afterwards in the ages of chivalry.

The religion of the Germans was as gross as that of other nations in the same low stage of civilization. They adored the sun and the moon, the fire and the earth, together with those imaginary deities who were supposed to preside over the most important occupations of human life. They were persuaded that, by some ridiculous arts of divination, they could discover the will of the superior beings, and that human sacrifices were the most precious and acceptable offering to their altars. They seem to have adopted no images as visible objects of worship, nor to have constructed any edifices for the celebration of religious rites. Their only temples were dark and ancient groves, consecrated by the reverence of successive generations. Their secret gloom, the imagined residence of an invisible power, by presenting no distinct object of fear or worship, impressed the mind with a still deeper sense of religious horror; and the priests, rude and illiterate as they were, had been taught by experience the use of every artifice which could preserve and fortify impressions so well suited to promote their own interest.

The German priests had assumed a jurisdiction even in temporal concerns which the magistrate could not venture to exercise; and the haughty warrior submitted to the lash of correction, when it was inflicted, not by any human power, but by the immediate order of the god of war. Thus the defects of civil policy were sometimes supplied by the interposition of ecclesiastical authority. The latter was constantly exerted to maintain silence and decency in the popular assemblies, and was sometimes extended to a more enlarged concern for the national welfare. A solemn procession was occasionally celebrated in what are now the countries of Mecklenburg and Pomerania. The unknown symbol of the earth, covered with a thick veil, was placed on a carriage drawn by cows; and in this manner the goddess, whose common residence was in the island of Rugen, visited several adjacent tribes of her worshippers. During her progress the sound of war was hushed, quarrels were suspended, arms laid aside, and the restless Germans had an opportunity of tasting the blessings of peace and of harmony. The truce of God, so often and so ineffectually proclaimed by the clergy of the eleventh century, was an obvious imitation or continuation of this ancient custom.

But the influence of religion was far more powerful to inflame than to moderate the fierce passions of the Germans. The consecrated standards, long preserved in the groves of superstition, were placed in the front of the battle; and the hostile army was devoted with dire execrations to the gods of war and of thunder. With the Germans cowardice was the most unpardonable of sins. A brave man was the worthy favourite of the martial deities. He who had lost his shield was banished alike from the civil and the religious assemblies of his countrymen. Some of the northern tribes seem to have embraced the doctrine of transmigration; others imagined a gross paradise of immortal drunkenness. All agreed that a life spent in arms, and a glorious death in battle, were the best preparations for a happy futurity, either in this or another world.

That singular order of men, the bards, have attracted to them the attention of all who have attempted to investigate the antiquities of the Celts, the Scandinavians, and the Germans. It is not easy, however, to calculate the enthusiasm of arms and glory which they kindled in the breasts of their audience. It was in the hour of battle, or in the feast of victory, that the bards celebrated the glory of the heroes of ancient days, the ancestors of those warlike chieftains who listened with transport to their artless but animated strains. The view of arms and of danger heightened the effect of the military song; and the passions which it tended to excite, the desire of fame, and the contempt of death, were the habitual sentiments of a German mind.

Such is the description of the manners, characters, and propensities of the ancient Germans, as delineated by Tacitus, and by which, in spite of their climate, their want of learning and the arts, and the absence of fixed laws, they were formed into a people of military heroes, and enabled to carry on formidable hostilities, during more than two centuries, with the mighty power of the Romans.

The early history of the Germans, like that of all nations who had no written records, is involved in much obscurity. The first knowledge of their transactions was that of the invasion of the country by the Gauls, commanded by Segovesus, king of the Celtæ; whilst his brother Bellovesus marched with another army into Italy; both of which divisions are said to have been directed by the flight of birds. Segovesus crossed the Rhine, and gained a settlement near the Hercynian Forest. The Germans, however, soon acted on the offensive, and expelled the Gauls, and, by the assistance of the Belgæ, one of their most warlike tribes, gained possession of some territory to the west of the Rhine, where they were enabled to fix and maintain themselves so firmly as never to be driven out, and whence they extended themselves to the sea-coasts of Britain, and even drove its inhabitants into the interior. The Germans and the Gauls, thus brought into contact with each other, continued to hold vacillating intercourse, sometimes at war, at other times in alliance in opposition to the power of the conquering and disciplined Romans. The Germans, under the name of Cimbri, then invaded the territory of Rome, and spread such terror, that Marius, by a deviation from the law, was appointed consul to command an army against them. After various marches during some years, in 102 before Christ, Marius, with an army of 52,000 men, attacked the barbarians on the banks of the Rhone, and, though they are said to have mustered 300,000 foot and 15,000 horse, completely defeated them, with a loss of 150,000 killed and 60,000 prisoners. Many, preferring death to slavery, underwent military execution; and a few were scattered over Gaul, or crossed the Danube, and so escaped to their own country.

After Julius Cæsar had completed the subjugation of Gaul, and extended his conquest to the Rhine, he first became acquainted with the German name. Ariovistus, the leader of a tribe that dwelt to the south of the Danube, attempted to fix his establishment in Gaul, but was defeated by Cæsar, and, with the loss of 80,000 men, was driven across the Rhine, though two tribes of his followers remained on the west side of that river; and the fugitives who returned augmented the numbers of the German tribe of the Marcomanni. Cæsar built a bridge over the Rhine, and twice passed that river at the head of his army, not with the view of permanent conquest, but to secure his province of Gaul against the attacks of the barbarians; and he also took many of the Germans into his pay, first in the war with the Gauls, and afterwards in the civil contest with Pompey. The civil wars, which occupied first Cæsar and Pompey, and afterwards Mark Antony and Brutus and Cassius, left the Germans opportunities to attempt incursions. The confederation of the Segambri passed the Rhine, and having repelled the attack of Agrippa, settled themselves on the western side of that river; but a few years afterwards they were defeated by Lollius the legate of Augustus, when, 14 years before Christ, Drusus, the son-in-law of the emperor, constructed several fortresses along that river, to prevent the incursions of the Germans. He proceeded with success, and penetrated as far as the Elbe. He died in the year 8 before Christ, and was succeeded by Tiberius, who during his command not only sustained the power which Drusus had acquired, but extended it towards the north; and, by intrigues among the natives, as much as by his force, induced many of the tribes to solicit peace, and excited others to enter into the military service of Rome. The body-guard of Augustus was composed of German volunteers, amongst whom was the distinguished noble whose name has descended to posterity, being sometimes called Hermanus, and at others Arminius, who received the privileges of a Roman citizen and the dignity of a Roman knight. He was the son of Sigmer, a prince of the Cherusci, and had been educated in Rome, and early appointed an officer in the army of Augustus, but is said never to have lost the relish for the customs of his ancestors, nor his zeal for the independence of his country; and during the course of his instruction in arts and in arms he warmly cherished the hope of adapting these instructions to the purpose of freeing his country from the Roman yoke. He felt a confidence that all the discipline of the Roman armies would be unable in a fair field to resist the raw bravery of his unpolished countrymen.

The best legions of Rome were intrusted to the command of Quintilius Varus, with the superintendence of the territories on the right bank of the Rhine, which had been added by Drusus to the Roman dominion. He was confident in the power of his military superiority, and thought, in addition to that, to secure obedience by changing the customs and principles of the Germans, and thus converting them into useful subjects. For this purpose he took with him a great number of civil officers, lawyers, and men of letters, to introduce the new order of things. These measures roused the jealousy of a people enamoured of their freedom, and disseminated the seeds of insurrection amongst all the tribes situated between the Rhine and the Elbe. Arminius availed himself of this spirit to form alliances in opposition to Varus, amongst all the military leaders of the districts. It happened most opportunely for the purpose of Arminius, that, in the year 9 A. D., a general revolt broke out on the Roman frontiers of Dalmatia and Pannonia. It is doubtful if this was connected with the plans of Arminius, but it helped to strengthen the confederacy which had been entered into by those tribes which were in possession of the country bounded by the Rhine, the Saale, and the Elbe. This confederacy was not broken up by the treason of one of the chiefs, Segestes, the leader of the Catti, who communicated to the Roman commander the plan and the detail of the intended insurrection, which was received by Varus with the contempt which reliance upon the numbers and discipline of his troops had inspired. Arminius redoubled his assiduities to remove suspicion, if any existed, of his fidelity to the Roman cause, and succeeded, by pointing the attention of Varus to some irruptions which, at the instigation of the confederacy, had broken out on the banks of the Weser. These small but concerted disturbances were intended to inveigle the Roman commander to advance into the interior of the country; and the leaders of the German troops in the pay of Rome, who were involved in the confederacy with Arminius, by the display of unbounded zeal and obedience, agreed in urging the Roman commander not to wait for further displays of resistance, but to advance with his three legions and the auxiliaries, and to extinguish the rebellion in its focal point. In vain did Segestes repeat his warnings. Nothing could shake the confidence of Varus in Arminius, and the confederates and the Romans plunged deeper and deeper into the heart of the country, where the snares had been laid for their destruction. Near the sources of the river Lippe, in the country of the Bructeri, after a long and wearisome march through woods and morasses, the Romans saw themselves enclosed on every side in a hollow surrounded by hills whose summits were all occupied by the natives. At this moment intelligence arrived that Arminius with the rear division, consisting of stipendaries, which he commanded, had declared against the Romans, and had been the moving spring of the whole operations. Varus saw clearly destruction before him; for though discipline and courage might prolong the contest, it could inspire no hopes of a successful issue.

Three days of suffering and ineffectual hostilities compelled the Romans to submit. Varus chose death rather than disgrace. Three Roman eagles were taken; and a limit was thus set to the advances of the Romans towards the north, which they were never afterwards enabled to pass. The Germans disgraced their victory by useless cruelties. Some of the men of letters and artists who were taken had their hands cut off, and others were blinded. The site of this memorable event cannot be clearly ascertained by any records, but it is generally placed by the antiquarians of Germany near the sources of the rivers Lippe and Ems, not far from where now stands the small city of Detmold. The event occurred in the ninth year of our era.

When Arminius had thus restored the ancient freedom to his country, he destroyed the fortresses which the Romans had constructed on the Rhine, the Elbe, and the Weser, and exerted himself to rouse the military spirit of the Germans, and taught them to rely on that spirit rather than on the strongest fortifications. A civil war soon broke out amongst the natives themselves, and the party opposed to Arminius was headed by Segestes. That prince applied to the Romans for assistance, and was aided by their general Germanicus, when he was surrounded by the troops of Arminius. His deliverance was effected with but little loss on either side; but the wife of Arminius was taken prisoner by Segestes, and on being carried before the Roman general, maintained a spirit and dignity which is highly applauded by Tacitus. The treachery of Segestes animated the exertions of Arminius, and he was offered assistance by his uncle Inguiomar, a leader of a tribe, and celebrated as a warrior. Arminius attempted also to gain to his party his brother Flavius, who like himself had been educated in Italy, but who resolutely maintained his fidelity to the Roman power. Arminius desired a meeting with Flavius, and they saw and conversed with each other across the river Weser. The expostulations and the inducements of Arminius were ineffectual; the brothers became exasperated against each other, and would have proceeded to feats of arms if they had not been separated by the stream, and at length been borne away from the scene by their respective partisans.

Germanicus the Roman commander once more attacked the army of Arminius, and gained a splendid but useless victory on the plain of Idistavius, on the banks of the Weser; but having excited the suspicious jealousy of the Emperor Tiberius, the necessary succours were withheld, and Arminius was soon enabled again to make head against the Romans, and caused them to suspend their attempts on the freedom of Germany. This temporary tranquillity, however, gave rise to an intestine war.

Marobodus, a leader of the Marcomanni, but who had been educated in the court of Augustus, was enabled by his address and his power to unite many tribes of the Suevi in a confederacy with his own nation, which collectively assumed the name of the Marcomanni. At the head of this powerful league he attacked and conquered the nation of the Boii, seated in the south of Bohemia and a part of Franconia, and founded a formidable state, which extended over the Hermundurins, the Quadi, the Longobards, and the Semnones, and could bring into the field 70,000 warriors. Augustus had given orders to Tiberius to suppress with twelve legions the power of Marobodus, but a general insurrection of the Dalmatian tribes compelled him to conclude a peace which secured to him no benefit. The subsequent disasters of the Romans in Western Germany suspended all attacks on the Marcomanni, who continued to excite insurrections in the south of Germany.

Two great powers were thus formed, the Marcomanni and the Cherusci, the one under Marobodus and the other under Arminius. Between these, dissensions speedily arose. On one side the Longobards and the Semnones, wearied by the oppressions of Marobodus, deserted his party and united with the Cherusci; and on the other side Inguiomer, the uncle of Arminius, from jealousy of his nephew, was induced to pass from his party to that of the Marcomanni. After a war between these two confederations, which was carried on with all that systematic regularity which the two commanders had learned in the Roman legions, the Cherusci remained conquerors. Tiberius, instead of giving that aid to Marobodus which he eagerly asked, left him exposed during two years to the attacks of Catualda the Goth, who compelled him to abandon his territory and seek refuge amongst the Romans; and Catualda was soon exposed to the same fate by the hostilities of the Hermundurins, who had obtained the lead among the confederates which were headed by Arminius.

The death of Arminius occurred in the year 21 A. D., at the age of thirty-seven years, during the twelve last of which he had gloriously and happily conducted the affairs of his country with the applause of his followers, to whom, after his death, he continued an object of the highest veneration. He was indeed suspected of designs to introduce royalty and to assume the kingly dignity, but it is now impossible to confirm or refute the charge which has been brought against his memory.

After the death of their leader, the Cherusci, owing to internal disputes, gradually lost the rank they had held, and at length allowed the Romans to nominate a king of their country, who assumed the name of Italicus, and was the last branch of the family of Arminius. Under him they quarrelled with their allies the Longobards, and soon sunk down into an insignificant tribe, inhabiting the district to the south of the Hartz Mountains. About the same time, in the west of Germany, the Catti raised themselves to a state of some consideration, and, whilst the Romans were occupied in suppressing an insurrection of the Frisii, seized the fortresses constructed on the Rhine. They were assailed by Galba, and induced to cede the territory included between the Lahn, the Maine, and the Rhine, to the Romans, who parcelled it out among the most meritorious of their warriors. In the year 58 the Catti and the Hermunduri contended for the salt springs on the river Saale in Franconia. The numerous followers of Marobodus and of Catualda had established themselves about the same time on the Danube, between the rivers Gran and Morava, and there, under Vannius, whom they had received as a king from the Romans, founded a new kingdom, which was soon felt to be oppressive to the people. Although Vannius had found allies in the Sarmatian Jaziges, yet he could not resist the confederacy formed against him by the Hermunduri, Lygerii, and the Western Quadi, but fled from his kingdom and took refuge with the Romans, when he was succeeded by his nephew Sido, who had performed some important services for the Emperor Vespasian. In the west the Batavians, by an obstinate struggle, shook the Roman power, which was only retained by extraordinary exertions. About this period began the war which finally terminated in the downfall of Rome. The Suevi were attacked by the Lygerii, and applied for aid to Domitian, who sent them a hundred horse soldiers, the smallness of which number was deemed an affront, and induced them to form a confederacy with the Jaziges, which threatened Dacia and Pannonia. Domitian was defeated, but Trajan proved more successful; but afterwards war broke out more fiercely under Antoninus Philosophus. The barbarians disquieted the empire on two sides without cessation. On one side small but numerous hordes of the Goths arrived in Dacia to establish themselves by force of arms; but these were removed by having a still better country pointed out to them in a southern direction. But the more terrific hostilities were those carried on by the Marcomanni, who had combined with the Hermunduri and the Quadi. Marcus Aurelius contended with them during his whole life; and Commodus purchased a peace with them in 180 A. D. At the same time the Catti laid waste Rhætia and Gaul, and the Cherusci drove the Longobards back on the Elbe, and advanced themselves under the name of Franks. About the year 220 A. D. new tribes of Germans assailed the falling empire. The Visigoths, the Gepides, and Herulians, attacked the Romans in Dacia; whilst about the same time a new race called the Alemanni, a mixed tribe, of Sclavonic origin, made their appearance in Southern Germany, in opposition to whom was constructed the celebrated *Vallum Romanorum*, the traces of which are still visible from Jaxthausen to Ohringen. The power of Rome gradually sunk, partly from the constant and increasing hostilities of the Germans and other barbarous tribes, and partly from internal dissensions. As that empire was weakened, the Franks advanced to Spain, and under Probus conquered also the Batavian peninsula. Thus the Franks and Alemanns remained the most powerful of the German nation. The former of these lost the Batavian territory to the Saxons, and the latter were humbled before the Romans in the last victory obtained by that mighty people. At the beginning of the fifth century the barbarians assailed the empire on every side. The Vandals, Suevi, and Alani became masters of Gaul and Spain. They were followed by the successful Burgundians and the Western Goths; to the Burgundians succeeded the Franks, to the Western Goths succeeded the Eastern Goths, and to them the Lombards. Then began that stream of emigration which poured from the north to the south, and, as a conquering power, became the founders of the subsequent European kingdoms. A new change was given to the face of Europe by those vast emigrations of people, mostly Germans, though some came from countries farther eastward than Germany, which gradually overspread and subdued the west, introduced new forms of society, and framed languages, which, with but little variation, have continued till the present time. The new states, formed out of what had previously been portions of the Roman empire, though often at war with each other, and differing in smaller matters, chiefly arising from difference of soil and climate, were united in one similar system of policy and domestic government, and had those common habits strengthened by the providential introduction of the Christian religion, to which, though varying in some points of faith, they all in process of time professed adherence. We have here space only for a slight sketch of the history of those emigrations the beneficial effects of which we now enjoy, and to which, during a period of more than a thousand years, Europe has been indebted for the great advancement in the arts and the policy of civilization which has raised it above the other portions of the habitable globe.

These emigrations, which thus revolutionized Europe, began from the Frozen Ocean, extended themselves to the Atlantic Sea, and stretched over a portion of Northern Africa. They continued from the year 375, when the Huns first broke into Europe, till 568, when the Lombards had completed their conquest of the Roman empire. The causes of these excursions of whole tribes were various, arising in some cases from excessive population, in others from the pressure of more remote tribes, and in all from the charms of the beautiful and well-cultivated provinces which the Romans had gradually added to their dominions. At a more early period single tribes in small parties had changed their domicils, and thereby prepared the way for the greater emigrations. The constant conquests of the too extended empire began in the middle of the third century to make it totter under its own weight. Some powerful emperors, indeed, especially Constantine and Theodosius, suspended its fall; but others, under the pressure of circumstances, and from short-sighted policy, had taken parties of the barbarians into their pay, and, as a reward for their military services, had granted them lands to establish themselves on, on the frontiers of the empire. In this way settlements were granted to the Franks in Belgian Gaul, and to the Alani, the Vandals, and the Goths, in Dacia, Pannonia, and Thrace.

Many individuals of skill and courage were appointed to offices of high power and trust, and two of them, Ruffin and Stilicho, to the command of armies. The consequence of this was, that as they improved in education, they became fully acquainted with the weakness of the Roman government, and accustomed themselves to consider it as a prey, on which in due time they might seize.

The first movement towards the emigrations was given from the farthest part of Northern Asia, where a wild and warlike tribe, probably of Mongul or Kalmuck origin, were settled on the confines of China. These, expelled from their own settlements about the end of the first century, extended themselves towards the west, and drove the Alani, a tribe from Caucasus, out of Asiatic Sarmatia, and also dislodged the Western Goths, who were settled in ancient Dacia, and in the district between the Dniester, the Danube, and the Vistula. A portion of the Alani, after long wanderings, arrived on the Danube in what is now Hungary; connected themselves there with the Vandals, an original north German colony, who had been planted there about one hundred years, and, together, pressed forward into Germany, where they further strengthened themselves by a union with the Suevi, another German tribe which had been settled on the Upper Danube. These three populations, thus united, pressed forward to the Rhine, passed that river into Gaul, captured Mayence, Strasburg, and other flourishing cities, and devastated the whole country.

After these united people had in a few years spread desolation over a great part of Gaul, they pressed on towards the Pyrenees, and entered Spain. They subdued nearly the whole of that country about the year 411, divided it by lot amongst themselves, and left a very small portion of it only in the possession of the Roman garrisons. They however retained their former discipline and courage, and formed an alliance with some of the Western Goths who had penetrated into Spain, and attacked the conquerors. The Alani, who had founded a kingdom in Lusitania, now Portugal, were completely overcome in 418; and the remnant of them, after their defeat, received protection from the Vandals; and hence from that time their name is no more to be found. They carried on the war with the Romans, and thereby gained the ascendency over them, when, in 427, they formed the resolution to pass over into Africa. The kingdom founded there by Genseric, after maintaining itself a hundred and five years, was at last subdued by Belisarius, the general of the Greek emperor Justinian. The Suevi, who after the departure of the Vandals remained in Spain, extended and maintained their power till they were defeated and scattered by the Western Goths in 584. The Huns, with whom these movements had originated, established themselves in 377 in Pannonia, whence, conducted by their king Attila, they made a wasting campaign in Gaul; but that leader having met with a signal defeat in 451, turned towards Italy, and could scarcely be induced to spare Rome itself and to quit Italy. After his death in 453 the kingdom of the Huns disappeared, its inhabitants having been scattered and lost among the tribes of the Goths and Gepides.

The most dangerous enemies of the Romans were the Goths, to whom reference has before been made. They were a tribe of Germans originally established in East Prussia, on the shores of the Baltic, but had extended themselves through Poland, to the Black Sea, and had spread themselves over the Roman provinces on the Danube. In the third century, Rome found it necessary, or at least convenient, to allow of their establishment in Dacia. This powerful nation, the first amongst the Germans who embraced the Christian religion, was divided into two branches. The Eastern Goths were established on the river Don and the Black Sea, and the Western Goths between the Dniester, the Danube, and the Vistula. As they were assailed by the advancing Huns, and compelled to abandon their settlements about the year 375, the Romans conceded to them other settlements in the interior of their empire. The Western Goths, under their king Alaric, attacked the Romans in Italy in 403, several times assailed Rome itself, and conquered and plundered it in 410. His successor Ataulf led his followers into Gaul in 411, and from thence into Spain, where was erected the largest Gothic kingdom, which from 624 comprehended the whole of the Peninsula, with a part of France and some portions of Africa, and was only terminated in 711, by the victory of the invading Moors at the battle of Xeres.

The Eastern Goths had been settled by the Romans in the country of Mœsia, now known by the names of Bulgaria and of Servia. Odoacer, the chief of two German tribes, the Heruli and the Rugieri, who had served under the Roman standards, became the master of Rome and of all Italy. But he was subdued by Theodoric king of the Western Goths, who thus succeeded to supreme power in Italy in the year 493.

Though Theodoric was one of the greatest characters of his age, the kingdom he founded proved but of short duration. The Emperor Justinian, after his successes in Africa, attacked the power of the Goths, and by his generals, first Belisarius and afterwards Narses, once more, in 554, restored Italy to the dominion of the Greek empire. The Gothic sovereigns then disappeared, and in a few years no trace of them remained except their name, which has been applied to a peculiar style of architecture.

A few years after the fall of the Gothic kingdom, the reater part of Italy fell under the power of the Longo- ards or Lombards. According to some accounts, they ere a tribe from Scandinavia, but according to others, a ranch of the great German family of the Suevi, who in arlier times had inhabited those parts on the Elbe which re now known as Luneburg, and who had, after various xcursions, been settled in Pannonia about 527. They dvanced from thence, in 568, towards Italy, and under eir king Alboin made a conquest of nearly the whole eninsula; a feat which was easily effected, owing to its esolate and depopulated condition. The chief opposition ey encountered was from the city of Pavia, which, af- r a siege of three years, was captured in 572, and made e capital of the kingdom. Lombardy flourished during vo centuries, till it fell under the power of the Emperor harlemagne in the year 774.[1]

The history of Germany between the years 560 and 70 is wholly destitute of the materials necessary to ame a consecutive narrative. The only writer of the eriod was Gregory bishop of Tours, and his attention was holly engrossed by the events of the Frank kingdom hich had sprung up in Gaul, and had begun to decline, e manners, laws, and customs of which he has faithfully presented. The only part of his voluminous work which lates to Germany, is an account of an alliance formed be- veen the Bavarians and Longobards, which offended the ranks, and proved the cause of hostile movements, which, owever, were speedily and pacifically terminated in 589. rom the death of Dagobert in 632, the dominions of the rankish kings of the Merovingian race were gradually iminished. One portion after another fell into the hands f great lay or ecclesiastical feudatories; but these cir- umstances seem to have had little effect on the German ibes. They scarcely interfered in the Frankish contests; nd though not without internal controversies and conten- ons, these were of local and temporary importance only, nd seldom produced extensive or calamitous convulsions. reparations for defence against the Franks were carried n; some fortresses were constructed, and military disci- line was maintained. But the most distinguished feature f the century, was the spread of the Christian faith. A aint from Ireland, with his assistants, laboured amongst e German tribes with great diligence and success. The ross of Christ had been planted among them, and publicly cknowledged as their standard; but the remains of hea- enism, with its superstitions, were cherished by the reat mass of the rude people, and the sacred rites of e Druids were performed in their hallowed groves.

St Columba indeed found almost everywhere Christian riests, but their knowledge was slight, many of their ce- monies were idolatrous, their faith was wavering, and, hat to the Irish saint was most annoying, their depen- ence on the see of Rome slightly if at all acknowledged.

The success of the Irish missionaries is much lauded y the monkish writers of the ages that followed their xertions; and whatever effect they may have produced pon the manners and morals of the Germans, it must be cknowledged that they were successful in bringing that eople into that close connection with the great head of e Christian church, which became, in a succession of nturies, under the guidance of Providence, one of the eans of their advancement in civilization.

During the same period was laid the foundation of ose small sovereign states which successively grew up Germany under ecclesiastical and lay chiefs, who bore e titles of archbishops, bishops, abbots, princes, dukes, counts, margraves, landgraves, and barons. These, in process of time, had the indirect choice of the emperor, who assumed the title of Chief of the Holy Roman Empire, and was elected to that dignity by princes called electors, who were independent, though nominally the household officers of the reigning emperor. The emperor Charlemagne was the real founder of the holy Roman empire, although that name was not given to it until a later period. He was of the race of the Frankish kings, the son of Pepin and the grandson of Charles Martel, and, jointly with his brother Carloman, ascended the throne of Gaul in 768. He was one of those extraordinary characters calculated to change the face of the civilized world. The history of his actions, during a long and glorious reign of forty-seven years, would relate his transactions in France, Spain, Italy, and Germany, but must here be restricted to those which relate to the last of those countries. (See article FRANCE.) The death of Carloman in 771 gave him the sole command of France, and his authority extended over Italy and a portion of Germany. He wished to obtain more power in that direction, and resolved to attack the Saxons, and made religion one of the pretexts for his attempt. The Saxons were a pagan people settled in Holstein and Westphalia, between the Weser and the Elbe, and, like all people in a barbarous state, thought themselves warranted by this independence in making incursions on their neighbours. They were frequently defeated, and made treaties of peace, which they soon broke, and thus continued until they were completely subdued in 803, when Charlemagne settled some of them in Flanders, and others in Switzerland, whilst the country was occupied by a Vandal tribe from Mecklenburg.

This long resistance of so weak a power was owing to the enlistments of the troops of Charlemagne being but for one year, and to the other wars in which he was engaged with the Lombards, the Danes, and the Saracens, as well as with some of the feudatories in his patrimonial dominions. He had long nourished the desire to become emperor of the West, and had negotiated a treaty of marriage with Irene, empress of Constantinople, which would have led to a general union of all Christendom under one head, but which was frustrated by the death of that princess. He was, however, in the year 800, crowned in Rome, by Pope Leo III. and acknowledged as emperor of the West in all the extensive dominions he had obtained. He reigned as emperor fourteen years, and died in 814, at Aachen or Aix-la-Chapelle in Germany, which had been early selected as his favourite residence.

The German empire may be dated from the treaty of Verdun in 843, by which the Frankish kingdom was divided. Lorraine was added to it in 924. Otto the Great brought the kingdom of Italy in 961, and the imperial dominions in that country in 962, into close connection with the empire of Germany, which then for the first time received the appellation of the Holy Roman Empire. But the Italian states were rather feudatories than subjects of that empire, and this slight bond was in a few years dissolved. Bohemia was a part of the empire under Otto, and continued to be so considered until a later period. For a short time the kings of Denmark owned allegiance on account of Jutland, and the king of Poland on account of Silesia, a state of things which continued till 1355. Hungary was also a part of the empire from 1045 till the reign of Henry IV. Prussia likewise, the possession of the Teutonic order, stood in the same relation to the empire from 1230 to 1525, and Livonia from 1205 to 1556.

---

[1] See Luden's *Geschichte des Deutschen Volkes*, 2 und 3 theil; also Sartorius *De occupatione et divisione agrorum Romanorum per barba- Germanicæ stirpis*, &c. 1812.

The Emperor Conrad II., in 1033, united a part of the kingdom of Lower Burgundy with the empire, which thus comprehended Franche-Comté, Dauphiné, the Lyonnois, West Switzerland, Provence, and Savoy. These portions were, however, one after another separated from it; and in 1648, when Switzerland and the United Netherlands were declared independent, none of them remained to the empire but Savoy, Mompelgard, and the bishopric of Basil. The principles which regulated the intercourse of the emperor with the several princes, and of those princes with each other, were grounded, not, as in other states, on charters granted by the chief, but on resolutions adopted at various times amongst the several states in general assemblies. The most memorable of these resolutions were, 1*st*, that of internal peace in 1495; 2*dly*, the Golden Bull, so called from having a seal of gold appended to it. This was agreed to under the Emperor Charles IV. in 1356, and confirmed at two subsequent diets or assemblies, which were held at Nuremburg and Metz. The chief object of it was to secure to the several states the right of independent voting in the election of an emperor. 3*dly*, The treaty of Passau in 1552, or rather that concluded in consequence of it at Augsburg in 1555. This treaty established religious peace, and conferred on the several sovereigns who had embraced the Lutheran religion the free exercise of it in their dominions; and to the subjects the right to change their religion, and to leave the dominions without permission from the princes. 4*thly*, The treaty of Westphalia, concluded in 1648, which extended freedom of religion to those who had embraced the reformed or Calvinistic religion, as well as to the Lutherans.

Germany was divided, in 1500, under the Emperor Maximilian I. into six circles, viz. Franconia, Bavaria, Suabia, Upper Rhine, Westphalia, and Saxony. These were increased in 1512 to ten, by adding to them the circles of Austria and Burgundy, and forming two circles out of that of Saxony, and two out of that of the Rhine. But Lausatia, Silesia, Bohemia, Moravia, and other countries, though encompassed by the empire, were nevertheless not included in it. Each of these circles had at its head an ecclesiastical and a lay prince, who assembled the states of the circle, communicated between the emperor and them, and called their attention to the civil or military affairs of the body. Besides these, each circle had a military chief, generally denominated the field-marshal, who commanded the forces, and had the care of providing subsistence, arms, and other stores. In the assembly of the states a majority decided every question; but the decision required to be conformable to the general laws of the empire.

After the reformation of religion at the treaty of Westphalia, the circles were divided into Catholic, Protestant, and mixed. The circles of Austria, Bavaria, and Burgundy belonged to the first; to the second appertained Saxony; and to the third the remainder.

The imperial dignity was retained by the family of Charlemagne till the year 888. After that time it was elective, although for a long period there was a general adherence to the family which had been once chosen. At the commencement, the emperor was elected by the whole of the princes, whether lay or ecclesiastical; but during an interregnum, which lasted from 1197 to 1272, the highest or arch-princes, called *kurfursten*, assumed the exclusive right of electing, and by a subsequent union amongst themselves, at the election of Charles IV. in 1356, secured the power they claimed. Frankfort was the place of election to which the Archbishop of Mentz summoned the princes or their ambassadors who were allowed to vote; but none of them was to be attended by more than two hundred followers, of whom only fifty were permitted to be armed. All strangers, even sovereigns, and the ambassadors of foreign potentates, were commanded to leave the city on the day of election. After the choice had been concluded, the person chosen, or his representative for him, required to take the prescribed oaths to maintain the golden bull and the several capitulations. He was then led into St Bartholomew's Church, and declared emperor. At an early period the pope was requested to crown the emperor; but in 1338 it was ordered by Louis the Bavarian, that the dignity and power should be assumed without the ceremony of papal assent or consecration. The coronation was fixed by Charlemagne to be performed at Aix-la-Chapelle; but it was afterwards enacted at Frankfort, whence the standards and jewels used on the occasion were removed, part to Nuremburg, and part to Aix-la-Chapelle.

It became usual, during the lifetime of an emperor, to choose a successor to the imperial dignity; and the person so chosen was designated king of the Romans. This institution first arose in 1220, when Henry VII., a son of the Emperor Frederick II., was elected. He was bound to take oaths similar to those enjoined upon the emperor; but during his lifetime he was forbidden to mingle in the public business of the empire. In case of the death, of the minority, or of a protracted absence of the emperor, the golden bull had provided that the Prince of Saxony should exercise vicariate power in Saxony and Westphalia, and the Prince of Alsace similar power in Franconia, Suabia, and the Rhenish circles. They could call assemblies, collect and control the finances, and administer justice; but they had no power to grant imperial dignities or feudal estates. In neither of the circles of Austria or Bavaria was any provision made for the exercise of this vicariate power.

The states of the empire, or general assembly, consisted of the clergy and laity, who held their property direct from the empire. The first comprehended the archbishops, bishops, prelates, abbots, abbesses, and the masters of the Teutonic and St John's orders; the second included arch-princes, dukes-princes, landgraves, margraves, burgraves, graffs or counts, and the free imperial cities. After the peace of Westphalia, the states were divided into the Catholic and the Protestant portions, who on many subjects deliberated and resolved separately. Whilst the inferior princes exercised the executive and legal authority within their own states, those greater affairs which related to the empire in general, and to the respective connection of one sovereignty with another, were brought under the notice of the general assembly, in which the emperor presided either personally or by his commissary, who was always a prince of the empire, and who was attended by an assessor. The assembly was divided into three benches or colleges, in which every thing was decided by a majority of voices; but at a subsequent sitting they were united, and then the majority of the three benches determined the final resolution. Many subjects were intrusted to the examination of imperial deputations or committees. The power of making war or concluding peace belonged to the assembly, but was sometimes intrusted solely to the emperor, though only in pressing emergencies. The emperor had originally the power of nominating to the ecclesiastical dignities; but the popes gradually so intruded their authority, as to reduce the monarch's power to almost a shadow. After the peace of Westphalia, the empire was divided between the three religions. In the Catholic states, the pope and the bishops had usurped the judicial power, and administered it according to the canon law. In the Protestant parts, all the juridical power of the church was abolished, and the affairs of religion were left to the management of consistories chosen from among the subjects, in most cases on the nomination of the princes.

The power of coining money appertained originally to e emperor, but was gradually obtained by several of the iefs of the respective states; but the fineness and the eight of the coin were directed by the authority of the nperor and the general assembly. The tolls on certain vers and roads, the regulation of the great fairs of Frank- rt, Brunswick, and Leipsic, and the conveyance of letters post, as well as providing post-horses, were the regalia the emperor; and the latter were granted hereditarily to e prince of taxes, whose successors, even to the present y, have some power and some profit connected with em. The degrees in the universities were conferred in e name of the emperor; and, through a prince named by n, called the Pfabzgrave, the doctors, licentiates, advo- es, solicitors, notaries, and other legal officers, were ad- tted to practise their professions in the courts of law.

The finances of Germany, viewed as one empire, were ler the direction of the general assembly. The contri- ions were called Roman months, each of which amount- to a force of 20,000 infantry and 4000 cavalry; and the nber of these months which were granted to the em- or was adapted to the occasion that required them. ese were divided among the several states, and called t ir contingents. They were, however, in process of e, frequently converted into payments in money, at sti- ated rates. In later times each Roman month was mated at 128,000 florins, or about L.12,000 sterling. is tax was paid either at Augsburg, Frankfort, Nurem- g, or at Leipsic, and the collectors of it were called nning-meister.

any of the individual princes were under greater or le restraint in the exercise of power, from the rights of th r state assemblies; and when there was a collision be- t en them, an appeal was made to the imperial tribunals. T those courts the princes were answerable for the debts th y incurred, and by them their dominions were on some o asions put in a state of sequestration; but in other of th principalities there were no assemblies of the states, a consequently less limitation of powers, though in them th sovereign could be brought under the authority of the in erial chamber, and obliged to fulfil his engagements.

his sketch of the ancient constitution of the German e ire is interesting, from the length of time which it last- e and from having, during ten centuries, with all its com- pl ity and impediments, preserved, among the many inde- p lent states of which it was composed, a feeling of na- ti ality, which is still cherished by all who are descended fr the rude and ancient tribes of German origin. This con- st ution gave to Germany but little other unity, and less p er, and rendered the greatest of the European king- d s the weakest of them all. It kept them, however, from su ring the misery of a conquered and an oppressed peo- pl and has led them to a degree of intellectual culture, in hich they have been equalled by few, and exceeded by n ther nation. Perhaps the distribution of the territory in ich small sovereignties was one of the most effectual m ns of advancing and securing that reformation of reli- gi , which all Protestants regard as one of the greatest bl ings to the whole human race.

he history of Germany in modern times is so much co ected with that of the rest of Europe, especially dur- in he wars of the last and the present century, that a nar- ra n of it would only be a repetition of what is to be found in is work under the heads of Europe, France, and es- pe lly Britain; and to them the reader is referred.

e peace of Presburg in December 1805 first gave oc- ca n for the dissolution of the ancient constitution of Ger- ma . By that treaty the Dukes of Bavaria and Wurtem- be were raised to the rank of kings, and the Prince of Ba n to that of an independent sovereign. Soon after- wa s (28th May 1806) the arch-chancellor of the empire de red to the assembled diet, that, though contrary to law, he had nominated Cardinal Fesch, the uncle of Bonaparte, as his coadjutor and successor; and on the 12th of July the new kings of Bavaria and Wurtemberg, and sixteen other princes, formally announced to the Emperor Francis II. their separation from the empire, and invited the other princes to join them in a new alliance. The Emperor Francis on the 6th of August issued a declaration of his withdrawing from the head of the empire, abandoning the title of Emperor of Germany, and assuming that of Emperor of Austria.

In the room of this dissolved constitution, of nearly a thousand years' continuance, the several states which had been accomplices in its destruction, with some others added to them, formed what was called the Confederation of the Rhine, which, by February 1808, had received the adhesion of most of the princes, and placed Bonaparte at its head, under the title of protector. Two years afterwards, the protector, by his sole decree, united the rivers Scheldt, Meuse, Rhine, Ems, Weser, and the mouths of the Elbe, to France, and robbed of their dominions several of the smaller princes, whom he had contracted to defend. With these augmentations he continued his aggressions till the dispersion of his army in Russia.

As the events which produced the deliverance of Germany from the yoke of France belong to the history of that country as much as to this, our notices of it here must be brief. After the destruction of that vast army which penetrated into Russia, almost all the states of the north of Germany, with Prussia at their head, declared war against France. An army was quickly collected from the French conscription, and, with a wonderful celerity, Bonaparte, at its head, was enabled to penetrate into Saxony, to threaten Prussia, and exhibit a force which he supposed would overawe Austria. The battles of Lutzen and Dresden, in 1813, produced an armistice, during the continuance of which negotiations for peace between Russia and Prussia on one side, and France on the other, were carried on under the mediation of the Emperor of Austria. But as peace could not be concluded, Austria was induced to join the allies against France. During these periods a spirit had risen in Germany which animated all classes of its inhabitants, so that those powers which still clung to the interests of France could place no reliance on the support of their subjects. Bonaparte, overpowered by numbers, with an army of raw troops from his own dominions, and with troops of doubtful fidelity from the dominions of his allies, was surrounded, and, after being compelled to retreat from Dresden, fought the important battle of Leipsic against the armies of Russia, Austria, Prussia, and Sweden. The issue of that battle was not considered as doubtful even from its commencement; but, during the contest, the Saxon division of the army marched from their station in the French line, and took up their position with the Prussians. The result of the battle was a hurried retreat from Leipsic to the frontier of France, which was then the river Rhine. On the retreat to the Rhine, the shattered remains of the French army were interrupted by the forces of Bavaria. A battle was fought at Hanau, about twelve miles from Frankfort, which, though gained by the French, tended only to hasten their flight, and led to the loss of much that remained of their stores, arms, and ammunition.

By the end of the year 1813, the French were totally expelled from every part of Germany, and the occupation of Paris by the allies, early in 1814, led to general tranquillity. The Congress of Vienna soon afterwards met, and never was a body of plenipotentiaries plunged into such a labyrinth of difficulties. The great extent of country which had been delivered, and was without any government; the number of claims urged either from previous possession, or from active service in effecting the deliverance; were such as to perplex with difficulties which appeared to be nearly insuperable, and, in whatever way they were terminated, must necessarily have left great dissatisfaction. They were, however, so settled as to leave Germany in the state described in the preceding pages; and whether they could have been adjusted with more regard to the principles of equity is not for us to decide.

The return of Bonaparte from Elba produced most gigantic efforts upon the part of all those smaller sovereigns who had been reinstated in their dominions by his downfall. The number of troops actually mustered and prepared to march when the battle of Waterloo took place and suspended them, amounted to more than 1,200,000 men. They were not indeed all armed, but many more men could have been raised if arms for them could have been procured. These efforts, added to the costly exertions made in the war of the deliverance, have encumbered with debts almost every state, as is noticed in the detailed account of them. These debts, however, have not been solely created by the events in question. The ephemeral kingdom of Westphalia, formed for Jerome Bonaparte, extended over Hanover, Brunswick, and Cassel, as well as the circle from which it was denominated. During his government, all the different portions of his kingdom had incurred vast debts in executing his projects. These debts were owing to individuals or corporate bodies within the dominions attached by the congress to their new sovereigns; and the princes, for the sake of the people, were compelled to assume the debts, and provide means for their liquidation, and the payment in the mean time of the interest. Thus the ungrateful task of providing for the expenditure attending the subjection of their states, as well as for their liberation, became one of the first duties on their resumption of power. This odious consequence of former circumstances has been industriously improved by the enemies of tranquillity, and has created considerable discontent.

These feelings of discontent were chiefly confined to writers in periodical papers of the smaller kind, and to associations amongst the young men in those universities in which the discipline was the most relaxed. The demonstrations of this dissatisfied state of the public mind were few, and scarcely noticed except in narrow circles. The murder of Kotzebue by Sandt, and a similar attempt on the life of Ibell, the minister of Nassau, were tokens of great excitement amongst a few fanatics; but the judicial inquiries which followed these transactions seemed to the governments to prove that the mischievous views of insurrection or assassination were confined to a very narrow circle. There was no interruption to the full exercise of the powers of the law, nor any necessity for increasing the military establishments. The Revolution in Paris in 1830 produced, however, considerable excitement in several parts of Germany, particularly in Hanover and in Saxony, and also in Brunswick, though in the latter country it was more owing to the personal character and conduct of the sovereign, which led to his deposition and to the investing of the power in the hands of his brother. In Hanover, the suspension of the university of Göttingen, and the mild but firm measures of the government, soon led to tranquillity; and in Saxony, though some mischief was effected, it was but of short duration, and the kingdom soon returned to that tranquil state which is habitual to the greater part of its inhabitants. The establishment of the present German confederation, consisting of ambassadors from all the states, in number proportioned to their extent and population, has concentrated the power of the whole body of the princes, and appears calculated to give stability to ancient and respected institutions. These representatives were seventy in number, but are now reduced to sixty-nine,[1] as appears by the table which follows; and in some cases they act by a committee of seventeen. In the general body, two thirds are required to make a law; in the smaller body a bare majority is sufficient, but in both assemblies Austria and Prussia have a great preponderance. Austria is the president in both these bodies, and has the casting vote when an equality of opinions is experienced. It is not our design to condemn or applaud the constitution; but it is powerful to suppress insurrection, and to propagate general regulations, and is said to have been found highly beneficial in the arrangement of differences between the governments of the several states of which it is composed.

Within the limits of Germany are portions of kingdoms, parts of the territory of which are not within the sphere of the confederation; thus Austria, Prussia, the Netherlands, and Denmark, have parts only of Germany within their dominions, and therefore will here receive such notice as is merely necessary to give a view of the whole of Germany. Austria and Denmark have already been noticed in this work, and the kingdoms of the Netherlands and of Prussia will occur in their alphabetical order.

The four kingdoms of Bavaria, Hanover, Saxony, and Wurtemberg, are too important to be wholly included in a general article. Bavaria has been already treated of separately, and the other three will be noticed in their proper places.

According to its present boundaries, Germany extends from 45° to 54° 20′ north latitude, and from 5° 43′ to 20° 50′ east longitude from London. It is bounded on the north by the German Ocean, by Denmark, and the Baltic Sea; on the east by West Prussia, Poland, Cracow, Gallicia, and Illyria; on the south by the Adriatic Sea, Italy, and the Helvetic provinces; on the east by France and the kingdom of the Netherlands. Its whole extent, including rivers and lakes, is 248,832 English square miles.

The southern part of Germany is either covered or penetrated with steep mountains, one part of which extends from the Alps, and the other from the Carpathian range. These mountains gradually lose themselves in advancing northward; and from the last of them, the Hartz, upon the confines of Hanover, begins that vast plain which extends over the north of Germany, through Prussia and Poland, and a considerable part of Russia. This plain was probably covered by the water long after the more southern parts had emerged from the ocean, the evidences of which are apparent in the turf moors of the sandy districts, where expensive embankments and dikes are necessary to preserve the land from inundation.

The soil is generally productive. The plains in the north have indeed much arid sandy land; but nature has provided along the borders of the rivers some rich and fruitful soils, where the most abundant harvests are gathered. The south has also on its mountains much barren or slightly productive land; but the beautiful valleys and small plains between the hills rival in fertility the best alluvial lands on the banks of the northern rivers. In general the soil in the north is heavy, and in the south light; the former most adapted for corn, and the latter for vines. The best soil is in the middle, between the mountains and the sandy plains. In Bohemia, Silesia, Franconia, Saxony, and on the Rhine, the proportion of good soil is much greater than in the north or the south.

Some of the loftiest mountains of Germany are those springing from the great mass of the Alps, and divided into the Rhætian and the Noric; and several of the peaks of these reach the line of perpetual snow. The eastern branch of the Noric chain runs through the Austrian dominions, and loses one part of that chain in Silesia, whilst another enters Hungary. The other branch runs through Bavaria and Wurtemberg, to the west of the Black Forest, and is connected with the Odenwald, the Fichtelgebirge, and the mountains of Thuringia. It stretches to the Hartz, and the mountains through which the Weser forces its passage, oon after which it is lost. Several other chains branch from these greater ones; and some of their peaks attain a considerable elevation. The principal mountains, and their height above the level of the sea, are as follows; but in their progress to the north their gradual declension in height is remarkable :—

---

[1] This diminution of the number has been caused by the duchy of Saxe-Gotha having been divided between two other states.

The Rekuhl (the highest in Pomerania)	280

The mountains are generally covered with forests; to the southward, where they are the most lofty, with pines; and to the northward, with various deciduous trees. If at the present day the *terra sylvis horrida* of Tacitus cannot be found in Germany, it is still the most abundantly wooded territory in Europe.

Germany has seven large rivers which pass through it to the sea; and in their passage receive the various smaller streams which issue from the mountains, and spread fertility over this well-watered country. The Danube rises in the dukedom of Baden, becomes navigable for small craft at Ulm, receives the large rivers Lech, Iser, Inn, Ens, and March, and, after a course of 430 miles, exclusively of its curvatures, waters Hungary in its way to the Black Sea. The Rhine, rising in Switzerland, and navigable from its entrance into Germany, has a course, exclusive of its windings, of 460 miles, before it enters the kingdom of the Netherlands. In its progress it receives the navigable rivers Neckar, Lahn, and Moselle, the Saar, the Roer, and the Lippe.

The Weser rises in middle Germany, from two springs which form the Fulda and the Werra, and at their junction takes the name which it carries to the ocean, and under which name it runs, without noticing its bendings, 190 miles. It becomes navigable at Minden for boats, and at Vegefach, near Bremen, for ships. The Elbe, like the Weser, from its rise to its junction with the ocean, is wholly a German river. It becomes navigable near its source, runs a course of 520 miles, and is the most considerable channel of commerce with foreign countries, through the ports of Hamburg and Altona. It receives the navigable rivers Moldau, Eger, Saale, Havel, Spree, Ilmenau, and Steckinitz, besides fifty smaller streams. The Oder becomes navigable for boats at Ratisbon, and running, in the Prussian part of Germany, a course of 380 miles, empties itself into the Baltic Sea in Pomerania. It receives the rivers Bober, Neisse, and Warthe, besides many smaller streams. The Eloch is the only German river which runs to the Adriatic Sea. It passes through the Tyrol, and only becomes navigable after it has entered Italy. The Ems is a river of short course, rising in Prussia, and passing through the province of East Friesland, now belonging to Hanover, whence it becomes navigable, and soon enters the sea near the city of Emden in two branches.

The forming a junction between these great rivers, by means of canals, is an object of vast importance, and some progress towards effecting it has been made. The Holstein Canal unites the German Ocean with the Baltic Sea from the river Eider. The Plauen Canal unites the Havel with the Elbe, or rather facilitates and shortens the passage. The Finnow Canal forms a communication between the Havel and the Oder. The Frederick William's Canal unites the Spree and the Oder. The Pappenburg Canal is designed to unite the Ems with the Elbe. Lastly, the Vienna Canal is now completed, and forms a communication between the Danube and the Adriatic Sea.

The whole of Germany being in the temperate zone, though, from the variations of elevation and the difference of latitude, it differs in climate, is generally very healthy. The most mild and beautiful are the middle provinces, between the 48th and 51st degree. In the south, under the influence of the Alps, the air is raw and cold; whilst in the plains and open valleys the climate of the finest parts of Italy is enjoyed. The northern provinces are colder, damper, and more ungenial, and near the stagnant lakes unwholesome. The weather undergoes extreme variations, and the frost is frequently seen at a late period of the year. The inhabitants there too feel the effect of heavy fogs, and sometimes of tremendous storms. No volcanoes are now in existence; and though the remains of them are to be seen in many places, they are not supposed to have been in activity since the antediluvian ages. Earthquakes are scarcely felt, and have never been injuriously experienced; and the country is free from the musquitos, which so much annoy the inhabitants of Italy. Vines, maise, and rice, grow as far north as latitude 51; but beyond that they do not arrive at full perfection. The olive and the silk-worm are only raised on that small portion of Germany to the south of the 46th degree.

The original German horses are of a very inferior race, and the specimens of them, where they have not been improved by the intermixture of other breeds, generally bad; but from this must be excepted those of Mecklenburg, East Friesland, Holstein, and Luneburg, which, for draft or for heavy dragoons, are admirable races, and have been propagated over all Europe. Horses for pleasure, or for mounting light cavalry, must be brought from other countries; but the jennets, a light small breed, are good and quiet. Asses are not common even in the southern part of the country. Mules are to be seen in Hanover, near the Hartz Forest, and in the Tyrolese portion of Germany they are the common beasts of burden.

The cows are of various breeds; but the handsomest are those from East Friesland, Oldenburg, Holstein, and the other provinces on the borders of the German Ocean, though generally known under the name of East Frieslanders. The Hungarian breed prevails in many parts, but is esteemed more for the ease with which the animals are fattened than for the purposes of the dairy. A third sort of cows is the Swiss breed, which does not come wholly from the Alpine regions, but is furnished by Wurtemberg, and a part of Bavaria. The breed of Germany, originating from the mixture of these races, is well adapted for the dairy; but, either from want of appropriate qualities in the animals, or from the imperfect manner of fattening them, the oxen, when killed, are seldom more than 500 pounds weight, and the average of them considerably lighter. Some attempts are now making to improve the breed, by the introduction of the Tyrolese bull; perhaps the most perfect animal of the cow kind for meat and for draft, and which, when crossed with the best milkers, produces the most complete cattle. The common practice in Germany, of killing the calves from ten to sixteen days old, produces very bad veal; but some of the beef, especially near the banks of the Elbe, is excellent.

The proper German sheep are a mixture of the original coarse-woolled race, crossed by a breed from Ardennes. In a part of Illyria they have the sheep of Padua. The fine-woolled sheep of Spain have, however, been introduced by many of the princes, and have been vastly extended, especially in Saxony, Silesia, and Brandenburg, and will probably, at no distant period, be the principal, if not the sole race. The badness of their flesh is of less consequence in Germany than in England; because, in the former country, it is not worth more than the annual clipping of the wool, which can be sent to richer countries, where they can afford to pay high prices for it; but the flesh must be consumed at home, and therefore sells for little.

Goats are common in all the states, but are only to be seen in large flocks in the more mountainous parts. Swine are the most important kind of live stock in Bavaria, Westphalia, Hanover, Mecklenburg, and Pomerania. They are of three different breeds; the long white, bent in the back; the short white, or yellow, with the same kind of back; and the black, or yellow, of a short make; but these different breeds are becoming much mingled together.

The forests of Germany abound with untamed animals, which afford sport to its princes and nobles, and furnish a considerable quantity of aliment to the higher and middle classes of the people, as the noble sportsmen generally sell their prey, and are obliged to dispose of it cheap. Wild deer of various kinds, and wild swine, are very numerous in many parts of the country. With them, foxes are found in some districts in prodigious numbers; but the hunting of these animals is less an object with sportsmen in Germany than with us, as the lynxes are very numerous, especially in the mountains in the south, and the chase of them is found to be the most exciting of all rural sports. At a hunting on the estate of one nobleman in Bohemia, during three days of 1818, more than 12,000 head of game were killed; and in Saxony between 2000 and 3000 hares were shot in one day, and sold for about one shilling each. There are bears in the southern parts, in Illyria, in the Steyermark, and the Tyrol, of the small black kind, more dangerous to the bee-hives, and the smaller animals, than to man. Wolves are few now, and only found in the Trans-Rhenish provinces. In some of the mountains the beaver is found, though but rarely, and some other animals, principally valuable for their fur. The most annoying animal is the field-mouse, of a species called the hamster, which is found in thousands in Saxony, and does incredible injury to the productions of the soil. In the months between the 9th May and the 9th September 1817, the corporation of the city of Gotha paid rewards for killing 89,565 of these mischievous animals.

Domesticated birds are very plentiful, but especially ducks and geese. The latter form an important portion of the food on many of the farming establishments, especially in Pomerania, Bohemia, and the Steyermark, where most houses in the country cure from fifty to a hundred for their winter consumption. Wild birds are more numerous in Germany than in any other part of Europe. Wild geese, bustards, grouse, blackcocks, woodcocks, wild ducks, widgeons, teal, and snipes, are most abundant. Besides these, the smaller kinds of birds, as larks, thrushes, and sparrows, and the singing birds, especially bullfinches and canary birds, are plentiful. The latter are chiefly taken in the Hartz Forest, and are circulated throughout all Europe.

The three seas which border on Germany abound with fish. Besides the kinds which are caught in the ocean, the Baltic Sea and the Adriatic furnish their peculiar species. Amongst those of the former are the dersh and the klipfish (*anarchicos*); and of the latter the tunny, the sardinia, and many others. The greater part of the fish consumed in Germany is, however, the produce of the rivers and lakes, which supply in great abundance eels, lampreys, trout, salmon, sturgeon, perch, pike, salmon-trout, barbel, carp, craw-fish, and many others. With these various kinds the markets in the cities are most profusely supplied.

The rearing of bees in the north, and especially in Lausatia, is productive of much honey and wax, which form important articles, both for domestic use and for foreign trade.

The great production of Germany, as of every other European country, is grain of various kinds. Wheat, rye, maize, rice, barley, oats, beans, peas, and buckwheat, are the most important of these. In the south, more wheat than rye is grown; but in the north, the proportion of rye to wheat is eight to one. In the north, most oats are cultivated; in the south, more barley. Maize and rice are peculiar to the south; buckwheat and peas are alike in every part.

The productions arising from garden culture are very great. Potatoes are sometimes cultivated with the spade, sometimes with the plough; but the increase of their growth has been very rapid of late years, and probably furnishes as much human aliment as grain. The cabbages of all the Brassica tribe receive much attention, and are raised in great quantities. Turnips are cultivated with little care, merely as food for man, and are not extensively used for feeding cattle. The superior kinds of fruit are best in the middle and southern provinces; but in the north the apples, plums, and pears, are good and most abundant. The Pearmain apple, which has spread throughout all the countries of Europe from Germany, is found in the highest perfection in Stettin, Bostock, and the Tyrol. Chestnuts and almonds are almost exclusively grown in the southern parts, towards Illyria and the Tyrol; and in the same vicinity the melons and other fruits, which in our climate and the north of Germany require artificial heat, are raised in the open air.

Vines were originally planted in Germany by the Romans. They are now cultivated successfully on the banks of the Rhine, the Maine, the Moselle, the Danube, the Mur, the Etsch, and the Save, where they produce wine as highly esteemed as any in Europe. The most valued of all the wines is that produced on the banks of the Rhine, known in England by the name of Old Hock, from the vineyards of Hockheim, where the best kind is made. The principal sorts, from the places of their growth, are denominated Johannisberg, Rudesheim, Hockheim, Markobrunn, and Lieb-frauenmilch. The next in value are the wines of the Maine, called Leisten wine, Stein wine, and Steyer wine. The wines from the Danube are next in estimation, and to them succeed those from the Tyrol and the banks of the Moselle. The other wines near the lake of Constance, and in Bohemia, are much inferior; and those produced near to Naumberg, Jena, and Meissen in Saxony, and to Zullichau in Silesia, are of very indifferent flavour, specially after a moist summer, and scarcely merit the ame of wine, though, from their great abundance, they ecome very useful to the inhabitants.

Neither the quantity nor the quality of the oil produced om olives in Germany is material; it is confined to a nall district of the south. Great quantities of rape and nseed oil are expressed; and for the more common puroses, the oil of herrings, seals, and other aquatic animals, very abundant.

But the staple production of Germany is flax, which grown in almost every village, and is spun into yarn. he best is produced in Silesia, in Westphalia, in Hanoer, in Brunswick, and in Bohemia; but even these kinds not attain a length or fineness of fibre equal to the flax Flanders. Hemp is raised in Baden, Wurtemberg, estphalia, Hesse-Darmstadt, and Luneburg, but scarce- produces sufficient for the consumption of the country. obacco has been long cultivated in Baden, on the Rhine, d near Magdeburg, and during the existence of the ench continental system had been very much extended; t the return of peace checked its progress, and the culation of it is again confined to those parts here menoned, where, from long habit, it has become almost ingenous. Various roots were cultivated for the proiction of sugar during the continuance of that system, t they now scarcely deserve notice, as they are nearly andoned. Woad, saffron, annise-seed, cummin-seed, ps, rhubarb, camomile flowers, and Iceland-moss, are tive and considerable productions. The forests of Gerany, besides their abundant supply of fuel to the inhatants, furnish much wood, both for building houses and ips; and if ever the water communication should be ich extended, so as to bring the largest trees with faity to the shores of the ocean, they will become a most luable source of wealth.

No part of Europe yields a greater variety or abundance mineral productions, and in no part of the world are the nes worked with so much skill or so much economy. ecious stones are discovered in many parts; rock-crys, amethysts, topazes, are found in Bavaria; calcedony, ate, petchstein, and porcelain-jasper, in Bohemia; batès in many parts; marbles, gypsum, and alabaster, in hemia; alum near Töplitz; rock-salt and Glauber salts in rious parts; and abundance of the earths calculated for king earthenware, from the coarsest description to the est porcelain. Fossil coal is found in many districts, d much of it is consumed; but the cheapness of wood, d the prejudices of the people against the use of it in eir houses, has operated to prevent the mines from ing completely explored or worked to anything apaching the extent of which they are capable. Gold procured, though in very small quantities, by washing, Saltzburg, in Bohemia, in the Rammelsberg, and in Siia. Silver and cinnabar are raised from the mines of Erzgebirge in Saxony. Iron, copper, tin, lead, canine, bismuth, cobalt, nickel, titanium, arsenic, and alst every other mineral, is more or less raised from the nes. The abundance of mineral substances everywhere ttered, and which it would be difficult to enumerate, e promoted the study of mineralogy, and given birth the school of Freyburg, whence, under the direction Werner, the mineralogical knowledge of the earth has en widely extended.

The annual supply from the mines of Germany is as ows:

Gold	1,456 ounces.
Silver	984,000 do.
Copper	39,000 hundreds.
Lead	191,200 do.
Tin	7,800 do.
Iron	2,400,000 do.
Quicksilver	6,180 hundreds.
Cinnabar	7,800 do.
Cobalt	16,500 do.
Calamine	82,800 do.
Arsenic	10,600 do.
Antimony	2,400 do.
Rock-salt	5,150,000 do.
Fossil coals	20,000,000 do.

The population of Germany has been vastly increased within the period which has passed since the conclusion of the revolutionary year. By the several censuses furnished by the respective states to the congress of Vienna, it appeared that the whole number of the inhabitants was 30,355,069, which in sixteen years has increased to 36,491,019, as is thus seen.

States.	Inhabitants.	Square English Miles.	Votes in the Assembly or Diet.
Austria	11,645,000	78,912	4
Prussia	10,010,755	70,549	4
Bavaria	4,037,017	30,997	4
Saxony	1,497,568	7,200	4
Hanover	1,549,000	14,720	4
Wurtemberg	1,562,033	7,524	4
Baden	1,201,300	5,803	3
Hesse-Cassel	649,800	4,352	3
Hesse-Darmstadt	720,000	4,112	3
Holstein	410,385	3,691	3
Luxemburg	305,120	2,347	3
Saxe-Weimar	232,704	1,408	1
Saxe-Coburg Gotha	156,639	1,024	1
Saxe-Altenburg	114,048	491	1
Saxe-Meiningen Hilburghausen	129,588	875	1
Brunswick	250,100	1,514	2

Bremen	49,000	72	1
Hamburg	154,000	134	1
	36,491,019	251,418	69

The inhabitants are of two original races; the ancient Germans and the Sclavonians. The former are divided into High and Low Germans, speaking a language somewhat different, but possessing great similarity in habits, characters, and dispositions. The Low German, or, as it is called, *Platt Deutsche*, prevails among all the people in Lower Saxony, Westphalia, Holstein, Mecklenburg, Brandenburg, and Pomerania; but as the service in the churches, and the instruction in the schools, is in High German, all even of the peasantry understand that language, though they prefer their own dialect. In the southern parts, where only High German is spoken, the peasantry use a *patois* which is scarcely more intelligible to those unaccustomed to it than the *Platt Deutsche.* The descendants of the Sclavonians reside all to the eastward of the Elbe. They retain their original language, with a great mixture of German words; and they are far behind their neighbours in cultivation, but are an industrious and patient people. They form nearly one sixth of the inhabitants. In the south are some few of Italian origin; and colonies of French, originally Protestant refugees, are established in many places, where they retain a connection with each other, founded upon privileges granted at the time of their emigration. But all these scarcely amount to more than 250,000. The Jews are 248,749 souls; of whom 83,077 are in Austria, 57,353 in Prussia, 22,000 in Bavaria, 8319 in Wurtemberg, 8000 in Hanover, 8300 in Hesse-Darmstadt, 15,079 in Hesse-Cassel, 14,378 in Holstein, 16,000 in the free cities, and the remainder are scattered over the other states.

By the terms of the confederation, the three Christian sects, Catholics, Lutherans, and Reformed, are on an equal footing in all the states of the union, and the religious profession of the princes has very little influence upon that of the subjects. The Catholics are the great majority in Austria, Bavaria, Baden, and Luxembourg, and form a numerous body in Prussia, Wurtemberg, Hesse-Darmstadt, Hesse-Cassel, and Hanover, amounting in all to 21,000,000 individuals. The Protestants of the two confessions have approached each other so nearly as to form almost but one church, and in many parts they are amalgamated together. Their whole number is about 14,000,000. The smaller Christian sects, Menonites, Hussites, Moravians, and a few of the Greek church, are not together more in number than the Jews, who, as before stated, do not exceed 250,000.

The knowledge of the German people probably exceeds that of every other. They have men of eminence in every department of literature, and can enumerate those who have made discoveries or improvements in every branch of science. It is not, however, so much from the merits of their eminent men, great and useful as they have been, as from the general diffusion of knowledge, that the character of the nation must be estimated. Its literature is not the work of its princes and nobles, but arises from the general taste for reading and accumulating knowledge which so extensively prevails, and which descends lower in the scale of society than in almost any other country of the civilized world. Although for two hundred years literature has prevailed much in Germany, it was only about the middle of the last century that, by the poets and critics, the language became polished, without diminishing its force, and was purified from many of those vulgarisms which had disgusted the English, French, and Italian literati. The learned men had more sedulously studied the ancient languages of Greece and Rome than the improvement of their own; but, in the middle of the last century, a race of authors appeared, with whom arose the commencement of the golden age of literature. Gotsched, Lessing, Adelung, and Campe, were amongst the first who imparted to their countrymen the knowledge of the powers and of the beauty of their native tongue. Poetry soon lent its aid, and furthered what the prose writers had begun; it broke forth suddenly as from a dark cloud, and threw a radiance on almost every subject which, in any age or country, the muse has ever attempted. With Haller, Gellert, and Hagedorn, began that chain of poetical writers which has continued to be extended to the present day. The poetical epistles of Michaelis, Ebert, Gotter, and Jacobi, will ever be read with delight. In descriptive poetry Von Kleist, Thümmel, and Wolfgang, have been distinguished; but especially Goethe, whose name is known in every corner of Europe. In satire, Rabener, Musæus, Lichtenberg, and Falk, excelled; in elegy, Holtz, Bürger, Weisse, Schmidt, and Herder; in fables, Gellert, Lessing, Willamow, and Pfeffel; in poetic tales, Wieland, Blumauer, Rost, and Nicolay. The name of Klopstock will ever be reverenced by those who venerate heroic or religious poetry. The lyric poems of Schiller, of the two Schlegels, of Bos, and Ramler, are beautiful specimens of the powers of the German language. Amongst the most eminent of the poets of Germany the name of Goethe cannot be passed over without some mention being made beyond the bare announcement. He has been, during a long life recently closed, the wonder and the delight of all who can understand his language. His works embrace every species of poetry, and are all marked with originality, force, pathos, and nature. He appeared with wonderful applause as a writer, first in 1773, and continued to interest, amuse, and instruct his country during more than fifty years, retaining to the last his powers of critical reflection and of accurate and spirited composition. The theatrical productions have kept pace with the other species of poetical composition. In tragedy, Schiller, Goethe, Lessing, Collen, and Grillparzer, have distinguished themselves; whilst Ifland, Kotzebue, Brand, Grossman, Schroeder, and a host of other writers, have appeared in comedy.

German writers of prose have been neither fewer nor less able, though their names have not been so far extended in other countries as those of the poets and theatrical authors. In religious compositions, Mosheim, Sack, Jerusalem, Spalding, Zollikofer, and Teller, are destined to futurity, after having delighted and edified the existing generation. In epistolary writing, few in any language have exceeded Gellert, Winkelman, Abt, and Garve, whilst Mendelsohn has been unrivalled in his dialogues. The race of novel and romance writers has been too numerous to be recited; and the latter have displayed a power over the human passions and feelings which has scarcely been equalled by the writers of other nations. In didactic writings, those of Scheibart, Lessing, Winkelman, Iselin, Sonnenfels, Moser, Zimmerman, Eberhard, Botticher, and Forster, have displayed great talent; and on subjects of education, Basedow, Campe, Trapp, Salzman, and Pestalozzi, have discovered vast powers of mind directed to one of the most important subjects.

In classical literature the Germans have thoroughly imbibed the spirit of the ages when Greece and Rome were at the highest pinnacle of literary glory. The names of Ernesti, Heyne, Gesner, Camerarius, Fabri, Wyttenbach, Wolf, and Scheller, are familiar to the Latin scholars of every country; as are those of Michaelis, Hottinger, Von der Hardt, Eichorn, Griesbach, and Paulus, to the Greek student; but perhaps, of all the classical scholars of Europe, none have equalled the stupendous learning of the elder Schweighæuser, whose edition of Herodotus, with his lexicon, and his extracts from Polybius, Athenæus, Arrian, Simplicius, Epictetus, and others, have rendered him an object of admiration to the learned of every country.

The Germans have been ever distinguished for that diligence and patience in examination which are the great requisites in geographical and statistical authors. None in any country has exceeded Busching, and many living authors are now following his steps with equal success.

The Germans claim the honour of having been the re-ivers of the Grecian mathematics, and the glory of having ascertained, by their countryman Copernicus, the true ystem of astronomy. Kepler is considered as the father f dioptrics, Tschernhausen the inventor of burning lasses, Leibnitz the discoverer of the differential calculus, nd Lieberkuhn the greatest improver of the solar microcope. Euler was distinguished by his powers of analysis; nd Kepler, Mayer, Herschel, Bode, Von Zach, and Olers, by their skill in astronomy. Metaphysics engaged e close attention of Wolf, Leibnitz, Kant, and their holars, Fichte, Schelling, and Platner.

Although in natural history Germany has produced neier a Linnæus nor a Buffon, yet Blumenbach, Zimmeran, Pallas, and Fabricius in zoology; Haller, Gleditsch, Iofman, and Sprengel in botany; and Werner in minelogy, would not be unfit associates of those great names.

In natural philosophy the Germans claim for Guerike the iscovery of the air-pump; for Fahrenheit the thermoeter; and for Hausen the invention, and for Marun the erfecting, of electrical machines; and they are proud to eckon amongst their chemists the names of Stahl, Hofan, Margrof, Born, Klaproth, and Humboldt. In mediine, besides Paracelsus and Stahl, they boast with great eason of Hofman, Tissot, Haller, Unzer, and Huefland, ith many others of great though inferior name.

In jurisprudence the Germans long took the lead in urope; and in theology Luther and Melancthon have, y the translation of the sacred books, and by their wriings, produced a mighty change through all the most enghtened nations of Europe.

It is, however, somewhat singular, that in a country of o much learning and such research, in which antiquities ave been sedulously studied, where the numismatic colections are so numerous, and where ancient documents re so carefully preserved, scarcely any historian has apeared who deserves a higher name than that of a chroicler.

The fine arts have been cultivated, especially music, ith much success. No nation has produced more celerated composers than Gluch, Handel, Haydn, Bach, and, bove all, perhaps, Mozart. Statuary has been practised ore by Italians in this country than by natives. Painters ave risen to no very great excellence, with the exception f Albert Durer, Kranach, and Holbein; but to those of more recent date must be added Mengs, and, in our wn time, Angelica Kaufman, Hackert, and one or two thers.

The circulation of books, produced from the pens of ten housand writers, is facilitated by the two fairs of Leipsic, o which the publishers from all parts of Germany resort vith the new works they have printed at their own resilences. This general rendezvous becomes the focus of iterary information. The publications are made known, heir respective merits are discussed, and the different ooksellers exchange with each other the productions of heir respective provinces, which are thus spread over the xtensive country in which the language is used with reat regularity, and at a very trifling expense in adertising.

One evil is much complained of, namely, the want of proection for literary property; which arises from the great umber of sovereigns in whose dominions the same language is spoken. The best productions of the north are requently pirated in the south. The king of Saxony has ndeed prohibited the circulation of pirated editions at Leipsic during the fairs; but that is found insufficient to rotect authors whose productions combine excellence vith popularity. The average number of works published f late years at Leipsic has been about six thousand, mounting to about ten thousand volumes, which proably is more than all the other presses of Europe deliver. The press in Germany is nearly free; for though in some states there is a previous censorship, yet it is conducted on liberal principles, and is seldom exercised except on small political works which display more heat than light, or on the class of periodical publications of less than twelve sheets.

No other part of Europe enjoys advantages for education equal to Germany, especially the northern parts of it. The parochial schools are so universal, that none but the wilfully ignorant, or those of imperfect faculties, can be strangers to reading, writing, and the first rules of arithmetic. The schools for classical instruction, denominated *Gymnasiums*, *Pedagogiums*, and *Lyceums*, are found in almost every large town, and dispense learning at a very cheap rate. The universities are sufficiently numerous and sufficiently endowed to provide instruction in the higher branches of knowledge upon terms nearly if not altogether gratuitous.

The number of students in 1831, *communibus annis*, at each of the universities, is as under:—

Universities.	When Founded.	Religion.	Number of Professors.	Number of Students.
Heidelburg..	1346	Protestant.	45	1018
Prague......	1348	Catholic...	41	1449
Vienna......	1361	Catholic...	79	1954
Würtzburg..	1403	Catholic...	36	521
Leipsic......	1409	Protestant.	41	1360
Landshut...	1410, 1810	Catholic...	48	720
Rostock......	1419	Protestant.	34	110
Freyberg....	1456	Catholic...	32	627
Tübingen...	1477	Mixed......	44	887

Berlin........	1808	Protestant.	58	1937
Bonn.........	1818	Mixed......	—	988

Besides these universities, there are in almost all the capitals of every state institutions for instructing pupils in the various learning of the medical, clerical, legal, and military professions, and of agriculture, mining, and the management of forest lands. There are also abundance of learned societies spread over the whole of Germany, many of which have, in the course of years, been enabled to assemble such large collections of natural and artificial curiosities as afford valuable assistance to those engaged in the pursuit of knowledge.

The public libraries collected in the different cities far exceed any thing that has been known in other countries. These valuable collections are managed with the greatest liberality; all of them are open for inspection and perusal at all proper seasons; and from most of them the readers may be supplied at their own residences. They thus become active and efficient fountains of knowledge. It would be tiresome to give a list which should comprehend all those the number of volumes in which exceed 10,000; but we shall present one of those whose volumes are not less than 50,000: viz. Vienna, 550,000 volumes, including manuscripts and local and temporary works; Munich, 400,000 volumes in the royal central library; Göttingen, 280,000 volumes, including some thousand valuable manuscripts; Dresden, 250,000 printed volumes, and 104,000 manuscripts and smaller works; Wolfenbuttel, 190,000 printed volumes, 44,000 manuscripts, and 6000 Bibles;

Stutgardt, 170,000 volumes, besides 12,000 Bibles of all languages and editions; Berlin, 300,000 volumes, in seven public libraries; Weimar, 110,000 volumes, and 20,000 smaller works; Prague, 110,000 volumes; Frankfort, 100,000 volumes, in several public libraries; Hamburg and Breslau have 100,000 each in their public libraries; Mentz, 90,000; Darmstadt, 85,000; Cassel, 70,000; Gratz, 70,000; Gotha, 60,000; Marburg, 55,000; Jena, 50,000. The number of books in all Germany, in such libraries and other institutions as are open to the public, has been estimated at 5,000,000 volumes.

The collections of pictures and of antiquities correspond in extent and in excellence to the public libraries. The gallery of Dresden, now that the pictures which were plundered by France have been sent back from the Louvre to the places whence they had been taken, is the first in Europe. The collections at Berlin, Brunswick, Cassel, and Augsburg, are also very fine; and many private assemblages of pictures, particularly those of the Princes Liechtenstein, Kaunitz, Esterhazy, and Count Schönbrun, are of the very first class. The antique cabinets of Dresden, Munich, and Cassel, are filled with curiosities from remote ages and distant nations; and the cabinets of natural history at Vienna, Berlin, Dresden, Cassel, Manheim, Jena, Munich, and Gotha, are most richly filled.

The greater part of the land in Germany is held by those ancient feudal tenures which formerly prevailed in every part of Europe. The possessors of the soil, of whom in every state the sovereign is by far the greatest, have under them a species of customary tenants called subjects (Unterthäner), who have the cultivation of common fields divided into small portions, without the intervention of fences. As soon as the corn is removed from the field, the lord has the right of pasture; and owing to these circumstances it is impossible to deviate from an ancient practice, by which the different portions of the common land must be devoted to particular kinds of crops at specific periods. The rotation almost universally prescribed, and known by the name of *drey feld landwirthshaft*, consists of a fallow, succeeded by two crops of grain. The fallow, however, generally bears a crop, which is usually either flax, peas, or, very commonly of late, potatoes; in consequence of a crop on the fallow, the land is seldom properly cleaned of weeds. To this fallow crop generally succeeds winter corn, either wheat or rye; but, in the north, the proportion of the latter to the former is as four to one, and in many parts, especially in Pomerania, ten to one. In the southern states, the two kinds of grain are nearly equally cultivated. To the winter corn succeeds barley or oats, as the land is better adapted for the one or the other, or as may have been settled between the ancestors of the present lords and their tenants in remote periods. By this mode of cultivation, the earth yields but a small increase. The tenants can keep but little live stock, and therefore make but little manure. The live stock they do keep is generally fed throughout the winter with straw, and the addition recently of potatoes, with a small portion of corn; and what dung they do produce is consequently of a very weak quality. These tenants are commonly holders of small portions of land, which, in many instances, is necessarily divided at their decease among all their children; and thus the evil of the cottage system of small farms is clearly experienced. The villages are crowded with little proprietors, who have not either the conventional or the pecuniary power to improve the soil, who live in a state inferior to labourers, and who, from the smallness of their farms, can only obtain subsistence by living on the cheapest diet, which of late, as in Ireland, is principally potatoes. Upon this system, the number of husbandmen increases with considerable rapidity; they form soldiers, and when called out by the military conscriptions of their princes, are placed in a better situation than when living on their farms.

In this condition of the community, the only land which can be well cultivated is the small portion of demesne which is in the hands of the lords, who, from their stock of cattle, could make manure to dress and improve the soil. These demesne lands are, however, though cultivated for the lords, ploughed by the tenants, who are bound by their tenures to do certain stipulated work for their superiors. The consequence of this is, that the work is badly performed, and at such seasons as best suits the tenant's own labour. The demesnes, too, feel the want of capital; for the lords have little besides their estates and the cattle upon them, and these being too generally left to the care of managers, who are less thrifty than as proprietors they would be, suffer considerably from that circumstance.

The foregoing sketch is a description of the practice on the far greater portion of the land in Germany; and, in consequence of it, the soil, though superior in original fecundity to the greater part of England, is gradually deteriorating, and does not at present yield more than five eighths of what we raise upon the same quantity of land. From the poorer classes eating nothing but rye or potatoes, and from having three fourths of its population employed in agriculture, Germany is enabled to export corn in most years; but when an unpropitious season occurs the distress is dreadful, and is increased by the smallness of the different states, and the power being restricted of circulating grain freely from one to another; an evil which was severely felt and lamentably deplored in the calamitous year 1817.

The land of Germany produces but little beyond the absolute and indispensable wants of its inhabitants, except in wine, flax, and wool. The culture of the vine is much less attended to than in France; and wine is the production of but a very small portion when compared with the whole extent of the country, whereas in France almost every part yields it. The quantity made in Germany is not calculated at more than about one sixth of what France supplies; the whole is computed to be nearly two million pipes of one hundred gallons each; but a very small part of this finds its way to foreign countries.

The flax frequently forming, as before stated, the fallow crop, is important from the employment it affords, during the long and cold nights of their severe winter, to the female members of the peasants' families, and from the trade it creates in the export of its productions in the form of yarn or of linen cloth.

Wool is generally the property of the lord, and its annual clip is frequently the principal revenue derived from extensive possessions. This has induced many to pay great attention to the improvement of the wool, and much of it, especially from Saxony, is superior to any that the Merino flocks of Spain afford. It is within the few years which have elapsed since the expulsion of the French, that the great extension of the breed of fine-woolled sheep has taken place. The implements of husbandry are in a very imperfect state, and as much so from want of information as from want of capital in Germany. The ploughs are generally small, light, and without a due curvature in the mould-board. The harrows are frequently of wood. That useful implement the roller is rarely seen; the waggons and carts are badly constructed, and the harness of all consists either of ropes or twisted straw.

There are exceptions to these observations on the agriculture of Germany, but they are too few to merit any particular notice.

Germany is generally a manufacturing country, and can supply itself with by far the greater part of all the commodities which it needs. The manufacturers of that coun-ry are not placed in different districts, but in the same owns; and in almost every town of a moderate populaion, woollen, linen, cotton, silk, and iron wares are made. hus their establishments are mostly upon a small scale, nd they cannot avail themselves of those minute divisions f labour which are essential to the perfecting and to the heapness of the goods. Linens are the most valuable rticle, and are made, from the coarse ones of Westphalia, hich are used for negro clothing, to the finest shirting nd table linen of Silesia and Saxony, and of all the interediate qualities. Woollens of all kinds are made, and are fficient for the consumption, so that those of England nd France are scarcely needed; nor do the Germans alw that any foreign fine linen cloth is equal, either in uality or price, to those manufactured in Saxony, Silesia, nd the newly acquired Prussian provinces on the Rhine, om wool of native growth. The cassimeres and Vigoia cloths, in that last-mentioned district in the towns of upen, Machren, and Aachen, are preferred to any which re brought from other countries. The fabrics of cotton ad much increased during the continental system of exlusion, and had arrived at a considerable degree of perection; but the return of tranquillity has checked the proress of all, and annihilated many. The most considerble districts for these kinds of goods are the kingdom of axony, the Prussian provinces of Juliers, Berg, and leves, and on the banks of the Ens, in the Austrian doinions. The silk manufactures have never been conderable; some goods of the kind are made in many of he cities, but the principal establishments are in Vienna, t Roveredo in the Tyrol, at Creveldt, at Cologne, and at erlin. Leather, iron, steel, and the wares prepared from hem, are made at home. Porcelain and common earthenare are well made, and the two great royal manufactoies of the first at Berlin and Dresden equal any from èvre, from Worcester, or Etruria. The glassware of Boemia, though of a very bad quality, is universally diffusd, not only throughout Germany, but in most other parts f the world. Paper is a considerable article amongst the erman manufactories. That for printing is coarse, and f a bad colour, and the writing paper is very imperfecty made. There are 506 mills, which deliver annually bout 60,000 bales, but none of it goes to other countries. hemical preparations are made upon an extensive scale, nd comprehend alum, vitriol, smalts, white lead, Prusian blue, sal ammoniac, and verdigris. Salt and sugar re refined for home consumption. Tobacco, snuff, wax, nd oils from plants, are also supplied from domestic manuctories. The quantity of beer furnished by the breweries n every town in the north is very great, and the distilleies of ardent spirits from grain form a most extensive maufactory; vinegar is mostly prepared from grapes in those istricts where they do not ripen sufficiently to be made nto wine. The minuter articles, such as musical, matheatical, surgical, and optical instruments, with watches nd clocks, are well and cheaply made. Wooden toys nd plaited straw are important objects of employment to any of the inhabitants. Most of the fabrics of Germany re fettered by the laws of the guilds, or corporations, to hich the masters are obliged to belong; and this acts as n impediment to their arriving at a high degree of perection.

The commerce of Germany, conducted by means of hipping, centres principally in the Prussian ports, or in he free cities, and may be best treated of under each of hem. The commerce with France, Italy, Turkey, Poand, and Russia, is by no means great. The articles prouced on the borders of each are too similar to cause a ecessity for an interchange; and the heavier articles, hich are produced at a distance from the respective bounaries, will, in few instances, bear the expense of land carriage. The trade which is purely internal, or amongst the different states, is much less than might be expected, and much less than it would be if there existed less of a monopolizing spirit among the cities, and less of jealousy among the several sovereigns. The greater part of the internal trade consists in the sale of wines, and of foreign colonial produce, which the capitalists in the cities collect and sell in smaller quantities to the shops' in the provincial towns.

As the other independent states of Germany are separately described in this work, and Baden only referred to Germany, in the alphabetical order, the following is a more especial notice of it.

It is a grand duchy, is bounded on the north-east by Bavaria, on the east by Wurtemberg and Hohenzollern, on the south-east by the lake of Constance, on the south by Switzerland, and on the west and north-west by France. It extends over 6008 square miles, and has been recently divided into four circles, thus:

Circles.	Extent in Square Miles.	Population.	Capitals.
The Lake...........	1184	169,749	Constance.
Upper Rhine........	1507	318,540	Freyburg.
Middle Rhine......	1958	397,805	Rastadt.
Lower Rhine........	1359	301,846	Manheim.
	6008	1,187,940	

The face of the country is peculiarly striking. On the western side a most fertile stripe of land is bounded by the river Rhine, from which rises that mass of mountains on the east known as the Black Forest, one of the peaks of which is of the height of 4600 feet. In the valleys the husbandry is good and productive, and the crops of hemp, madder, tobacco, poppies, beans, and potatoes, are most luxuriant. Even in the mountainous parts, rye, wheat, and oats are extensively cultivated, but much of the surface is covered with woods. A considerable extent of pasture land supplies the duchy with good butter, meal, and some cheese. The vineyards are extensive, occupying one tenth of the country, and producing various kinds of excellent wine; and the gardens and orchards supply abundance of fruits of the best description, and especially almonds, chestnuts, and walnuts, at very cheap rates. Though not more than half the land is cultivated, the supply of every agricultural product is more than sufficient for the inhabitants.

The mining concerns are numerous but not large, and yield commonly 5000 ounces of silver, 400 quintals of copper, 2000 of lead, 320 of cobalt, and iron to the extent of 1000 tons. The mineral springs are numerous, but those of the greatest celebrity in the duchy of Baden are almost exclusively resorted to by visitors for health or pleasure.

Baden is a manufacturing country for many articles, the value of which arises almost wholly from the labour employed in their preparation. In some years 110,000 wooden clocks and 50,000 dozen of wooden spoons are made. These are only a part of the numerous smaller kinds of ware which the ingenuity of the inhabitants prepares. Besides these, there are manufactures of linen and woollen goods produced, but of the coarser sorts.

The reigning house has risen to its present dignity and consideration since the peace of Luneville in 1801, when its territory extended only over 1554 square miles, inhabited by 210,000 people. By the treaty then made, the dominions were nearly doubled, and further augmented by the treaty of

Presburg in 1803; and by some smaller additions at subsequent periods, it has attained its present extent. A constitution has been given by the prince, by which an upper and a lower house of legislators is established. The revenues amount to about L.1,000,000 annually; and the expenditure, including a sinking fund for the discharge of the public debt, is about equal to it. Since the general peace, the debt has been gradually diminished, from L.2,000,000 to its present amount, which in 1832 was L.1,300,000. The regular army consists of 8000 infantry, 1500 cavalry, and 850 artillery. The contingent to the German confederation is fixed at 10,000 men. The three religions are equally established, but the prince adheres to the Lutheran church. The Catholics are the most numerous body, being about 800,000. The Lutherans and Calvinists have united since 1821, and amount to 365,000; and there are nearly 20,000 Jews. There are two universities, that of Heidelburg for the Protestants, the oldest in Germany, and that at Freyburg for the Catholics. The principal cities and their population are as follows:

Manheim	22,000	Pforzheim	6,400
Carlsruhe	20,000	Lahr	6,000
Freyburg	15,000	Constance	5,700
Heidelburg	12,500	Rastadt	5,700
Bruchsal	7,000		

(G.)

GERMEN, the seed-bud, defined by Linnæus to be the base of the pistillum, which contains the rudiments of the seed, and, in progress of vegetation, swells and becomes the seed-vessel. In assimilating the vegetable and animal kingdoms, Linnæus denominates the seed-bud the *ovarium* or *uterus* of plants; and affirms that it exists chiefly at the time of the dispersion of the male dust by the antheræ, since, after its impregnation, it becomes a seed-vessel. Germen, by Pliny and the ancient botanists, is used to signify a bud containing the rudiments of the leaves.

GERMINATION, amongst botanists, comprehends the precise time which the seeds take to rise after they have been committed to the soil. The different species of seeds are longer or shorter in rising according to the degree of heat which is proper to each. Millet, wheat, and several of the grasses, rise in one day; blite, spinach, beans, mustard, kidney beans, turnips, and rocket, in three days; lettuce and dill, in four; cucumber, gourd, melon, and cress, in five; radish and beet, in six; barley, in seven; orach, in eight; purslain, in nine; cabbage, in ten; hyssop, in thirty; parsley, in forty or fifty days; peach, almond, walnut, chestnut, peony, horned poppy, hypecoum, and ranunculus falcatus, in one year; rose bush, cornel tree, hawthorn, medlar, and hazel nut, in two. The seeds of some species of orchis, and of some liliaceous plants, never rise at all. Of seeds, some require to be sown almost as soon as they are ripe, otherwise they will not sprout or germinate; and of this kind are the seeds of coffee and fraxinella. Others, particularly those of the pea-bloom flowers, preserve their germinating faculty for a series of years.

GERONA, a city of Spain, in the province of Catalonia. It is situated on the river Ter, at its confluence with the Oña, and is a strongly fortified city, of great celebrity in the military history of Catalonia, by the sieges it has sustained at various periods. None of the resistances it has made, or indeed of those made by any other city, surpasses the obstinate defence which it sustained against the armies of France during the late war. It is the see of a bishop, and has a magnificent cathedral, with many other substantial public buildings. The diocese of Gerona was one of the best cultivated and most flourishing districts of Spain. The portion of it on the sea coast abounds in wheat, wines, and vinegar; the sides of the mountains are covered with vineyards and olive gardens, and the tops yield the best oaks and other useful trees. The ravages of war have been very severely felt; but the fertility of the soil, and the industry of the inhabitants, will, it is hoped, speedily repair the injuries it has endured. Its inhabitants amount to 14,000. It is in north latitude 42. 0. 2.

GERONTES, in *Antiquity*, a kind of judges, or magistrates, in ancient Sparta, answering to what the Areopagites were at Athens. The word is Greek, γερων, and signifies an old man, whence also the words *gerontic*, something belonging to an old man; and *Geronicon*, a famous book amongst the modern Greeks, containing the lives of the ancient monks. The senate of Gerontes was called *Gerusia*, that is, an assembly or council of old men. The Gerontes were originally instituted by Lycurgus; and their number, according to some, was twenty-eight, but according to others, thirty-two. They governed in conjunction with the king, whose authority they were intended to balance, and also to watch over the interests of the people. Polybius defines their office in few words, when he says, *per ipsos, et cum ipsis, omnia administrari.* None were to be admitted into this office under sixty years of age, and they held it for life. The Gerontes were succeeded by the Ephori.

GERS, a department in the south-west of France, formed out of Condomois, Armagnac, and Comminges, portions of ancient Gascony. It is bounded on the north by the department of the Landes and of Lot-Garonne, on the east by Tarn-Garonne and Upper Garonne, on the south by Upper Garonne, Upper Pyrenees, and Lower Pyrenees, and on the west by the Landes.

The extent is 2717 square miles, or, according to the Royal Almanack, 623,719 hectares. It is divided into five arrondissements, twenty-nine cantons, and 685 communes, which are inhabited by 312,160 persons. The whole surface of the department is covered with hills, between which are some pleasant valleys, but no plains; but none of those hills exceed 1200 feet in height, and they are a kind of spurs or projections from the mass of the Pyrenees. The soil is generally clayey, but intermixed with stripes of calcareous and sandy land. The melting of the snows on the Pyrenees in the months of May and June causes great injury to the land, before it passes by the beds of the various rivers and rivulets which empty themselves into the Adour. The inhabitants are a lively, cheerful race, simple in their dress, food, and houses, and speak the Gascon language, which is a mixture of Latin, Italian, and Spanish, rich in diphthongs and vowels. Garlic and onions are abundantly cultivated, and form an important portion of the aliment of the inhabitants. Agriculture is in a backward state, and barely produces sufficient corn for the scanty consumption of those who use it. The meadows are about a tenth part of the land, but, from neglect, furnish only a scanty provision for the cattle, which are by no means distinguished for their good qualities. The number of cattle was in 1801 as follows:—11,710 horses, 3020 mules, 171,506 cows, oxen, and calves, 517,380 sheep, and 37,500 pigs. The sheep yield only coarse wool. Fruit is cultivated negligently, and the produce of the vineyards is barely sufficient for the department, and is of bad quality. Brandy is made, and is almost the only article exported; some of it is highly prized. The forests have been wasted, and now scarcely yield sufficient fuel for the inhabitants. There is little manufacturing industry, and no trade with other districts, excepting the export of some brandy, and of a few cows, calves, sheep, and lambs.

GERTOKH, a town of Thibet, and a mart for the exchange of the productions of Nepaul with those of the country. The imports consist of grain, oil, sugar, cottons, chintzes, iron, brass, lead, dates, almonds, peaches, &c.; and from Gertokh are exported for the Cashmerian market, shawl wool, to Nepaul and Hindustan gold dust, silver, musk, scented leather, shawls, China ware, tea, salt, borax, &c.

GERVAISE, or GERVASE, of Tilbury, an historian of the thirteenth century, was a native of Tilbury in Essex, and nephew of Henry II. The exact date of his birth has not been ascertained. Having visited part of Europe, he arrived, about the year 1208, at the court of Otho IV. Emperor of Germany, who, being descended by his mother from an illustrious family in England, received Gervase with the greatest distinction, made him one of his orators, then nominated him chancellor, and, lastly, appointed him marshal of the kingdom of Arles. Gervase died about the year 1218. His productions are, 1. Otia Imperialia, libri tres, a work which is also known under the titles Mappa sive Descriptio Mundi, and De Mirabilibus Orbis; 2. Illustrationes Galfridi Monemuthensis, libri iv.; 3. Historia Terræ Sanctæ; 4. De Origine Burgundiorum; 5. Facetiarum liber, dedicated to Henry II. of England; 6. Tricolumnium Angliæ; and, 7. Metrica Descriptio Balneorum Puteolanorum. The compilation of the Exchequer book, entitled *Liber Niger Saccarii*, was ascribed to Gervase; but Madox, who published a correct edition of this Black Book, attributes it to Richard Nelson, bishop of London. There are two manuscript copies of this work; one in the Exchequer, presented, according to Strype, by Archbishop Parker; and another in Caius College, Cambridge, which is supposed to have been the original, whence the archbishop's copy was transcribed. Bale and Pitts differ considerably in their accounts of Gervase's works, the greater part of which still remain in manuscript, and are but little known.

GERUND, in *Grammar*, a verbal noun of the neuter gender, partaking of the nature of a participle, but declinable only in the singular number, through all the cases except the vocative. The word is formed from the Latin *gerundivus*, and that from the verb *gerere*, to bear. The *gerund* expresses not only the *time*, but also the *manner* of an action; as, he fell in running post. It differs from the participle in this, that it expresses the *time*, which the participle does not; and from the tense properly so called, in expressing the *manner*, which the tense does not. See GRAMMAR.

GESA, a city of the grand duchy of Saxe Weimar, in Germany, in the principality of Eisenach. It is situated on the river Ulsten, and contains 304 houses, with 1890 inhabitants. It is the capital of a bailiwick of the same name, formerly a part of Fulda, containing 6410 inhabitants.

GESNER, CONRAD, a celebrated naturalist, surnamed the Pliny of Germany, and, for his time, a prodigy of application, knowledge, and sagacity, was born at Zurich on the 26th March 1516. He was the son of Vasa Gesner, furrier, and Barbara Frick, persons who, besides being poor, had several other children, so that he would not have been able to continue his studies had it not been for the assistance of his maternal uncle John Frick, a minister, who formed his taste for letters, and gave him his first notions in botany. But this uncle having died, and his father having been killed in 1531, at the battle of Zug, where the celebrated reformer Zwinglius also perished, young Gesner found himself obliged to seek his fortune in a foreign country. He accordingly went to Strasburg, where, by means of a salary, he for some time seconded the labours of Capiton; then, having obtained some assistance from the canons of Zurich, he repaired to Bourges, and there commenced the study of medicine. At the age of eighteen, having occasion to visit Paris, he indulged without rule and without restraint his passion for all kinds of study, being assisted in his poverty by John Steiger, a young Bernese of patrician family, with whom he was connected by the ties of friendship. From Paris he returned a second time to Strasburg, whence, in 1536, he was recalled to Zurich to occupy in the college of that place the petty employment of regent. But the magistrates having soon perceived that he was formed for less obscure and more important labours, made him, in 1537, a new grant, to enable him to continue his medical studies at Bâle; and it was in this latter city that he began to labour for the public by superintending an edition of the Greek Dictionary of Favorinus. The following year, the senate of Berne having founded an academy at Lausanne, Gesner was appointed to that institution, and taught Greek there for three years. He then passed a year at Montpellier, where he became intimately connected with the celebrated physician Laurent Joubert, and the great naturalist Rondelet. At length, in 1541, he was received as doctor in medicine at Bâle, where he completed some extracts from the Greek and Arabian authors on botany and medicine, which were published the same year at Zurich and the succeeding one at Lyons. Soon afterwards, he published a Catalogue of Plants in four languages, in which he gave proofs of very extensive knowledge in botany, and indicated several vegetables which were then new. Some journeys in the Alps of Switzerland and Savoy enabled him to discover other plants which were also new, and led him, in 1542, to write a little book on milk, accompanied by a letter on the beauty of the mountain scenery. The same year he translated from the Greek a Treatise on Syllogisms, and other philosophical works, which were followed in 1543 by the Maxims of Stobæus, and in 1544 by the Allegories of Heraclides of Pontus, the Discourse of Dion Chyrsostom on Homer, and a purified edition of Martial. In 1545, he made a journey to Venice and to Augsburg, where he formed an acquaintance with several men of merit, and had an opportunity of consulting many rare works and valuable manuscripts. It was then that he began to bring out his famous *Bibliothèque Universelle*, the first great bibliographical work which the moderns had produced. The titles of all the works then known in Hebrew, in Greek, and in Latin, whether extant or lost, and often a summary of their contents, with a judgment of their merits, and some specimens of their style, formed the substance of this collection. The first volume, published at Zurich in 1545, is classed in the alphabetical order of the names of the authors; the second, which is arranged in the order of the materials, and divided into nineteen books, appeared at the same place in 1548, under the title of ***Pandects;*** the twenty-first book, devoted to theology, was published the following year; but the twentieth, which was to treat of works on medicine, has not been printed, because the author did not conceive it so complete as it ought to be, or as the subject required. The Library of Gesner has been abridged by Lycosthenes, and completed by Simler and by Fries, Zurich, 1583, in folio. During the same time, he occupied himself with editions or translations of different small Greek treatises; in particular, he published a corrected edition of Hermolaus Barbaro, a critical Preface on the works of Galen, another on the History of Plants by Tragus, a Treatise on the Mineral Waters of Switzerland and Germany, and a Description of Mount Pilat near Lucerne. But, amidst these diversified labours, he lost no opportunity of collecting and arranging materials for a great work on Natural History, of which he had conceived the plan from his earliest youth. Numerous friends whom his merit had procured him in almost all Europe, sent him figures and notices of the productions of their various climates, and sometimes the natural objects themselves, which he caused to be painted and engraved. As often as he had leisure, he also travelled in Switzerland and in Germany. He had long desired to visit the coasts of the North Sea, but the religious war which broke out in 1551 constrained him to return home without having accomplished the object of his wishes. Gesner has written on the three kingdoms of nature, but his History of Animals is the most considerable of his works on natural history, and that which will ensure him the most durable reputation. It is divided into five books, which are commonly bound in three volumes folio. The first book, printed originally at Zurich in 1551, treats of viviparous quadrupeds; the second, printed in 1554, of oviparous quadrupeds; the third, printed in 1555, of birds; the fourth, printed in 1556, of fishes and other aquatic animals; and the fifth, a posthumous publication, which appeared at Zurich in the year 1587, of serpents. There was to have been a sixth book on insects, but it is doubtful whether Gesner had commenced preparing it, and all that remains consists of some inedited figures of butterflies. Besides these first editions of the different parts of the History of Animals, there appeared several others, some of which, considerably amplified, were printed during the author's lifetime, or after his death, in Latin, German, and French, and also various abridgments under the titles of *Icones Animalium*, *Icones Avium*, *Nomenclator Aquatilium*, &c. In this great work, the author arranges animals in the alphabetical order of their Latin names, and gives details respecting each, divided into eight heads, viz. its denominations in the different languages, ancient and modern; its description, internal as well as external, and the countries it inhabits; the duration of its life and of its growth, with the epoch of its fecundation and birth, and the number produced at a birth; the maladies to which it is subject; its peculiar habits and instincts; its utility; the aliments on which it subsists; the remedies which it supplies; and, lastly, the images which it furnishes to poetry and eloquence, as well as the epithets which have been applied to it. In a word, every thing which the ancient authors, or those of the middle age, have written relative to these details, is introduced under one or other of the heads which we have enumerated; and Gesner also adds, with as much critical sagacity as could be employed in an age when the authority of the ancients was still greatly respected and nature very little known, a vast number of new details derived from his own observations, or communicated by his numerous correspondents. He states many exact facts, which are still deserving of attention, particularly respecting the animals of Switzerland; each species is represented by a figure in wood; and those which the author had caused to be copied from nature are very exactly given; but he was also obliged to borrow some of them from his predecessors, and these are not always remarkable for the same degree of accuracy. The history of fishes, however, is not given altogether on the same plan as that of the others; for here Gesner copies, on each species, the articles of his two friends and contemporaries, Belon and Rondelet, to which he has merely made some additions. As the abridgments appeared after the large treatises, they contain several remarks which are not to be found in the latter; and it is necessary to consult both in order to obtain a complete idea of what was then known on the subject. The History of Animals by Gesner may therefore be considered as the basis of all modern zoology. Copied almost literally by Aldrovand, and abridged by Johnston, it has served as the foundation of works much more recent; and more than one celebrated author has borrowed from it, without acknowledgment, nearly all his erudition; for it is deserving of remark, that the passages in the ancient authors which escaped Gesner have scarcely at all been taken into consideration by the moderns. By his accuracy, his clearness, his good faith, and even in some instances the refinement of his views, Gesner merited this confidence; and although he may not have established genera nor natural classification, yet, in various places, he indicates with tolerable distinctness the true relations of beings. Another important service rendered by Gesner to zoology consists in his edition of a complete translation of the works of Ælian, which he published in 1556, immediately after his volume on fishes. His new notes on the text, which had long occupied his attention, appeared for the first time in the edition published by A. Gronovius, London, 1744, two vols. in folio, as those on the *Historiæ Diversæ* did in the edition of Leyden, 1731, in 4to. Although he has been less fortunate in the publication of his labours on botany, he has perhaps rendered himself even more celebrated in that science by the fecundity of the views which he has introduced into it; for not only was he from his infancy addicted to the collection of plants, and accustomed to rear them, but he soon learned to delineate them, and, in fact, painted more than fifteen hundred, the figures of which he intended for a general history of vegetables. This exercise led him to direct his attention to the numerous details of the flower and the fruit; and he thus succeeded in discovering the art of distinguishing and classing plants by the organs of fructification, an art which has truly created botanical science. In the text he expresses clearly the necessity of attending to characters of this kind in botany. It is to be observed, however, that his *Enchiridion Historiæ Plantarum*, printed at Paris in 1541, is not deserving of much attention; it is a youthful performance of Gesner, and is merely a compilation. His real botanical works, after having passed in manuscript into different libraries, were, about the middle of the last century, acquired by Trew, a botanist of Nuremberg, and published by Schmiedel, physician to the margrave of Anspach, Nuremberg, 1754 and 1770. They consist of Commentaries on the fifth book of Valerius Cordus, Fragments of a History of Plants, commenced according to the plan of Gesner, by Wolf, his pupil, and a great number of figures which he had designed, with the relative notes and descriptions. The little treatise of Gesner on the figures of fossils, stones, and gems, Zurich, 1565, in 8vo, attracted attention to the subject of petrifactions and crystals; and we find from his letters, that he had made experiments on several minerals, and was not ignorant of the electrical qualities of certain precious stones. Lastly, in his *Mithridates de differentiis Linguarum*, Gesner, not confining himself to the comparison of different languages, threw out several very ingenious ideas respecting language generally, which have since been more fully developed. His own acquisitions as a linguist were in fact very considerable. He possessed a knowledge of the three learned languages, had some tincture of Arabic, understood French, Italian, and Flemish, and had laboured much to improve the German language. So many useful works having secured to Gesner merited consideration, the magistrates of Zurich, in the year 1555, created him public professor of natural history. The Emperor Ferdinand I., who loved the sciences, and to whom Gesner had dedicated his History of Fishes, invited him to Augsburg in 1559, and in 1564 granted him a coat of arms emblematic of his pursuits, and at the same time sent him some fragments of bezoar, a substance which was then regarded as exceedingly precious. But he did not long enjoy these marks of esteem. A pestilential malady, which had commenced at Bâle in the spring of 1564, and extended itself to Zurich, where it re-appeared the following year with great fury, at length smote Gesner. During these two years e had bestowed great care on the persons who were afected with this disease, and had even written a dissertaion on the best method of treating it ; but a bubo having howed itself under his right armpit, although it occaioned him but little pain, he considered himself as doomd to fall a victim to the prevailing malady ; and, accordngly, having caused himself to be carried into his cabinet, hat he might put his works in order, he died there, while hus occupied, on the 13th of December 1565, aged only orty-nine years and some months. He bequeathed his brary and his manuscripts to Gaspar Wolf, his pupil, hom he charged to publish all that could be extracted om his papers calculated to advance any branch of the atural sciences. *(Eloges de M. de Thou ; Mémoires de Vicéron ; Biographie Universelle).* (A.)

GESNER, *Solomon*, author of the death of Abel, and any other works in the German language, was born at urich in the year 1730. In his early age he showed few gns of superior abilities ; and his progress in the rudients of education was so slow, that his master gave him p as incapable of any greater attainments than writing d the four elementary rules of arithmetic. He was en placed under the care of a clergyman in the neighourhood, a relation of his father's, who showed himself etter acquainted with the art of discovering the natural clinations of his pupils. This gentleman often carried oung Gesner with him into the fields, where he made him bserve the beauties of nature ; and finding that he took reat pleasure in such lessons, and seemed to listen to em with peculiar attention, he occasionally repeated me of the most striking passages of the ancient authors, ho have written on these subjects in the most agreeable d pleasing manner. By this ingenious artifice, the mind f young Gesner began to open, and its powers to expand ; d it is perhaps owing to this circumstance that he beamo so fond of the language of Virgil and of Theocritus. Vhen he arrived at a proper age to think of following me pursuit or business, Gesner made choice of that of ookseller, which was the profession of his father, and in me measure of his family. Of five houses at Zurich enaged in the printing and bookselling business, two were ccupied by Gesners ; one belonged to two brothers of at name ; and the other, that in which our poet had a hare, was known by the denomination of Orel, Gesner, d Company. It was known also by the extent of its orrespondence, and by the choice and elegance of the orks which it gave to the public.

Though Gesner was a bookseller, he did not, however, amp his genius by submitting to the drudgery of busiess. He indulged himself freely in pursuing his favoure object, and his partners never envied him that time hich he devoted to meditation and study. In 1752, he ade a tour through Germany, not so much for the purose of extending his commerce, as to see and become acuainted with those authors who had done honour to their ountry. The following circumstance, which occurred duing this tour, deserves to be mentioned, as it is strikingy characteristic of the timidity which often accompanies rue genius. When Gesner was at Berlin, he was admited into a literary society, of which Gleim and Lessing vere members. Each of the authors who composed it sed to read in turn some pieces of their own composiion, and Gesner felt desirous of submitting to these able ritics a small work, which was his first attempt ; but he vas far from resembling those poets whom Horace and ther satirists have ridiculed, and who stun every one they neet by reciting their verses. As each of the members ad done reading, Gesner was observed to move his hand vith a kind of tremor towards his pocket, and to draw it ack again without bringing out the manuscript which he ught to have produced. Having not as yet published any thing, none of the company could guess the cause of a motion which his modesty prevented him from explaining. The work which he had not the courage to show was his small poem entitled Night, which he published on his return to Zurich in 1753. It was considered as an original, of which no model is to be found among the moderns ; but in the opinion of the author, it was only a piece of imaginary painting, or, to use an expression of his own, in one of his letters to Huber, who has translated his works, " a caricature composed in the moments of folly or intoxication." In this little poem he has introduced a short episode on the origin of the glow-worm, containing a poetical explanation of this natural phosphorus, which has all the beauty of Ovid's Metamorphoses, without their prolixity. The success of this essay emboldened the too timid muse of our young bookseller, and he published a pastoral romance called Daphnis, in three cantos. The applause which was deservedly bestowed upon this performance induced the author to publish, some time after, his Idylls and other rural poems, in imitation of those of Theocritus. Pastoral poetry, which at this time was little known in Germany except by translations from foreign poets, began to find many partisans, and to be preferred to every other kind. Desirous, therefore, of tracing out a new path for himself, our poet thought that he could not do a more acceptable service to his countrymen than by painting the felicity and innocence of rural life, and the tender emotions of love and gratitude. The only author worthy of notice who had preceded Gesner in this career was Rost of Leipsic, whose pastoral poems appeared for the first time in 1744. This writer polished the language of the German shepherds ; and he had address enough to unite spirit and simplicity in a kind of writing which is insipid without the one, and which becomes unnatural and disgusting if it want the other. He sometimes throws a delicate veil over those images which are deficient in decency, but it is to be regretted that it is often much too light. Such was the antagonist against whom Gesner had to contend. Our poet, however, pursued a different course. Instead of placing, like Rost, his scenes in modern times, he goes back, with Theocritus, to that happy age which we are fond of reviewing when our passions are calm, and when, freed from those anxious cares which hurry us beyond ourselves, we contemplate amidst tranquillity the beauty and fertility of nature. The characters of Gesner's Idylls, therefore, are taken from those societies which exist no longer except in the remembrance, or rather the imagination. His shepherds are fathers, children, and husbands, who blush not at these titles so dear to nature, and to whom generosity, beneficence, and respect for the Deity, are sentiments no less familiar than love. These Idylls were the principal and favourite object of his pursuit, and that part of his works which acquired him the greatest reputation, especially amongst his countrymen. His Death of Abel, which is well known, was published for the first time in the year 1758. It is written, like the rest of his pieces, in poetical prose, and was so much sought after, that it went through no less than three editions in the space of a year, without speaking of the spurious ones which appeared in Holland, at Berlin, and in France. The French edition was followed by several others. One came out in Italian ; another in the Dutch language ; another in the Danish ; and, lastly, two in English, one of them in prose and the other in verse. Amongst the pieces which Gesner published after the Death of Abel was his First Navigator, a poem in three cantos, which many people in Germany consider as his masterpiece. He made an attempt also in the pastoral drama, but not with the same success as in other kinds of rural poetry. He produced likewise, in the same style, Evander and Alcimne, in three acts ; and Erastus, a small piece of one act, which was represented with some applause in several societies, both at Leipsic and Vienna.

But though poetry was Gesner's darling pursuit, and though he enriched the literature of his country with works which will render his name immortal, he did not confine himself to one manner of imitating nature; he in turns took up the pencil and the pen, and his active genius equally directed both. In his infancy he had received a few lessons in drawing, and he had afterwards pursued this study, but without any intention of becoming an artist. At the age of thirty he felt that violent desire which may be considered as the voice of genius; and this was in some measure excited by the sight of a beautiful collection formed by Heidegger, whose daughter he had married. To please his father-in-law, he studied this treasure, composed principally of the best pieces of the Flemish school; and to this new taste he had almost sacrificed every other. Gesner at first ventured only to delineate some decorations for the frontispieces of curious books printed in his office; but by degrees he acquired the courage to make other attempts. In 1765, he published ten landscapes etched and engraved by himself, and dedicated them to his friend Watlet. Gesner owed him this mark of respect for the care which he had taken to ornament with beautiful vignettes Hnber's translation of his Idylls. Twelve other pieces appeared in 1769; and after these attempts, Gesner executed ornaments for many works which came from his presses, amongst which were his own works, a German translation of Swift, and several other productions.

Were we to judge from Gesner's enthusiasm for his favourite pursuits, and from the time and attention which he bestowed upon them, we should be apt to conclude that he had found but little leisure for discharging his duty as a citizen. The contrary, however, was the case; for he passed almost the half of his life in the first employment of the state. In 1765 he was called to the grand council, and in 1767 to the lesser. In 1768 he was appointed bailiff of Elibach, in 1776 head of the four guards, and in 1781 superintendent of waters, which office was in 1787 continued to him for six years. In all these stations Gesner discharged his duty with the most scrupulous fidelity, and died of a paralytical disorder, lamented by his countrymen and by those who had the pleasure of his acquaintance, on the 2d of March 1788, at the age of fifty-six.

GESTURE, a motion of the body, intended to signify some idea or passion of the mind. It consists principally in the action of the hands and face, and may be defined, a suitable conformity of the motions of the countenance, and of several parts of the body, in speaking, to the subject-matter of the discourse.

GETÆ, the same people who were known to the Romans under the name of Dacians. They were originally a Thracian tribe, occupying the country between Mount Hæmus, the lofty ridge of the Balkan, and the lower part of the river Danube, and distinguished from the rest of their countrymen neither in language nor in manners. Here Herodotus seems to have known them probably from personal observation (iv. 93), and Thucydides speaks of them as occupying the same position (ii. 96). It was not till Philip of Macedon and his successors proceeded to extend their conquests over the Thracian tribes, that we hear of the Getæ changing their abode. When Alexander (about 333 B. C.) made an expedition into their country, he found them on the north side of the Danube, but we have no means of ascertaining whether they still retained their possessions to the south. His successor Lysimachus was not equally successful in his war with the Getæ. Having been taken prisoner by their king, he was asked to observe the poverty of the nation, and at the same time advised not to make war upon a people whose wants were so few and so easily supplied. He was afterwards allowed to depart in safety. (Diod. Sic. *Fragm.* xxi.; Memnon, ap. Phot. cod. 214, c. 6.) In the reign of Perseus, last king of Macedon (170 B. C.), we find the eastern bank of the Danube in possession of the Bastarnæ, a Teutonic people, who must have expelled the Getæ, and gave occasion to the appellation of *Deserta Getarum*, by which it was first known to the Romans. The Getæ seem to have travelled westwards, and settled in Transylvania, spreading themselves over Hungary. Here their power increased so much under one of their kings, Bœribistas, that it became formidable even to the Romans; they pillaged Thrace, and reduced the country of the Boii to a desert. At this time they were in possession of part of the country to the south of the Danube, a part of Servia and Bulgaria, where we find them attacked by the Romans (Justin. xxv. 1.; Flor. iii. 4). At last Augustus determined to subdue them, and he found the attempt less difficult than he had expected, for Bœribistas was dead, and his kingdom divided into several parts. The Roman generals compelled the Getæ partly to submit, and partly to withdraw to the north of the Danube. Mœsia was erected into a province, the banks of the river were studded with fortresses, and the kingdom of the Getæ to the south was put an end to for ever. (Strab. vii. 304, 305.) During the whole of the first century of the Christian era, the Getæ continued to make incursions from their mountains into the Roman territory, but it was not till the reign of Domitian that they became truly formidable. They were then under the command of Decebalus, who directed their proceedings with so much prudence and vigour, that the emperor found himself obliged to conclude with them a disgraceful treaty. The succession of Trajan to the empire, and his well-known experience and wisdom, induced Decebalus to lower his tone; but it was too late, for Trajan was determined to relieve the Romans from all danger in this quarter. Trajan crossed the Danube with a formidable army; and Decebalus, after several unsuccessful battles, found himself obliged either to submit or to put an end to his life. The latter alternative he chose as the more honourable, and his subjects submitted to the conqueror. His kingdom was erected into the province of Dacia, the only one which ever existed to the north of the Danube; and as the land was nearly without inhabitants, Trajan transferred to it many from other parts of the empire, and the province became Roman not only in manners, but even in language (Dion. Cass. lxviii. 14; Eutrop. viii. 2, 6). The Romans were not allowed to remain quietly in possession of this country, but they continued to maintain their footing until the reign of Aurelian (A. D. 271), who, convinced of the impossibility of resisting the encroachments of the Goths without some better protected frontier than Dacia presented, determined to withdraw the Roman inhabitants to the south side of the Danube. The greater number followed his advice, and were placed in the country between Upper and Lower Mœsia, in the present district of Servia and Bulgaria, which was then called Dacia Ripensis (Eutrop. ix. 15; Vopisc. in Aurel. c. 39). The name of Dacian or Getan was no longer heard of; but a considerable number of the people still remained, preserving their ancient customs and the Latin language. There seems indeed to be little doubt that the present inhabitants of Wallachia are descendants from this people, as it is difficult otherwise to account for their language so closely resembling the ancient Latin. (See a discussion on this subject in Thunmann's Untersuchungen über die Geschichte der östlich Europ. Volker, Leips. 1774.)

GETHIN, LADY GRACE, an English lady of uncommon talents, was the daughter of Sir George Norton of Abbot's Leigh, in Somersetshire, and born in the year 1676. She

Ghauts.

hl all the advantages of a liberal education, and became
t wife of Sir Richard Gethin, of Gethin Grott in Ireland.
Se was mistress of great accomplishments, natural and
ajuired, but did not live long enough to display them to
t world, having, unfortunately, died in the twenty-first
yr of her age. She was buried in Westminster Abbey,
vere a beautiful monument with an inscription is erect-
e over her remains; and for perpetuating her memory,
pvision was made that a sermon should be preached in
estminster Abbey yearly, on Ash Wednesday. She
vote, and left behind her, in loose papers, a work, which
sn after her death was methodized, and published under
t title of *Reliquiæ Gethinianæ;* or, some Remains of
ace, Lady Gethin. This was a collection of choice dis-
crses, pleasant apophthegms, and witty sentences, writ-
t by her, for the most part, by way of essay, and at
lsure hours. London, 1700, 4to.

GETHSEMANE, in *Ancient Geography*, a village in
t Mount of Olives, whither Jesus Christ sometimes re-
ted in the night-time. It was in a garden belonging to
ts village that he suffered the agony in which he sweated
ops of blood; and here also he was arrested by Judas,
ad the rest who were conducted by that traitor.

GHASSA, the capital of a district in Bootan, and the
stion of a provincial governor. It is surrounded with
lgh mountains covered with snow throughout the year,
the base of which is a spring of water of so high a tem-
rature as scarcely to admit of bathing.

GHAUTS. The term of Ghaut signifies originally a
ss through the mountains, or the place where boats
nd. But it has been applied to designate the mountain-
s chains which run in a direction nearly north and south
rough southern India. These are divided into the East-
n and Western Ghauts. The eastern ridge commences
the south, to the north of the Cavery, in about latitude
. 20. north, and extends, with little interruption, and
arly in a straight line, to the banks of the Kistnah, in la-
ude 16. north. The height of this ridge has never been
curately ascertained throughout its whole extent. It
estimated, however, to rise at its highest part, which is
posite Madras, to the height of 3000 feet; and Banga-
re, which is within the chain, was found by barometri-
l observation to be 2900 feet above the level of the sea.
r Buchanan, who had an excellent opportunity of ob-
rving the strata of these mountains, where the rock was
t away to form the road, describes their component
rts to be granite, consisting of white felspar and quartz,
th dark green mica, in a small proportion to the other
o ingredients. The rocks appear to be stratified; but
e strata are broken and confused. In some places they
e almost horizontal, and in others vertical, with all in-
rmediate degrees of inclination. The country above
e Ghauts, about Naiekan Eray, rises into swells like the
nd in many parts of England, and is overlooked by high
rren peaks, which close the view to the eastward. The
untry is but poorly cultivated, and is far from populous.
r Buchanan judged that not above one half of the coun-
y had been ploughed; and about a tenth part of the
hole rises into hills too steep for the plough. The soil
the gently swelling ground is very poor, and covered
ith coppice, having a few large trees intermixed. The
ppice land serves for pasture; and the bushes supply the
tives with fuel. Reservoirs are constructed like those
low the Ghauts; and the watered fields are productive
rice. The want of water, however, is the great draw-
ck on agriculture throughout all the eastern parts of the
pper Carnatic. The mountains produce iron ore, which
washed down by the torrents, and, being found in the form of black sand, is smelted by the natives. Each forge pays a certain tribute in iron, for permission to carry on the work. These mountains abound in rude and magnificent scenery, and there is a number of passes through them, the principal of which are those leading to Seringapatam and Poonah. Many of these roads have been formed with great labour across the mountains; but they are soon ploughed into inequalities by the mountain torrents, and are thus as rough as before. Among the lofty peaks of these mountains large tracts of barren land are to be found; the country is naked, and is not even clothed with forests. The hills next the Vellore road by Sautghur are covered with large stones, among which grow many small trees and shrubs, with occasionally a tamarind tree of great age and size. The pass here has been greatly improved, being widened and levelled since the conquest by the British; and is now practicable for artillery.

Ghauts, *Western*. This great chain of mountains runs along the peninsula of Hindustan, from Cape Comorin to the Tuptee or Surat river, at the distance of not more than sixty or seventy, and in some places not above forty miles from the western shore of the Indian peninsula, namely, the coasts of Malabar, Canara, &c.; and they are frequently visible from the sea, to which at one point they approach within six miles. By this peculiar configuration of the country all the great rivers of the peninsula of India run down the eastern slope of these mountains into the Bay of Bengal, there not being sufficient space for the collection of any great body of water on the western declivity, which is of greater elevation, and more abrupt in its ascent. The range is generally computed to rise to between 3000 and 4000 feet above the level of the sea. These mountains do not terminate in a point or promontory, but bend eastward in a wavy line parallel to the river, and are afterwards lost among the hills in the neighbourhood of Boorhanpoor. These hills extend about 800 miles in length, with the exception of a break in the ridge about sixteen miles wide, where the river Paniany takes its course from the Coimbetore country to the sea; and here it is well known that ships which navigate the Malabar coast during the north-east monsoons commonly experience a stronger gale in the neighbourhood of Paniany than elsewhere; a circumstance which Major Rennell ascribes to this opening in the Ghaut Mountains.[1] The altitude of this mountain chain is sufficient to intercept the great body of the clouds which are alternately impelled across the continent of India by the south-west and north-east monsoons; and accordingly these winds occasion a rainy season on one side of the mountains only, so that while the periodical rains are deluging the country on one side, the weather is serene and dry on the other. But it is only a particular tract of country that is sheltered from rain by the ridge of the Ghauts; for the clouds do pass over, but at too great a height and too much attenuated to be condensed into rain. At a greater distance, however, they collect into masses, and occasion a rainy season in the countries farther to leeward. Thus, at Nagpoor, in the very centre of India, the seasons differ but little from their usual course in Bengal and on the western side of India. They have a rainy season occasioned by the south-west monsoon, though it is not so violent as in Bengal. At the mouth of the Godavery, and in the neighbourhood, the south-west monsoon occasions a rainy season, when the Godavery is swollen and overflows; and this country is about the same distance to leeward of the Ghauts as Nagpoor. Major Rennell suggests that the clouds which occasion the rainy season at the mouth of the Godavery may come from Cape Comorin, though from the prevalence of westerly winds this appears doubtful. But it is certain that the clouds which bring rain at Nagpoor must pass over the Ghauts. Madras lies in the sheltered tract, though at least 300 miles to leeward of the Ghauts. The country near the mouth of the Godavery is about 200 miles more. It would be curious, if we had facts for such a speculation, to trace the limits between wet and dry, and thus to ascertain the influence which this elevated and extensive mountain chain exercises on the climate of the Indian peninsula; but without fuller and more minute information we can scarcely enter into such an inquiry.

---

[1] Rennell, *Memoir of a Map of Hindustan*, p. 196.

The Western Ghauts, about the fifteenth degree of north latitude, although they are steep and stony, are by no means rugged or broken with rocks. On the contrary, in the country near Cutaki the stones are buried in a rich mould, and in many places are not visible until they are dug up. Thus, instead of the naked, sun-burnt, rocky peaks, so common in the eastern chain, these mountains are clothed with stately forests. Dr Buchanan mentions that he had nowhere seen finer trees, nor any bamboos that could be compared to those he saw there. These bamboos compose a large part of the forest; they grow in detached clumps, with open spaces between, and equal in height to the most stately palms, which are also found in great abundance. There is no underwood nor creepers to interrupt the traveller who may choose to wander in any direction through these woods. But there are numerous tigers, which, joined to the unhealthiness of the climate, renders any long stay there uncomfortable. About midway up the mountain the teak becomes common; but it is very inferior in size to other trees. Roads have been formed through these mountains with great labour, out of a bed of loose rock. These roads are ploughed up by torrents during the rainy season, which wash away their softer parts, and leave single rocks of four or five feet diameter standing in the centre. The difficulty formerly experienced in penetrating these mountain passes was very great. In 1791, when the Bombay army was advancing to the Mysore through the Poodicherrim pass, it required two days to draw up twenty light field-pieces two miles, and three weeks to bring up the other artillery to the top of the Ghauts.

GHENT, a city, the capital of the province of East Flanders. It stands on the river Scheldt, where it receives the waters of the Lys, the Lieve, and the More, and is connected with several navigable canals, which form twenty-six islands, over which there are many bridges. It contains about 10,000 houses, and 30,000 inhabitants. It is a sumptuously built ancient city, with many public buildings, some venerable for their antiquity, and others for their architecture. It was before 1830 a place of most extensive manufactures, which had grown up in the preceding fifteen years with a degree of rapidity which has no parallel on the Continent. The commerce and the benevolent institutions were, up to the same period, in a most meritorious state, and yet improving. It is to be hoped that peace may restore the city to its former state of prosperity. Long. 3. 38. 30. E. Lat. 51. 3. 21. N.

GHEP, or Gheep, a district of Hindustan, in the province of Lahore, situated principally between the thirty-second and thirty-third degrees of north latitude. It is bounded on the north-west by Sohaan, and on the south-east by Jhylum rivers. It produces a considerable quantity of fossil salt, great part of which is exported to the more eastern and southern provinces of Hindustan. Part of it belongs to the Sikks, and the remainder to the Afghans. The principal towns are Pirhala, Muckealah, and Varsha.

GHERIAH, a fortress of Hindustan, in the south of India, situated on a rocky promontory in the province of Concan, about one mile long, and a quarter of a mile broad. It is joined to the main land by a narrow neck of land; and lies about a mile from the entrance of a capacious harbour, formed by the mouth of a river which descends from the Western Ghauts. It was taken possession of by the Mahrattas in the seventeenth century; and in 1707, Conajee Angria had established an independent sovereignty here, and possessed a numerous piratical fleet. The depredations of these pirates drew on them the vengeance of the British; and in 1756 Angria's fleet was destroyed by Admiral Watson and Colonel Clive. The first which was taken was found to contain 206 pieces of ordnance, and an immense quantity of ammunition and naval stores, besides L.120,000 in specie or valuables.

GHEROUD, a town of Hindustan, in the province of Khandesh, belonging to the Mahrattas. Long. 79. 49. E. Lat. 21. 58. N.

GHIDDILOW, a town of Bengal, in the district of Conch Beyhar, situated on the northern bank of the Durlah river, which divides that district from Rungpore. Long. 89. 38. E. Lat. 26. N.

GHIDDORE, a town of Bengal, district of Monghir, situated on the road leading from Calcutta to Patna, through Birbhoom. The fort which it formerly possessed is now in a state of ruin. Long. 86. 18. E. Lat. 24. 50. N.

GHILAN, or Gheelan, a province of Persia, which runs along the south-western shore of the Caspian Sea. It is bounded on the south and south-east by Irak and Mazunderan, on the north by Shirvan, and on the west by Azerbijan. It is hemmed in on the south and west by the Elburz range of mountains, which, at the distance of about fifty miles, runs along the shore of the Caspian Sea, and rises to a great height, like a steep wall. The breadth of the low country, from the sea to the foot of the hills, varies exceedingly; the mountains advancing sometimes to the water's edge, and in other places retiring to a distance of thirty or forty miles. The boundary of the province, along with that of the contiguous province of Azerbijan, runs along the elevated crests of the mountains in a very irregular and indefinite line; in some places contracting its whole breadth to thirty, in others enlarging it to seventy miles. The whole coast of Ghilan is lined with a belt of impenetrable forest; and behind this barrier are deep back-waters and extensive morasses. On the south, the passes through the mountains are of extreme steepness, difficulty, and length; so that the province is strongly defended by nature against an invading enemy. The plains extending from the Caspian Sea to the mountains are well watered, verdant, and beautiful; the soil is fertile, and yields abundantly rice, wheat, hemp, hops, and many kinds of fruit, such as lemons, oranges, peaches, and pomegranates. Grapes are in the greatest plenty; and the vines which grow wild in the mountains, support themselves, as in Georgia, on the trunks and branches of trees. From want of attention to their culture, they are not however of the best quality, and, like other fruits in Ghilan, are esteemed unwholesome. But of all the productions in this province, that of silk is the most celebrated. The cultivation of this commodity, which employs the industry of the country, and enriches the natives, constitutes the principal trade of Ghilan, and is annually exported in great quantities from Resht and Lankeroon to Astrakhan. The only river of any consequence is the Kizilozien, which descends from the Elburz Mountains with the rapidity of a torrent, and flows with a meandering course through Ghilan to the Caspian Sea. There are few places in Ghilan deserving the appellation of towns. Resht, containing about 80,000 inhabitants, and Lahajan, stand almost alone. Enzellee is but a poor shipping village, dependent on Resht; and Lankeroon, an open roadstead at the mouth of a river, is upon Lahajan. Fornen, Massouleh, Kiskar, and Teregoraum, are large villages, in which there are tolerable bazars;

Ghoraghaut.

d there may be many other villages as populous, though
t so well established marts for trade. On the other hand,
rkets are periodically held at places which, except at
ese particular times, are almost destitute of inhabitants.
roughout the whole of Ghilan, and the neighbouring
ovinces of Astrabad and Mazunderan, the population
y be divided into two classes; the first inhabiting the
ins, and living stationary in towns or villages, where
ey cultivate rice, wheat, cotton, sugar, silk, and are of
aceable and industrious habits; the second class, in-
iting the skirts of the hills, and the valleys amongst
m, as well as the villages nearest their base, but who
ire during the heat of summer to elevated regions, thus
grating with their flocks in quest of pasture, according
the change of seasons. In the northern parts of Ghilan
the Talish, a fierce tribe of mountaineers, who unite
ny of the better qualities of highlanders with the bar-
rity of savages. They are continually marauding among
emselves, and plundering their immediate neighbours;
d neither property nor life are safe in their hands. They
brave, and devoted to their chiefs; and they are also
tive, and patient of fatigue; but they are treacherous,
rciless, and rapacious towards all the world besides.
ey are for the most part spare, raw-boned men, of ro-
st though not tall frames. Their dress consists of a
se pair of trousers; the only vest they wear is fitted
ht to the body; and the head is covered by a sheep-
n cap of red or black wool. About the waist they wear
leathern girdle, from which depends the formidable
ilanee knife, broad and two-edged, its blade varying
m one to two feet in length, and from two to three
hes in breadth, exceedingly sharp, and ending in a point,
l very deadly in brawls and private quarrels. Over
ir shoulder they carry their toffing or matchlock, in the
of which they are exceedingly expert. The revenue
lded by this province amounts to about 210,000 to-
uns, or L.115,000 sterling, a year. This revenue arises
m a tax on the export of silk goods and silk, a tax on
ports, and a land-tax. We have no accurate account
he population. The cattle are not of a very large size.
e cows resemble the lesser breeds of that animal in In-
; the sheep are also small; and no large horses are
d in these provinces; but there are excellent ponies,
ich answer all purposes much better, as they are strong
l stout, and carry enormous loads through the worst
ds in winter, although after long showers they sink to
girths at every step. Ghilan was ceded by the king
ersia to Russia in 1724; it was taken possession of by
herine II. in 1780, and restored to Aga Mahommed
an in 1797. The southern parts are subject to Persia;
towards the north, the extensive district of Talish is
d by Mustapha Khan, a rebellious and independent
ef, who, finding the power of Persia too great for him,
ted the Russians to his assistance, promising at the
e time to yield them obedience as sovereigns. In the
r 1812, he, along with a Russian garrison consisting of
men, were driven by the Persians out of Lankeroon,
ch was garrisoned by 1500 irregular Ghilanee troops,
ides two battalions of Persian infantry, and a company
rtillery. It was attacked on 13th June with 2000 in-
ry, 1000 Cossacks, and three vessels of war, and was
ied by assault, with a loss of 1200 men. Mustapha
n continued till his death in possession of Russian Ta-
, acknowledging a nominal obedience to the authorities
hat empire, who never demanded more; and he has
n succeeded by seven sons, who have shared between
m the whole country. (Kinneir's *Geographical Me-*
r of the Persian Empire; Fraser's *Travels and Adven-*
s in the Persian Provinces, &c.)

HIZNI, a district of Afghanistan, situated between
thirty-third and thirty-fourth degrees of north latitude, and between the sixty-eighth and sixty-ninth of east longitude. It is a table land, interspersed with a few hills, and possesses a very cold climate. The inhabitants, who are of the Ghiljie tribe, are all shepherds, who raise a number of sheep and lambs. The district is but thinly peopled. The principal towns are Ghizni, Kurrabaugh, and Gurdaiz.

GHIZNI, a celebrated city of Afghanistan, the chief town of the above district, and forming the capital of a powerful empire, reaching from the Tigris to the Ganges, and from the Jaxartes to the Persian Gulf. It is now reduced to about 1500 houses, besides suburbs without the walls. Its situation is on a height, at the foot of which flows a pretty large stream. It is surrounded by stone walls, and contains three bazars of no great breadth, with high houses on each side, and a covered chaursoo or exchange, besides several dark and narrow streets. Ghizni was splendidly adorned by the Ghiznavi princes, especially by Sultan Mahmoud. But most of these splendid buildings have been long levelled with the dust; and only some few remains of the ancient grandeur of the city are to be seen in the neighbourhood, particularly two lofty minarets, which stand at some distance from each other, and are of different heights, the least upwards of a hundred feet high. The tomb of Sultan Mahmoud is also standing, about three miles from the city. It is covered with a cupola, and is a spacious rather than a magnificent building. The doors, which are large, are of sandal wood, and said to have been brought by the sultan, as a trophy, from the famous temple of Somnaut in Guzerat, which he sacked in his last expedition to India. The tombstone is of white marble, on which are sculptured Arabic verses from the Koran; and at its head lies the plain but mighty wooden mace, with a head of metal so heavy that few men can now use it. There are likewise some thrones or chairs, inlaid with mother of pearl, in the tomb, which are said to have belonged to Mahmoud. There are other ruins of less note, among which may be mentioned the tombs of Behtole the wise, and that of Hakeem Sunanee, a poet. But there are no remains of the magnificent palaces of the Gaznavide kings, or of the mosques, baths, and caravanserais which once adorned the capital of the East. Of all the antiquities of Ghizni, the most useful is an embankment across a stream, which was built by Mahmoud, and which still supplies water to the fields and gardens round the town. This city was in the year 960 taken possession of by Abistagy, a rebel governor of Khorassan, who threw off his allegiance to the Samonavian dynasty of Persia, and founded a new kingdom. He was succeeded by his son-in-law Subactageen, who ascended the throne in 975, and extended his dominions to the banks of the Indus. Mahmoud, who succeeded, invaded India several times, and raised the glory of the Ghiznean empire to its highest pitch; and he first obtained from the khalif the title of Sultan. He died in the year 1030, and was buried in a magnificent tomb. The kingdom continued to flourish till the year 1116, when a Persian army invaded the country, and took the capital. It was again taken about the year 1150, by Alaaddeen, the prince of Ghore. Irritated by an insult offered to his family by the inhabitants of Ghizni, he gave up the town to be pillaged by his soldiers, who for seven days massacred the inhabitants, and destroyed all the public buildings, sparing only the tombs. From this period may be dated the decline of the city. The royal family fled to Lahore, where, languishing through two weak reigns, the dynasty terminated in the person of Khosroo II. and in the year 1189. The travelling distance from Delhi by Cabul is 917 miles; from Cabul eighty-two miles. Long. 68. 22. E. Lat. 33. 36. N. (Elphinstone's *Account of Cabul*; Rennell's *Memoir of a Map of Hindustan*; Foster, &c.

GHORAGHAUT, a district of Bengal, containing about a hundred and fifty square miles, but formerly much more extensive, as it not only embraced great part of the district of Dinagepore, but also extended across the Brahmaputra river, and included the small district of Carrybary; it is pleasantly situated on the western bank of the Currutya river, and formerly carried on a considerable trade with Bootan for Tangan horses, musk, &c. Long. 89. 25. E. Lat. 25. 13. N.

Ghoraghaut, a fortress of Hindustan, in the province of Gurjerat. It is the capital of the above district, situated on the borders of the extensive salt morass of the Run, which affords good pasturage for horses, and divides Gurjerat from Cutch. It serves as a barrier fortress to the Run; a strong garrison being always kept in it by the Jam of Noanagur.

GHORE, or Ghour, a considerable district of Afghanistan, situated between the thirty-fifth and thirty-seventh degrees of north latitude, and the sixty-seventh and sixty-ninth degrees of east longitude. This was formerly one of the Persian governments; but in the twelfth century its chiefs became independent, overturned the Ghiznian empire, and carried their arms as far as Benares. One of their slaves named Cuttub founded, about the year 1206, the Mahommedan kingdom of Delhi. This country was overrun in the thirteenth and fourteenth centuries by the armies of Genghis Khan and Tamerlane, and it is now in possession of the Usbec Tartars. The Ghory tribe, being of pastoral habits, have emigrated to the vicinity of Peshawer, and are now subdivided into three tribes. Its chief towns are Ghore and Firoy Koh. Ghore is the name of the capital, and was once the residence of a long line of sovereigns. It was taken by the king of Kharezm, and was subsequently sacked by the armies of Genghis and Tamerlane, from which it has never recovered, and is now scarcely known. Long. 67. 48. E. Lat. 35. 45. N.

GHOSEGONG, a small town in the Garrow country, on the western frontier of Bengal, and situated on the west side of the Natee river. It consists of a considerable number of thatched houses belonging to the Garrow tribe, some of them a hundred and fifty feet long and thirty wide. The soil in the vicinity is good, and produces rice, mustard seed, and hemp. The pasture is also good, and the ghee produce is of an excellent quality,

GHOORBUND, a district of Afghanistan, situated to the south of the Hindu Coosh range of mountains, about fifty-six miles to the north-north-west of Cabul. It is a fertile valley, which yields abundance of wheat; but the favourite food of the natives is dried mulberries. It produces also lapis lazuli. The inhabitants are of Persian descent, being of the Sheea sect, while all the other Afghans are Soonees.

GONFODE, or Ghunfude, a sea-port of Arabia, in the province of Hedsjaz, in Arabia. All vessels carrying coffee to Jidda are compelled to anchor here, and to pay a duty. It is 145 miles south of Mecca.

GHURKA. See Aurungabad.

GHYSEABAD, a town of Hindustan, in the Mahratta territories, in the province of Malwah, 50 miles south from Chatterpoor. Long. 79. 56. E. Lat. 24. 8. N.

GHOST, an apparition, or spirit of a person deceased, rendered visible to the eye of sense. See Apparitions.

GIAGH, in *Chronology*, a cycle of twelve years, in use amongst the Turks and Cathayans or Chinese. Each year of a giagh bears the name of some animal; the first that of a mouse, the second that of a bullock, the third that of a lynx or leopard, the fourth that of a hare, the fifth that of a crocodile, the sixth that of a serpent, the seventh that of a horse, the eighth that of a sheep, the ninth that of a monkey, the tenth that of a hen, the eleventh that of a dog, and the twelfth that of a hog. The day is also divided into twelve parts, called *giaghs*, and distinguished by the name of some animals. Each giagh contains two of our hours, and is divided into eight kehs, each equal to a quarter of an hour with us.

GIANNONE, in Latin Jannonius, Peter, a celebrated Neapolitan writer and historian, was born at Ischitella, a small town in the province of Capitanata. Having acquired the elements of a liberal education under the paternal roof, he was sent by his father, at the age of eighteen, to Naples, there to complete his studies, and particularly to study jurisprudence. Being placed under the immediate tuition of Dominico Aulisio, who not only excelled in the qualifications necessary for training young men to the bar, but was also profoundly conversant with Greek and Roman literature, history, philosophy, and indeed all the learning of his time, Giannone made so rapid progress in his studies, both in philosophy and jurisprudence, and evinced so great penetration of mind, that he was admitted into the society or club which met at the house of Gaetano Argento, one of the most distinguished advocates of Naples, who combined the cultivation of letters with the practice of his profession. This circumstance appears to have materially influenced, if not in fact determined, the character of his subsequent pursuits. He applied himself with great ardour to the study of jurisprudence on philosophical principles, and soon gave proofs of his capacity for investigating and illustrating the sources of that science by several learned dissertations *De Originibus Juris.* His inquiries, however, having disclosed to him much respecting the origin and mutations of laws, and the vicissitudes of nations, which had escaped the penetration of ordinary jurisconsults, he conceived the design, with the approbation of Argento, of writing a civil history of the kingdom of Naples, comprehending an account of the origin and progress of its laws and government, and an exposition of the causes which led to the gradual abolition of ancient customs and institutions. But this work, interrupted from time to time by the affairs of the bar, was not completed until after the lapse of twenty years, and only appeared in 1723, under the title of *Istoria Civile del Regno di Napoli,* in four volumes 4to. Giannone took as his guide Angelo de Costanzo, whose history of Naples, which was then accounted the best, he almost entirely transfused into his work; but his distinguishing merit consists in the valuable expositions he has given relative to the ecclesiastical and civil constitution, and to the laws and customs of the kingdom. Although the style is neither correct nor elegant, the philosophical spirit, the erudition, and the profound research, which this history exhibits, secured it a high reputation. But the author perhaps affects too much passion against the court of Rome, the proceedings of which, however censurable in themselves, should have been treated by a writer like Giannone, not with the impassioned bitterness of a controversialist, but with the dignified and judicial calmness of a philosophical historian. The consequences of this asperity were such as might have been expected. The freedom with which he treated ecclesiastics generally, and the boldness with which he discussed several topics relating to the origin of the papal power, raised a storm against him, which neither the authority of the viceroy, Cardinal Althann, nor the credit of the municipality of Naples, of which he had been elected advocate, could allay, or even mitigate. "I know not, indeed," said Argento, when speaking to him on this subject, "whether I should congratulate you or condole with you; for I very much fear lest the crown of laurel which now encircles your brows should become a crown of thorns." Having been several times insulted by the populace, and at length excommunicated by the archiepiscopal court, Giannone, seeing his work placed in the *index expurgatorius*, left Naples on the 29th of April 1723, and went to seek an asylum at Vienna. The Emperor Charles VI. regarded him at first with an unfavourable eye; but the protection of such men as Prince Eugene, the Chancellor Zinzendorf, the celebrated Count de Bonneval, and the Chevalier Garelli, first physician to the emperor, procured him a pension of a hundred florins on the ecretaryship of Sicily. Although relieved from his exommunication by Cardinal Pignatelli, archbishop of Nales, he did not restrain himself from composing several ttle satires against his sentence, and particularly against e prohibition of his book; but by the advice of his friends e only circulated these in manuscript. It is in his smaller orks that his resentment against the court of Rome knew o bounds. During his stay at Vienna, where he enjoyed e favour of the great and of men of letters, he laboured a work entitled *Il Triregno, ossia del regno del Cielo, ella Terra, e del Papa,* which occupied him nearly twelve ears, and to which he only put the last touches at Genea. This work, in which man is successively represented the state of nature, under the law of grace, and under e temporal dominion of the popes, comprehends ten pochs, the first three of which extend to the ninth cenury; but the remainder has not been completed. Don arlos having ascended the throne of Naples and of Sicily 1734, Giannone lost his pension and all his hopes. Beg constrained to quit Vienna, he retired to Venice, here he was received with every mark of distinction, by ersons of quality and men of letters, particularly by the enator Angiolo Pisani, who gave him a lodging in one of is houses. He refused the appointment of counsellor of he republic, and the chair of Roman law in the univerity of Padua, ingenuously confessing that he was not in a ondition to explain the laws in the Latin language, acording to the usage of the schools. But the repose which e hoped to enjoy at Venice was not of long duration. enounced as unfavourable to the pretensions of the reublic over the Adriatic, he endeavoured to avert the storm y publishing a *Lettera intorno al dominio del mare Adritico ed ai trattati seguiti in Venezia tra Papa Alessandro II. e l'Imperador Federigo Barbarossa;* but as the state nquisitors had taken umbrage at the prolonged visits paid y him to the ambassadors of France and Spain, his remoal was decided on, and, in the night of the 23d September 735, sbirri seized and conducted him in a small boat or arque to the frontiers of the territory of Ferrara. The aprehension of still greater misfortunes now induced him to hange his name to that of Antonio Rinaldo, under which e sojourned at Modena, Milan, and Turin, and arrived ith his son at Geneva, on the 5th of December. His reutation, which had preceded him in different cities, proured him in the last-mentioned place the most satisfactory eception on the part of Dr Turretin, the minister Vernet, and the bookseller Bousquet, who furnished him with the neans of living at his ease. In 1736 he was preparing to rint a volume of supplement to his history, when, having een conducted by a perfidious friend to pass Easter in a catholic village belonging to the king of Sardinia, he was arrested by order of that sovereign, and his manuscripts seized and conveyed to Rome. He was himself conducted to the castle of Miolan, and thence to the fort of Ceva, where, in his calmer moments, he employed himself in translating various works into Italian, in writing on politics, and in preparing memoirs of his life. The discussion which arose between the courts of Rome and Turin on the nomination to consistorial benefices in the states of the king of Sardinia, and which was terminated by the concordat of 1738, furnished Giannone with an occasion of writing, in favour of the rights of the sovereign, a memoir, which he sent to the king. His Sardinian majesty appeared to receive it with pleasure; but, strange to add, he caused the author to be more closely confined than before, and ordered him to be transferred to the citadel of Turin, where he passed twelve consecutive years in trouble and agitation. It was in this fortress that, giving ear to the persuasions of Father Prever of the Oratory, Giannone retracted, on the 4th April 1738, the maxims which had been condemned in his history. But this submission did not procure him his liberty; for he died in prison on the 7th of March 1758, aged seventy-two years. In 1760 his posthumous works were published at Lausanne, in one volume 4to, under the title of *Opere Postume in difesa della sua Storia civile del regno di Napoli, con la di lui professione di fede.* The history of Giannone was translated into French by Louis Bochat of Lausanne; and among the re-impressions of the work may be distinguished that which appeared with illustrations by the Abbé Cestari. It has been highly commended by Gibbon in his *Extraits de mon Journal* (Miscellaneous Works, vol. v. p. 413, 8vo ed.) "The candour, penetration, and freedom of this excellent lawyer," says he, "will ever ensure to this work the esteem of all wise men. But," he adds, "churchmen are not always of the number." In the number of the refutations which have appeared, it is only necessary to mention the *Riflessioni morali e teologiche sopra l'Istoria civile del regno di Napoli*, by Eusebio Filopatro (Father San-Felice, a jesuit), in two volumes 4to, an extract of which may be seen in the *Mémoires de Trevoux* for January 1730. (Fabroni, *Vitæ Italorum*, vol. xiii. v. *Petrus Jannonius.*) (A.)

GIANT, a person of extraordinary bulk and stature. The romances of all ages have furnished us with so many extravagant accounts of giants of incredible bulk and strength, that the existence of such people is now generally disbelieved. It is commonly thought that the stature of man has been the same in all ages; and some have even pretended to demonstrate mathematically the impossibility of the existence of giants. Of these our countryman Maclaurin has been the most explicit. "In general," says he, "it will easily appear, that the efforts tending to destroy the cohesion of beams arising from their own gravity only, increase in the quadruplicate ratio of their lengths; but that the opposite efforts, tending to preserve their cohesion, increase only in the triplicate proportion of the same lengths. From this it follows, that the greater beams must be in greater danger of breaking than the lesser similar ones; and that though a lesser beam may be firm and secure, yet a greater similar one may be made so long, that it will necessarily break by its own weight. Hence Galileo justly concludes, that what appears very firm and succeeds very well in models, may be very weak and infirm, or even fall to pieces by its own weight, when it comes to be executed in large dimensions according to the model. From the same principle he argues, that there are necessary limits in the operations of nature and art, which they cannot surpass in magnitude. Were trees of a very enormous size, their branches would fall by their own weight. Large animals have not strength in proportion to their size; and if there were any land animals much larger than those we know, they could hardly move, and would be perpetually subject to the most dangerous accidents. As to the animals of the sea, indeed, the case is different; for the gravity of the water in a great measure sustains those animals, and in fact these are known sometimes to be vastly larger than the greatest land animals. Nor does it avail against this doctrine to tell us, that bones have sometimes been found which were supposed to have belonged to giants of immense size, such as the skeletons mentioned by Strabo and Pliny, the former of which was sixty cubits high, and the latter forty-six; for naturalists have concluded on just grounds, that in some cases these bones had belonged to elephants; and that the larger ones were bones of whales, which had been brought to the places where they were found by the revolutions of nature that have happened in past times; though it must be owned that there appears no reason why there may not have been men who have exceeded by some feet in height the tallest we have seen."

It will be easily seen, that arguments of this kind can never be held as conclusive, because, along with an increase of stature in any animal, we must always suppose a proportional increase in the cohesion of the parts of its body. Large works sometimes fail when constructed on the plan of models, because the cohesion of the materials of which the model is made, and of the large work, are the same; but a difference in this respect will produce a very remarkable difference in the result. Thus, suppose a model is made of fir-wood, the model may be strong and firm enough; but a large work made also of fir, when executed according to the plan of the model, may be so weak that it will fall to pieces by its own weight. If, however, we make use of iron for the large work instead of fir, the whole will be sufficiently strong, even though made exactly according to the plan of the model. The same thing may be said regarding large and small animals. If we could find an animal whose bones exceeded in hardness and strength the bones of other animals as much as iron exceeds fir, such an animal might be of a monstrous size, and yet be exceedingly strong. In like manner, if we suppose the flesh and bones of a giant to be greatly superior in strength and hardness to the flesh and bones of other men, the great size of his body will be no objection at all to his strength. The whole of the matter therefore concerning the existence of giants must rest upon the credibility of the accounts we have received from those who pretend to have seen them, and not on any arguments drawn *a priori*. In a memoir read before the Academy of Sciences at Rouen, M. Lecat gives the following account of giants who are said to have existed in different ages.

"Profane historians have given seven feet of height to Hercules, their first hero; and in our days we have seen men eight feet high. The giant who was shown in Rouen in 1735 measured eight feet some inches. The Emperor Maximin was of that size; Shenkins and Platerus, physicians of the last century, saw several persons of that stature; and Goropius saw a girl who was ten feet high. The body of Orestes, according to the Greeks, was eleven feet and a half; the giant Galbara, brought from Arabia to Rome under Claudius Cæsar, was near ten feet; and the bones of Secondilla and Pusio, keepers of the gardens of Sallust, were but six inches shorter. Funnam, a Scotsman, who lived in the time of Eugene II. king of Scotland, measured eleven feet and a half; and Jacob Lemaire, in his voyage to the Straits of Magellan, reports, that on the 17th of December 1615, they found at Port Desiré several graves covered with stones; and having the curiosity to remove the stones, they discovered human skeletons of ten and eleven feet in length. The Chevalier Scory, in his voyage to the Peak of Teneriffe, says, that they found in one of the sepulchral caverns of that mountain the head of a Gaucho which had eighty teeth, and that the body was not less than fifteen feet in length. The giant Ferragus, slain by Orlando, nephew of Charlemagne, was eighteen feet in height. Rioland, a celebrated anatomist, who wrote in 1614, says, that, some years before, there was to be seen in the suburbs of St Germain the tomb of the giant Isoret, who was twenty feet in height. In Rouen, in 1509, whilst digging in the ditches near the Dominicans, they found a stone tomb containing a skeleton whose skull held a bushel of corn, and whose shin-bone reached up to the girdle of the tallest man there, being about four feet in length, and consequently the body must have been seventeen or eighteen feet in height. Upon the tomb was a plate of copper, on which was engraved, 'In this tomb lies the noble and puissant lord the Chevalier Ricon de Vallemont, and his bones.' Platerus, a famous physician, declares that he saw at Lucerne the true human bones of a subject which must have been at least nineteen feet high. Valence in Dauphiné boasts of possessing the bones of the giant Bucart, tyrant of the Vivarais, who was slain with an arrow by the Count de Cabillon, his vassal. The Dominicans had a part of the shin-bone, with the articulation of the knee, and his figure painted in fresco, with an inscription, showing that this giant was twenty-two feet and a half in height, and that his bones were found in 1705, near the banks of the Morderi, a little river at the foot of the mountain of Crussol, upon which, according to tradition, the giant had his residence.

"On the 11th January 1613, some masons digging near the ruins of a castle in Dauphiné, in a field which, by tradition, had long been called the *giant's field*, at the depth of eighteen feet discovered a brick tomb thirty feet long, twelve feet wide, and eight feet high; on which was a gray stone, with the words *Theutobochus Rex* cut thereon. When the tomb was opened, they found a human skeleton entire, twenty-five and a half feet long, ten feet wide across the shoulders, and five feet deep from the breast-bone to the back. The teeth were each about the size of an ox's foot, and the shin-bone measured four feet. Near Mazarino, in Sicily, in 1516, was found the skeleton of a giant thirty feet high; his head was the size of a hogshead, and each of his teeth weighed five ounces. Near Palermo, in the valley of Mazara, in Sicily, a skeleton of a giant thirty feet long was found, in the year 1548; and another of thirty-three feet high, in 1550. Many curious persons have preserved several of these gigantic bones.

"The Athenians found near their city two famous skeletons, one of thirty-four and the other of thirty-six feet in height. At Totu, in Bohemia, there was found in 758 a skeleton, the head of which could scarcely be encompassed by the arms of two men together; whilst the legs, which they still keep in the castle of that city, were twenty-six feet long. The skull of the giant found in Macedonia in September 1691 contained two hundred and ten pounds of corn. The celebrated Sir Hans Sloane, who treated this matter very learnedly, does not doubt these facts, but thinks the bones were those of elephants, whales, or other enormous animals. Elephants' bones may be shown as those of giants; but they can never impose upon anatomists. Whales, which, by their immense bulk, are more proper to be substituted for the largest giants, have neither arms nor legs; and the head of that animal has not the least resemblance to that of a man. If it be true, therefore, that a great number of the gigantic bones which we have mentioned have been seen by anatomists, and by them have been reputed real human bones, the existence of giants is proved."

With regard to the credibility of all or any of these accounts, it is difficult to determine any thing. If, in any castle of Bohemia, the bones of a man's leg twenty-six feet in length are preserved, we should have indeed a decisive proof of the existence of a giant, in comparison of whom most others would be but pigmies. Nor could these bones be supposed to belong to an elephant; for an elephant itself would be but a dwarf in comparison of such an enormous monster.

GIANT'S *Causeway*, a vast collection of basaltic pillars in the county of Antrim, on the northern coast of Ireland. The principal or grand causeway consists of a most regular arrangement of many hundred thousand columns of a black kind of rock, very hard, almost all of them of a pentagonal figure, but so closely and compactly situated on their sides, though perfectly distinct from top to bottom, that scarcely any thing can be introduced between them. The columns are of an unequal height and breadth; some of the highest, visible above the surface of the strand, and at the foot of the impending angular precipice, may be about twenty feet; and they do not exceed this height, at least none of the principal arrangement. How deep they are fixed in the strand was never yet discovered. This grand arrangement extends nearly two hundred yards, visible at low water, but how far beyond is uncertain; from s declining appearance, however, at low water, it is probable it does not extend under water to a distance any thing equal to what is seen above. The breadth of the principal causeway, which runs out in one continued range of columns, is in general from twenty to thirty feet; at one lace or two it may for a few yards be nearly forty. In his account are not included the broken and scattered ieces of the same kind of construction which are detached from the sides of the grand causeway, as they do not ppear to have ever been contiguous to the principal arrangement, though they have frequently been taken into he width; and this has been the cause of the wild and issimilar representations of this causeway, which different accounts have exhibited. The highest part of the auseway is the narrowest, at the very foot of the impending cliff from which the whole projects, where, for four or ve yards, it is not above ten or fifteen feet wide. The olumns of this narrow part incline from a perpendicular little to the westward, and form a slope on their tops, y the very unequal height of the columns on the two ides, by which an ascent is made at the foot of the cliff, rom the head of one column to the next above, *gradatim*, o the top of the great causeway, which, at the distance of alf a dozen yards from the cliff, obtains a perpendicular osition, and, lowering in its general height, widens to bout twenty or between twenty and thirty feet, and for hundred yards nearly is always above water. The tops f the columns for this length being nearly of an equal eight, they form a grand and singular parade, that may e easily walked on, but rather inclining to the water's edge. From high-water mark, as it is perpetually washed y the beating surges on every return of the tide, the platform lowers considerably, and becomes more and more uneven, so as not to be walked on but with the greatest care. At the distance of about a hundred and fifty yards rom the cliff it turns a little to the eastward for twenty r thirty yards, and then sinks into the sea. The figure f these columns is almost without exception pentagonal, r composed of five sides; there are but very few of any ther figure introduced; some, indeed, there are of three, our, and six sides, but the generality of them are five-sided; and the spectator must look very nicely to find ny of a different construction. Yet, what is very extraordinary, and particularly curious, there are not two columns in ten thousand to be found, which either have heir sides equal among themselves, or whose figures are like. Nor is the composition of these columns or pillars ess deserving the attention of the curious spectator. They are not of one solid stone in an upright position, ut composed of several short lengths, curiously joined, ot with flat surfaces, but articulated into each other like all and socket, or like the joints in the vertebræ of some f the larger kinds of fish, the one end at the joint having cavity, into which the convex end of the opposite is exactly fitted. This is not visible except by disjoining two f the lengths. The depth of the concavity or convexity s generally about three or four inches. And, what is still more remarkable of the joint, the convexity and the corresponding concavity is not conform to the external angular figure of the column, but exactly round, and as large s the size or diameter of the column will admit; and consequently, as the angles of these columns are in general extremely unequal, the circular edges of the joint are seldom coincident with more than two or three sides of the pentagon, and from the edge of the circular part of the oint to the exterior sides and angles they are quite plain. t is still further remarkable, that the articulations or those oints are frequently inverted; in some the concavity is upwards, and in others the reverse. This occasions the variety and mixture of concavities and convexities on the ops of the columns, which is observable throughout the platform of this causeway, yet without any discoverable design or regularity with respect to the number of either. The length also of these particular stones, from joint to joint, is various; in general, they are from eighteen to twenty-four inches in length; and, for the most part, longer towards the bottom of the columns than nearer the top, and the articulation of the joints something deeper. The size or diameter of the columns is likewise as different as their length and figure; but in general they are from fifteen to twenty inches in diameter. There are really no traces of uniformity or design discoverable throughout the whole combination, excepting in the form of the joint, which is invariably by an articulation of the convex into the concave of the piece next above or below it; nor are there any traces of a finishing in any part, either in height, length, or breadth, of this curious causeway. If there is here and there a smooth top to any of the columns above water, there are others just by, of equal height, which are more or less convex or concave, and show them to have been joined to pieces that have been washed, or by other means taken off. And undoubtedly those parts which are always above water have, from time to time, been made as even as might be; whilst the remaining surfaces of the joints must naturally have been worn smoother by the constant friction of weather and walking, than where the sea, at every tide, is beating upon the causeway, and continually removing some of the upper stones, and exposing fresh joints. Further, as these columns preserve their diameters from top to bottom, in all the exterior ones which have two or three sides exposed to view, the same thing may with reason be inferred of the interior columns, whose tops only are visible. Yet, what is equally curious and extraordinary in this phenomenon, it appears that, notwithstanding the universal dissimilitude of the columns, both as to their figure and diameter, and though perfectly distinct from top to bottom, the whole arrangement is so closely combined at all points that hardly a knife can be introduced between them, either on the sides or angles.

The cliffs at a great distance from the causeway, especially in the bay to the eastward, exhibit in many places the same kind of columns, figured and jointed in all respects like those of the grand causeway. Some of them are seen near to the top of the cliff, which in general, in those bays to the east and west of the causeway, is about three hundred feet in height; others again are observed about midway, and at different elevations from the strand. A very considerable exposure of them is seen in the very bottom of the bay to the eastward, about a hundred roods from the causeway, where the earth has evidently fallen away from them upon the strand, and exhibits a most curious arrangement of many of these pentagonal columns in a perpendicular position, supporting in appearance a cliff of different strata of earth, clay, rock, &c. to the height of about a hundred and thirty feet or more above. Some of these columns are between thirty and forty feet high, from the top of the sloping bank below them; and, being longest in the middle of the arrangement, and shortening on either hand, they have obtained the appellation of *organs*, from a rude likeness in this particular to the exterior or frontal tubes of that instrument; and as there are few broken pieces on the strand near it, it is probable that the outside range of columns which now appears is really the original exterior line, to the seaward, of this collection. But how far they extend internally into the bowels of the incumbent cliff is unknown. The very substance, indeed, of that part of the cliff which projects to a point, between the two bays on the east and west of the causeway, seems composed of this kind of materials; for, besides the many pieces which are seen on the sides of the cliff that circulate to the bottom of the bays, particularly the eastern side, there is, at the very point of the cliff, and just above the narrowest and highest part of the causeway, a long collection of them seen, whose heads or tops, just appearing without the sloping bank, plainly show them to be in an oblique position, and about half way between the perpendicular and horizontal lines. The heads of these, likewise, are of mixed surfaces, convex and concave, and the columns evidently appear to have been removed from their original upright to their present inclining or oblique position, by the sinking or falling of the cliff.

GIARITCHAS Isles, a cluster of five small islands, about six miles south-south-west from Makiam. They are of moderate height, and contain many bare rocks intermixed with trees.

GIAVENO, a city of Italy, in the kingdom of Sardinia and province of Susa. It stands on a hill, at whose base the river Sangone flows. It has the remains of an ancient wall, and contains a college. The inhabitants amount to 8300, who are employed in silk manufactures and in tanneries, and make some very good wine.

GIBBET, a machine in manner of a gallows, on which notorious criminals, after execution, are hung in irons or chains, as spectacles *in terrorem*. The word in French, *gibet*, properly denotes what we call gallows; and it is supposed to come originally from the Arabic *gibel*, a mount, or elevation of ground, by reason that gibbets are usually placed on hills or eminences.

GIBBON, Edward, the celebrated author of the Decline and Fall of the Roman Empire, and generally considered as forming, with Hume and Robertson, the triumvirate of great English historians, was descended of an ancient but not very distinguished family of the same name in the county of Kent. His grandfather, a merchant and citizen of London, was, under the Tory administration of the last four years of Queen Anne (1710–1714), appointed one of the commissioners of customs, and sat at the same board with Matthew Prior; but the mercantile man seems to have been better qualified for his station than the poet, at least in the opinion of Lord Bolingbroke, who was heard to declare that he had never conversed with a person who understood more clearly than Mr Gibbon the commerce and finances of England. In the year 1716, he was elected one of the directors of the South Sea Company; and, before his acceptance of this fatal office, he had acquired an independent fortune of sixty thousand pounds. But this fortune was overwhelmed in the shipwreck of the year 1720, when the company failed, and the accumulations of thirty years were swallowed up in a single day. Of the use or abuse of the South Sea scheme this is not the place to say any thing; and the question as to the guilt or innocence of Mr Gibbon may also be passed over without remark or discussion. In the first proceedings against the South Sea directors, however, he was one of the few who were taken into custody; and, in the final sentence, the measure of his fine was determined by the total estimate of his means, which he delivered upon oath to the House of Commons. But a sum of ten thousand pounds was afterwards allowed him for his maintenance; and on this foundation, with the skill and credit of which parliament had not been able to deprive him, he erected the edifice of a new fortune, the greater part of which he prudently secured in the purchase of landed property. He died in his house at Putney, in December 1736, and, by his last will, enriched his two daughters, Catharine and Hester, at the expense of his only son, Edward, the father of the historian, who had married without his consent. This son, who was born in 1707, received the benefit of a liberal education. At Westminster, and afterwards at Emmanuel College, Cambridge, he passed through a regular course of academical discipline. He then proceeded on his travels, but without taking a degree; and, on his return to England, he was chosen member of parliament for the borough of Petersfield in 1734, and again for that of Southampton in 1741. In parliament he joined the party which, after a long and fierce contest, finally succeeded in driving Sir Robert Walpole from power; and his son has not concealed that, in the pursuit of an unpopular minister, he gratified a private revenge against the supposed oppressor of his family in the South Sea persecution. This retaliation, however, was entirely misdirected; for Mr Coxe has clearly proved that, so far from stimulating or exasperating the fury of that time, Walpole endeavoured to stem the torrent of parliamentary vengeance, and to turn the sentiments of the house into the safe channel of moderation.

Edward Gibbon, the future historian of the Roman empire in its decline and fall, was born at Putney, in Surrey, on the 27th April, old style, in the year 1737. His mother, Judith Porten, was the youngest daughter of James Porten, a merchant of London; and he was the eldest of five brothers and a sister, all of whom died in infancy. During his early years his constitution was so feeble, and his life so precarious, that, in the baptism of his brothers, his father successively repeated the Christian name of Edward; and to preserve and rear so frail a being, the most tender assiduity was scarcely sufficient. From this anxious and painful duty his mother's attention was diverted by frequent pregnancy, an exclusive passion for her husband, and the dissipation of the world; but the maternal office was supplied by his maiden aunt, Mrs Catharine Porten, who nursed him with the greatest tenderness, and, during the intervals of convalescence, procured him such instruction as his years and infirm health admitted. After some previous instruction at home, or in a day-school at Putney, he was, at the age of seven, placed under the care of Mr John Kirkby (author of *Automathes*, a philosophical romance), who, for about eighteen months, acted as his domestic tutor. In his ninth year (January 1746), during a lucid interval of comparative health, he was sent to a school at Kingston-upon-Thames, which was then kept by Dr Woodeson and his assistants; but his studies were still frequently interrupted by sickness; and though, by the common methods of discipline, he purchased some knowledge of Latin syntax, he does not speak with much satisfaction of his proficiency, and, after a real or nominal residence of nearly two years, he was finally recalled by his mother's death in 1747. After this event, he spent about two years in the rustic solitude of Buriton, to which his father had retired; and there, principally under the eye of his affectionate aunt, he acquired that invincible love of reading which, he declares, he would not exchange for the treasures of India. In 1749, he was sent to Westminster school, then conducted by Dr John Nicoll, where, within the space of two more years, he reached the third form; but his application was so frequently interrupted by sickness, or rendered useless by debility, that, by medical advice, he was removed to Bath, whence, after an ineffectual trial of the virtues of its mineral waters, he was transported to Winchester, to the house of a physician. From the latter place he returned unimproved in health to Bath, and at length moved with his father to Buriton and Putney, where he so far recovered, that a short and unsuccessful trial was made to renew his attendance at Westminster school. But his infirmities could not be reconciled with the hours and discipline of a public seminary; and as he was not provided with a domestic tutor, who might have watched the favourable moments, and imperceptibly advanced him in learning, he was obliged to be content with such occasional teachers as the different places of his residence could supply.

As he approached his sixteenth year, however, his sufferings entirely ceased. Nature, to use his own words, displayed in his favour her mysterious energies; his constitution became fortified and fixed; and his disorder, instead of gaining strength with his years, and reducing him for fe to the condition of an illiterate cripple, most wonderully vanished. Encouraged by his unexpected recovery, is father placed him at Esher, in Surrey, in the house of ie Reverend Philip Francis, the translator of Horace, who, was expected, would at least inspire him with a taste for ie Latin poets. But this hope was altogether frustrated. Ir Francis preferred the pleasures of London to the inruction of his pupils; and, amidst the perplexity which iis discovery occasioned, young Gibbon was, without furier preparation, hurried by his father to Oxford, where, on ie 3d of April 1752, he was matriculated as a gentleman-ommoner of Magdalen College.

"I arrived at Oxford," says Gibbon, "with a stock of rudition that might have puzzled a doctor, and a degree f ignorance of which a school-boy might have been ashamd." During the preceding three years, although sickness revented him from following a regular course of instrucon, his fondness for books had increased, and he was peritted to indulge without restraint his love of desultory eading. But his indiscriminate appetite subsided by derees into the historical line, and he perused with avidity uch books of history as accident threw in his way, gratiying a curiosity of which he could not trace the source, nd supplying wants of which he felt the craving without eing able to account for his predilections. The assiduous erusal of the Universal History, as the octavo volumes uccessively appeared, and of a treatise by Hearne, the *uctor Historicus*, introduced him to as many of the Greek nd Roman historians as were accessible to an English eader. He also devoured Littlebury's Herodotus, Spelian's Xenophon, Gordon's Tacitus, and "a ragged Proopius" which happened to fall in his way; whilst "many rude lumps" of Speed, Rapin, Mezeray, Davila, Machiael, Fra Paolo, Bower, and others, were swallowed, if not igested by him; and in the descriptions of India and hina, Mexico and Peru, he found an inexhaustible source f gratification. The continuation of Echard's Roman Iistory gave him some insight into the reigns of the sucessors of Constantine; and in Howel's History of the Vorld he found the Byzantine period exhibited on a larer scale. Mahommed and his Saracens soon fixed his ttention; and Simon Ockley, an original in every sense, aving opened his eyes to the true character of both, he was ed from one book to another, until he had ranged round he whole circle of oriental history. The same insatiale ardour urged him to guess at the French of D'Herelot, and to endeavour to construe the barbarous Latin f Pococke's Abulfaragius. The maps of Cellarius and Vells imprinted on his memory the details of ancient georaphy; from Stranchius he imbibed the elements of chroology; the Tables of Helvicus and Anderson, together ith the Annals of Usher and Prideaux, distinguished the onnection of events; the systems of Scaliger and Petaius, of Marsham and Newton, which he could seldom tudy in the originals, formed the subject of frequent meitation; and his sleep was sometimes disturbed by vain ttempts to reconcile the Septuagint with the Hebrew omputation.

In this strange and eccentric course of desultory readig, young Gibbon, whilst ranging at pleasure through uch books as fell in his way, seems to have been unconciously and instinctively led to that great branch of liteature in which he was destined subsequently to attain he highest eminence. But the habits thus formed, whatver influence they may have exerted on his future life, ere by no means favourable to the success of his acadeical pursuits. He was, by his own admission, exceedigly deficient in classical learning; and, in fact, he apears to have been sent to Oxford without either the prearation or the mental training necessary to enable him to eap the advantages of academical instruction. This may probably account for the harshness with which he speaks of the system pursued in the English universities, though it will neither explain nor obviate critical censures, many of which subsequent reform and improvement show to have been but too well founded. He appears to have spent at Magdalen College fourteen months, which he describes as the most idle and unprofitable in his life; but why, even with his habits of irregular application, they were so idle and unprofitable, he has nowhere informed us. Of the indifference of one of his tutors, and the almost total neglect of the other, he appears, indeed, to have had good cause of complaint; but as he admits that he was disposed to gaiety and late hours, the pupil must in justice share the blame with his masters, and cease to complain that he was not taught what he perhaps affected to despise. His objections to the system pursued, however, and his strictures on the silence of the Oxford professors, which is imperfectly supplied by the tutors of the several colleges, and by which the youth are deprived of public instruction, with all the advantages resulting from this species of institution, remain in full force, and are altogether unaffected by the personal circumstances to which we have just alluded.

When Gibbon first left Magdalen College, during the long recess between the Trinity and Michaelmas terms, his taste for reading, as he informs us, began whimsically enough to revive, and, "unprovided with original learning, unformed in the habits of thinking, and unskilled in the arts of composition, he resolved to write a book." The title of this first essay, The Age of Sesostris, was perhaps suggested by Voltaire's Age of Louis XIV.; and, what is deserving of remark, its object was not to narrate the exploits of the conqueror of Asia, but to investigate the probable date of his life and reign. On his return to Oxford, however, he abandoned this project, and the sheets he had written were afterwards committed to the flames. By the negligence of his second tutor he was now left entirely to himself, and, from want of experience, advice, and occupation, he was betrayed into culpable improprieties of conduct, ill-chosen company, late hours, and inconsiderate expense. In his peculiar frame of mind, indeed, there appears to have been originally interwoven no inconsiderable share of juvenile arrogance and presumption. Whilst his debts were growing, his studies neglected, and his frequent absences from his college visible and scandalous, the blind activity of idleness urged him into the perilous mazes of controversy, and, at the age of sixteen, he contrived to bewilder himself amidst the errors of the church of Rome.

The bold criticism of Middleton's Free Inquiry appears to have given the first shock to his Protestantism; and whilst he hovered as it were on the very verge of infidelity, the perusal of Bossuet's Exposition of the Catholic Doctrine, and his History of the Protestant Variations, seem to have recalled him from the region of doubt, and led him to seek repose in the bosom of an infallible church. These works, says he, "achieved my conversion, and I surely fell by a noble hand." In this fall, however, Parsons the Jesuit appears to have had a considerable share; for, in another part of his Memoirs, he imputes his conversion principally to that vigorous writer, who, in his opinion, had urged all the best arguments in favour of the Roman Catholic religion. But be this as it may, he had no sooner settled his new religion than he resolved to profess himself a Catholic; and, accordingly, on the 8th of June 1753, he solemnly abjured the errors of heresy before a Catholic priest in London, and immediately announced the event to his father in an elaborate controversial epistle, approved by his spiritual director. His father, though neither a bigot nor a philosopher, was astonished at his apostacy from the religion of his country; and having, in the first sally of passion, divulged a secret which prudence might have suppressed, thus shut the gates of Magdalen College against the return of his son. At an advanced age, when he had learned to treat all religions with equal indifference, Gibbon, reviewing this event of his life, speaks of it with an indulgent tenderness, which will perhaps be acknowledged as more natural than just; he avows himself proud of an honest sacrifice of interest to conscience; and he declares that he can never blush if his tender mind was entangled in the sophistry which had seduced the manly understandings of Chillingworth and Bayle. The resemblance, however, is closer in the transition which they afterwards made from superstition to scepticism; from that state of mind which believes against reason, to its opposite extreme, which attacks the foundations of reason itself, and seeks to inculcate a belief that there is no belief. "To my present feelings," says Gibbon, "it seems incredible that I should ever believe that I believed in transubstantiation."

Finding it necessary to form a new plan of education, and also to devise a method which, if possible, might effect the cure of his spiritual malady, his father, after much consideration, determined to fix him, during some years, at Lausanne, in Switzerland; and there he was accordingly established, with a very moderate allowance, under the care of M. Pavilliard, a Calvinist minister of that place. In as far as regards the instructor and guide thus selected, a more fortunate choice could scarcely have been made. From the testimony of his pupil, and the still more conclusive evidence of his own correspondence with the elder Mr Gibbon, M. Pavilliard appears to have been a man of singular good sense, temper, and knowledge of the human mind; and in the method of instruction which he adopted for the double purpose of advancing the intellectual improvement and correcting the religious aberration of his pupil, he evinced a refinement and delicacy of judgment which it is much more easy to admire than to imitate. At first, however, M. Pavilliard had a twofold obstacle to contend with; he could not speak English, and as Mr Gibbon did not understand French, some time necessarily elapsed before he could even attempt to carry into effect the instructions he had received. But when, by mutual industry, this difficulty had been in part removed, M. Pavilliard lost no time in endeavouring, by considerate and judicious kindness, to secure the attachment of his pupil; and having accomplished this object, he then directed his studies according to a regular plan, and placed within his own reach such means of information as seemed best calculated to remove the errors into which he had fallen. "My obligations to the lessons of M. Pavilliard," says the historian in his Memoirs, "gratitude will not suffer me to forget; he was endowed with a clear head and a warm heart; his innate benevolence had assuaged the spirit of his church; he was rational because he was moderate; in the course of his studies he had acquired a just, though superficial knowledge of most branches of literature; and he laboured with assiduous patience to know the character, gain the affection, and open the mind of his English pupil. As soon as we began to understand each other, he gently led me, from a blind and undistinguishing love of reading, into the path of instruction. I consented with pleasure that a portion of the morning hours should be consecrated to a plan of modern history and geography, and to the critical perusal of the French and Latin classics; and at each step I felt myself invigorated by the habits of application and method. His prudence repressed and dissembled some youthful sallies; and as soon as I was confirmed in habits of industry and temperance, he gave the reins into my own hands." On the more delicate subject of religion, M. Pavilliard followed the same winning and judicious method, with equal success; and at length, on Christmas day 1754, Mr Gibbon, after a full conviction, received the sacrament in the church of Lausanne. "It was here," says he, "that I suspended my religious inquiries, acquiescing with implicit belief in the tenets and mysteries which are adopted by the general consent of Catholics and Protestants."[1]

At Lausanne Gibbon laid the foundation of all his future improvement; and although it is no doubt true, as he has himself observed, that every man who rises above the common level has received two educations, one from his teachers and another from himself, yet it is at least equally so that the success of the second is in a great measure dependent on the proper direction given to the first. Under his judicious tutor he was reclaimed from his excursive and desultory habits of reading, and initiated in a regular and methodical course of study, without in the least abating his thirst of general knowledge, or hindering him from gratifying his curiosity, after the hours appropriated to the pursuits in which he had been led to engage. His reading had now a fixed object, the attainment of which made him sensible of the value of his acquisitions, and reconciled him to that system of regular application by which all his powers were invigorated. By acquiring a knowledge of the Greek, Latin, and French languages, new stores of learning were opened, and new models of taste presented to him. Poetry, history, philosophy, criticism, and antiquities, in their turn occupied his attention; and the honest zeal of the tutor was admirably seconded by an unwearied industry and insatiable avidity of knowledge on the part of the pupil, which bespoke a mind capable of extraordinary attainments, and deserving of the highest honours in literature. For the pursuit of science, however, he evinced neither the same aptitude nor the same inclination. His father had been desirous, and even pressing, that he should devote some time to the study of the mathematics; nor did he refuse to comply with a wish so reasonable. But, after attending during two winters the prelections of a teacher, who explained the elements of algebra and geometry as far as the conic sections of the Marquis de l'Hôpital, he relinquished for ever the pursuit of the mathematics, in which he appears to have made but little proficiency, and consoled himself with the reflection, in which few will probably be inclined to coincide, that he desisted "before his mind had become hardened by the habit of rigid demonstration, so destructive of the finer feelings of moral evidence, which must determine the actions and opinions of our lives." It is not very wonderful, perhaps, that a mind naturally disposed to doubt should shrink from certain and demonstrable truth, which excludes the play of sceptical ingenuity; or that the rigour of exact science should revolt one vho had so long been accustomed to expatiate in the more ttractive regions of taste and literature; but, on the other and, it does seem a little surprising that Gibbon, like ohnson, should have thought himself entitled to underalue a science which he had failed to acquire, and that is memory did not suggest to him many eminent examles in disproof of his assertion that the mind becomes harened by the habit of rigid demonstration. It is always asy, however, to find a plausible excuse for neglecting that hich we want either the power or the inclination to pursue.

---

[1] As Mr Gibbon was himself alone instrumental in his conversion to popery, so he seems inclined to take to himself a large share of the merit of his reconversion to protestantism. "Mr Pavilliard," says he, "was not unmindful that his first task, his most important duty, was to reclaim me from the errors of popery. The intermixture of sects has rendered the Swiss clergy acute and learned on the topics of controversy; and I have some of his letters in which he celebrates the dexterity of his attack, and my gradual concessions, after a firm and well-managed defence. I was willing, and I am now willing, to allow him a handsome share of the honour of my conversion; yet I must observe that it was principally effected by my private reflections; and I still remember my solitary transport at the discovery of a philosophical argument against transubstantiation." With reference to the claim here put forward by Mr Gibbon, Lord Sheffield observes: "M. Pavilliard has described to me the astonishment with which he gazed on Mr Gibbon standing before him; a thin little figure, with a large head, disputing and urging, with the greatest ability, all the best arguments that had ever been used in favour of popery." Bossuet and Parsons had supplied him with his arms.

Whilst at Lausanne, Gibbon to his classical attainments dded the study of Grotius and Puffendorff, of Locke and Iontesquieu; and he also mentions the Provincial Leters of Pascal, the Life of Julian by La Bleterie, and the ivil History of Naples by Giannone, as having remotely ontributed to form the historian of the Roman empire. rom the Provincial Letters he tells us that he learned o manage the weapon of grave and temperate irony, even n subjects of ecclesiastical solemnity; a weapon, we may emark, which, however useful to a polemic, is unlawful in he hand of an historian, and which, when resorted to by he latter, justly subjects him to the suspicion of having xhausted both his courage and his argument. Truth as vell as error may be discredited by a sneer, which it is proerbially impossible to refute; sarcasm may provoke ridiule and excite contempt, but it can never conduce to the urposes of that sound practical philosophy which seeks s examples in history. It is more to the honour of our ndefatigable student that, about this time, he established correspondence with several distinguished literary chaacters, to whom he looked for instruction and direction; ith Crevier, the successor of Rollin, and the editor of ivy; with Breitenger of Zurich, the editor of a Septugint Bible; with Professor Matthew Gesner of Göttinen, and M. Allamand, minister at Bex;—and that by the cuteness of his remarks, the extent of his knowledge, nd his zeal in the cause of literature, he attracted their articular attention, and proved himself not unworthy of heir confidence.

He had also the satisfaction of seeing Voltaire, who, fter forfeiting by his own misconduct the friendship of he king of Prussia, had retired, at the age of sixty, ith a plentiful fortune, to this free and beautiful couny, and resided two winters at Monrepos, a countryouse close to a suburb of Lausanne. "The most extrardinary man of the age" received the young Englishman ith civility, but without any peculiar notice or distincon. *Virgilium vidi tantum*, says Gibbon. But the inense with which the autocrat of literature was then aproached, and the boyish enthusiasm of the unfledged auhor, which made him look upon admission to the private heatricals of Monrepos as the highest distinction, could carcely be without influence on the formation of his chaacter and opinions. According to his own expression, e then rated Voltaire above his real magnitude; but he as probably unconscious that both his tone of mind and is manner of expression, in which he was ever endeaouring to point his stately and inflexible English with he light and graceful irony of the Frenchman, were peretually betraying his early adoration of the patriarch; hilst, on the other hand, Voltaire little suspected that, n the awkward and oddly-formed English boy (whose nemory had retained, and whose indiscretion made pubc, one of his fugitive poems not yet intended for the ulgar ear), he was silently forming, not a disciple, but a ellow-labourer, whose fame would at length cast his own istorical reputation into the shade. The immediate effect f Mr Gibbon's attendance at the private theatre of Monepos was an increased predilection for the French stage, nd a corresponding decline in his veneration for Shakpeare. A taste formed to delight in the smooth-shaven, artificial lawn of a French play, can never retain any relish for the wild, irregular, masculine beauties of our great dramatist, heaped together as they are with all the profusion, magnificence, and simplicity of nature herself.

Gibbon was now familiar in some, and acquainted in many families of Lausanne, and his evenings were generally devoted to conversation and cards, either in private parties, or in what are called assemblies; in short, he enjoyed his full share of the amusements of society. During this alternation of study and pleasure, he became enamoured of Mademoiselle Susan Curchod, daughter of the minister of Crassy, in the mountains which separate the Pays de Vaud from the county of Burgundy; a young lady whose personal attractions were, he assures us, embellished by the virtues and talents of the mind. His addresses were favoured by Mademoiselle Curchod and her parents, and both at Crassy and at Lausanne he indulged his dream of felicity; but his father, on being consulted, expressed the utmost repugnance to "this strange alliance," and his son, thinking more of his prospects than of his passion, yielded, as he says, to his fate. "I sighed as a lover," he adds; "I obeyed as a son." His wound, which could scarcely have been deep, was insensibly healed by time, absence, and the habits of a new life; and his cure was accelerated by learning that the lady herself was not inconsolable for the loss of so prudent a lover. But the minister of Crassy soon afterwards died, and as his stipend died with him, his daughter retired to Geneva, where, by teaching young ladies, she earned a hard subsistence for her mother and herself. In her lowest distress, however, she maintained a spotless reputation, and having attracted the notice of a rich banker of Paris, a citizen of Geneva, she became the wife of M. Neckar, afterwards prime minister of France.

In 1758, Mr Gibbon took leave of Lausanne, and returned to England, after an absence of nearly five years. His father received him as a man and a friend, and appeared to rejoice in the success of the plan of education which had effected the reconversion and improvement of his son. One disagreeable circumstance, however, awaited the young student on his return to his native country and paternal home. In the room of her who had given him birth he found a stepmother, whom he regarded as an intruder, and to whom he was introduced with the most unfavourable prejudice. But this initial dislike, by no means unnatural on his part, was soon overcome by the amiable manners and obliging conduct of the new Mrs Gibbon, who gave him a polite welcome, and did all in her power to study and gratify his wishes. At home he was allowed to consult his own taste in the choice of place, company, and amusements; and his excursions were bounded only by the limits of the island and the measure of his income. He assiduously frequented the theatre at a very propitious era of the stage, and indulged somewhat freely in the pleasures of a town life; but the better habits which he had formed at Lausanne, prevailing over these occasional excesses, induced him to seek more elegant and rational society, though, in the first instance, not with the success which might have been expected. He had now reached his twenty-first year without having made choice of a profession, or engaged in any regular employment. His stepmother recommended the study of the law, and some faint efforts were made to procure for him the situation of secretary to a foreign embassy; but the former scheme he declined, and the latter did not succeed.

Of the first two years which he spent in England, he passed about nine months in London, and the remainder in the country. But as his father's taste had always preferred the highest and the lowest company, for which, it seems, he was equally qualified, he was by this time forgotten by the great with whom he had associated; and, as he had no fixed residence in London, his son failed to gain admission into those circles of society in which he ardently desired to move. He acquired an intimacy, however, in the house of David Mallet, and by his means was introduced to Lady Harvey's parties; nor was he at all displeased by her preference and affectation of the manners, language, and literature of France. But his progress in the English world was in general left to his own efforts, and those efforts, he says, were languid and slow. The want of society, however, does not appear to have given him much uneasiness; he depended chiefly on himself for his happiness; and, unlike many of his countrymen, he knew not the tediousness of an idle life, or the misery of having hours which he could not occupy. At Buriton he enjoyed many opportunities of adding to his stock of learning; books became more and more the source of all his pleasures; and the leisure he could borrow from his systematic plan of study was employed in perusing the works of the best English authors since the revolution. His father had endeavoured in vain to inspire him with a taste for agriculture, and to induce him to acquire a knowledge of rural affairs; but his own more rational object was to restore the purity of his diction which had been corrupted by the long and constant use of a foreign idiom. By the advice of Mallet he was directed to the writings of Swift and Addison, which he has on the whole judiciously discriminated. "Wit and simplicity," says he, "are their common attributes; but the style of Swift is supported by manly original vigour; that of Addison is adorned by the female graces of elegance and mildness." But the first productions of Robertson and Hume, the histories of Scotland and of the Stuarts, engaged his attention still more deeply. The perfect composition, the nervous language, and the well-turned periods of the one, inflamed him with the ambitious hope that he might one day tread in his footsteps; whilst the calm philosophy and the careless inimitable beauties of the other often forced him to close the volume with a mixed sensation of delight and despair. Charmed, however, as he was with Swift and Addison, with Robertson and Hume, and well as he knew how to appreciate the peculiar excellencies of their respective styles, he lost sight of every model when he became a writer of history, and formed a style of his own, which, though in its essential spirit it is at least in part French, is justly entitled to be considered as original.

In 1761, Gibbon, yielding to the authority of a parent, published his *Essai sur l'Etude de la Littérature*, which appeared in a small volume duodecimo. As his object, at this time, was to get an appointment as secretary of legation to some English ambassador or plenipotentiary, his father believed that the proof of some literary talents might introduce him to public notice, and second the recommendation of his friends; and, with these views, the essay in question was published. Part of this production had been written at Lausanne, and the remainder completed in London, where the whole was revised by Dr Maty, author of the *Journal Britannique*, who approved the design, and applauded the execution. The object of the essay was to prove, in opposition to D'Alembert and other writers in the *Encyclopédie*, that all the faculties of the mind may be exercised and displayed in the study of ancient literature, and that the new philosophy for which the *Encyclopédistes* contended was not more adverse to the cultivation of taste than inconsistent with the principles of enlightened reason. But he introduces a variety of topics not immediately bearing on his design, and shows that, in the belles-lettres and in criticism, he had expatiated through a range much more ample than could have been expected from his years. The work, indeed, is remarkable, both for the ideas which it contains, and for the purity with which it is written in French, a language then more familiar to Gibbon than his own. This book, however, made less sensation in England than in France, where it was most favourably received, and, by anticipation, ensured the author, particularly amongst men of letters, the most distinguished reception. In England it was received with cold indifference, little read, and speedily forgotten; but had the knowledge of the French language been then as common in the literary world as it is now, so extraordinary a production from the pen of a young man would have met with a different reception, and raised high expectations of future eminence. For the neglect of his countrymen, however, the author was in some measure indemnified by the copious extracts, the warm commendations, and the flattering predictions, of the journals of France and Holland, countries where the work was estimated at its real value. In his Memoirs he discusses its merits and defects with singular impartiality; but, in fixing the respective measures of praise and blame, the former predominates, and with justice.

The uncongenial profession of a militia captain, which was embraced by Gibbon about the time when this essay appeared, neither diverted his mind from his historical pursuits, nor relaxed his unwearied industry. It is true, that for two years and a half he endured a "wandering life of military servitude" in the south battalion of the Hampshire militia; but though the roll of the drum disturbed him in the midst of an inquiry into ancient weights, measures, and coins, even these days of more than usual bodily activity and mental distraction were turned to account. In his marchings and countermarchings from Winchester to Blandford, and from Blandford to Southampton, he studied the *Mémoires Militaires* of M. Guischardt;—the discipline and movements of a modern battalion gave him a clearer notion of the phalanx and the legion;—and, amidst his peaceful evolutions, the captain of the Hampshire grenadiers laid in that store of military knowledge which afterwards enabled him successfully to elucidate the campaigns of Julian, of Belisarius, and of Narses. At the peace of 1763 his regiment was disbanded, and he resumed his studies, the regularity of which had suffered unavoidable interruption during the period of his service in the militia. In forming a new plan, he hesitated for a time between the mathematics and the Greek language, both of which he had neglected since his return from Lausanne; but having at length given the preference to Greek, he applied himself to Homer, and pursued his reading with unflinching vigour. Whatever he read or studied, however, appears to have had reference, directly or indirectly, to historical composition. From the early age of fifteen, when he projected writing the Age of Sesostris, this seems to have been the grand aim of all his studies; and, in fact, he aspired to the character of an historian long before he was able to fix upon a subject. Nor was the time unfavourable to his ambition, or calculated to abate his ardour. On the contrary, a generous emulation was excited by witnessing the triumphs of Robertson and Hume; and it is not improbable that, whilst he secretly aspired to complete the triumvirate of British historians, he thought that a subject only was wanting to enable him to realise the object of his ambition.

During his life of military servitude, as he calls it, he had resolved on several subjects for historical composition, which, from their diversity and dissimilarity, prove that he had then no particular purpose to serve, no preconceived theory to support, no actual prejudice or belief to overthrow. Amongst these he has enumerated, 1. the expedition of Charles VIII. of France into Italy; 2. the crusade of Richard *Cœur de Lion;* 3. the barons' wars against John and Henry III.; 4. the history of Edward the Black Prince; 5. the lives, with comparisons, of Henry V. and the Emperor Titus; 6. the life of Sir Philip Sidney; and, lastly, that of "Scotland's Montrose;" all of which he sucessively chose and rejected. He then fixed on Sir Wal-er Raleigh as his hero; but, after dwelling with fondness n his eventful story, varied by the characters of the sol-ier and sailor, the courtier and historian, he abandoned his esign. "What new lights," he asks, "could I reflect on subject which has exercised the accurate industry of irch, the lively and curious acuteness of Walpole, the ritical spirit of Hurd, the vigorous sense of Robertson, nd the impartial philosophy of Hume?" The History of e Liberty of the Swiss, and the History of the Repub-c of Florence under the House of Medicis, were each in rn meditated and discarded.

But whilst his brain was teeming with projects, which ame like shadows and so departed, all his designs were spended by a visit to the Continent, which, according the law of custom, if not of reason, his father thought ecessary to complete his education. Having obtained om Lady Harvey, Horace Walpole, Mallet, and the uke of Nivernois,[1] letters of recommendation to various ersons of distinction in France, he left his father's resi-ence in Hampshire, and reached Paris on the 28th of nuary 1763, only thirty-six days after the disbanding of e militia. Two years were loosely defined as the term his absence; and he was left at liberty to spend his me in such places and in such a manner as might be ost agreeable to his own taste and judgment. In France e fame of his *Essai sur l'Etude de la Littérature* had pre-eded him, and his vanity was gratified by being consider-l as an Englishman of fortune who merely wrote for his nusement. When Gibbon reached Paris, Montesquieu d Fontenelle were no more; Voltaire had retired to his tate near Geneva; Rousseau had been driven from his ermitage of Montmorency; and he neglected to seek the quaintance of Buffon. But he mixed in familiar society ith D'Alembert, Diderot, the Count de Caylus, the Abbé la Bléterie, Barthélemy, Raynal, Arnaud, Condamine, uclos, Bougainville, Caperonnier, De Guignes, Suard, d others; and four days in the week he had a place ithout invitation at the hospitable tables of Mesdames eoffrin and Du Boccage,[2] of Helvetius, and Baron d'Hol-ich. After passing fourteen weeks at Paris, enjoying the ciety and amusements of that capital, he, in the month of ay 1763, revisited his old friends at Lausanne, where he remained nearly a year. During this sojourn on the banks of the Leman Lake, he formed an acquaintance, destined to ripen into lasting friendship, with Mr Holroyd, afterwards Lord Sheffield, who at a subsequent period became as it were the guardian of his posthumous fame, and whom he characterises as "a friend whose activity in the ardour of youth was always prompted by a benevolent heart and a strong understanding." In 1764 he set out for Italy, after having carefully studied the geography and ancient history of the seat of the Roman empire, with the view of rendering his visit profitable and satisfactory to his own mind. His description of his journey is clear and precise; and as he possessed a temper not very susceptible of enthusiasm, he scorns to affect raptures which he did not feel. But the sight of Rome appeared to have conquered his apathy, and as he approached and entered the eternal city, his mind was agitated with emotions which he declares it impossible either to forget or express. Here the conception of the work which was destined to fix and perpetuate his fame first rose in his mind. "It was at Rome," says he, "on the 15th of October 1764, as I sat musing amidst the ruins of the Capitol, while the bare-footed fryars were singing vespers in the Temple of Jupiter [now the church of Zocolants or Franciscan friars] that the idea of writing the decline and fall of the city first started to my mind."[3] But this appears to have been merely the effect of the emotion produced by local associations; for the original plan was confined to the decay of the city rather than of the empire. Rome and Italy having satiated his curiosity, he returned to England, and arrived at his father's residence in the month of June 1765.

The five years and a half which intervened between his return from his travels and the death of his father in 1770, seem to have formed the portion of his life which he passed with the least enjoyment, and remembered with the least satisfaction. By the resignation of his father, and the death of Sir Thomas Worsley, he was successively promoted to the rank of major and lieutenant-colonel commandant of his regiment of militia; but he was each year more disgusted with "the inn, the wine, the company, and the tiresome repetition of annual attendance and daily exercise." He had other and more rational grounds of uneasiness on account of his situation. He belonged to no profession which he could cultivate; he had adopted no plan, by which, like some of his acquaintance, he might rise to consequence. Without aim or pursuit, he lamented that he had not engaged in the study of the law, embarked in trade, tempted the chances of civil office or India adventure, or at least courted "the fat slumbers of the church." But a mind like his was not formed to remain inactive, and the dissatisfaction which he now experienced in considering his actual position, probably arose from an impatience to acquire fame, and the elongation of the only prospect which had presented itself to his view. He still contemplated, at an awful distance, a history of the decline and fall of Rome; but, as an immediate object of pursuit, he resumed the study of the revolutions of Switzerland, which he had formerly abandoned, and, after much reading, executed, in French, the first book of a history of Swiss liberty. This specimen of his work was read, in the winter of 1767, to a literary society of foreigners in London; and as the author was unknown, he listened without observation, though with painful sensations, to the free strictures and unfavourable sentence of his judges; but their condemnation, he assures us, was ratified by his cooler thoughts. The attempt, however, was generously commended by Mr Hume, to whom the manuscript had been submitted, and who endeavoured only to dissuade the author from composing in French, and thus, as Horace says of the Romans who wrote in Greek, carrying faggots into the wood. The design was, however, abandoned, in deference to the opinion of the foreign critics, and the manuscript subsequently passed into the hands of Lord Sheffield.

---

[1] In acknowledging the politeness of the Duke of Nivernois, Gibbon notices a circumstance which serves in some degree to unfold s own character, and also to exhibit that superiority of pretension, from which, in fact, he never departed. "The Duke," says he, received me civilly, but, perhaps through Maty's *fault*, treated me more as a man of letters than as a man of fashion." Congreve d Gray were weak enough to be offended on account of a similar mistake; but that Gibbon, whose sole ambition was to rise to lite-ry eminence, should have for a moment preferred the equivocal character of a man of fashion to that of a man of letters, is as unac-untable as it is surprising that, at an advanced period of life, he should have deliberately recorded such an incident. If he had been ly a man of fashion, the reader would in vain have sought for his biography in the Encyclopædia Britannica.

[2] Gibbon was also introduced to Madame du Deffand, on whom he appears to have made, upon the whole, a favourable impression. it his elaborate efforts to be agreeable, and to assume the perfect tone of French society and manners, did not escape that clever d fastidious woman, whom Voltaire so justly called *l'aveugle clairvoyante*. In one of her letters to Walpole, she writes thus: "As M. Gibbon, he is a very sensible man, who has a great deal of conversation, an infinity of knowledge, you will perhaps add, an in-ity of cleverness (*d'esprit*)—I am not quite decided on that point. He sets too much value on our talents for society (*nos agrêments*), ows too much desire of acquiring them; it is constantly on the tip of my tongue to say to him, 'Don't put yourself to so much uble; you deserve the honour of being a Frenchman.'"

[3] In a memoir of the life of Gibbon, prefixed to Guizot's French edition of the Decline and Fall, and written by M. Suard, the nslator of Robertson, to whom the historian was intimately known, we meet with the following observations on the passage above oted: "Perhaps it will not be difficult to trace, in the impressions from which the conception of the work arose, one of the causes that war which Gibbon seems to have declared against Christianity; the design of which neither appears conformable to his cha-cter, little disposed to party-spirit, nor consistent with that moderation of thought and sentiment which led him in all things, rticular as well as general, to view the advantages as well as the injurious consequences. But, struck with a first impression, bbon, in writing the history of the fall of the empire, saw in Christianity only an institution which had placed vespers, bare-ted friars, and processions, in the room of the magnificent ceremonies of the worship of Jupiter and the triumphs of the Capi-." This explanation, however, seems to us entirely fallacious. In many of his habits Gibbon was at least half a Frenchman; t he was not the creature of such impressions as that which M. Suard has here attributed to him. He drew his aversion to Chris-nity from a deeper source. Paganism was the old established religion; Christianity, viewed in its origin and early history, was a ring innovation. The one was sanctioned by time and confirmed by habit; the other had nothing but its truth to recommend it. this light Gibbon viewed the two religions, as he has himself unequivocally declared in one of his letters; his principles naturally l him to recognise the prescriptive rights of paganism, which he regarded as the established system; and they also indisposed him wards Christianity, which sought to effect and ultimately accomplished its subversion. The conservative character of his political ed attached him to the former; but he hated the latter both as a politician and as an unbeliever. This seems to be the whole stery.

After this failure, Gibbon, in 1767, united with M. Deyverdun, a native of Lausanne, then in England, and a person of taste and critical discernment, to whom he was much attached, in publishing a literary journal, under the title of *Mémoires Littéraires de la Grande Bretagne*, in imitation of Dr Maty's *Journal Britannique*, which was esteemed and regretted. But the attempt met with little encouragement, and only two volumes of the *Mémoires* appeared. Gibbon acknowledges having reviewed, in the first volume, Lord Lyttleton's *History of Henry II.*, a work of sense and learning, but not illuminated by a single ray of genius. The materials of a third volume were nearly completed, when Deyverdun having accepted the situation of travelling companion to Sir Richard Worsley, to which his coadjutor had recommended him, this appointment put an end to the *Mémoires Litteraires.*

Gibbon's next performance was of a bolder description, being nothing less than an attack on Warburton, who, in a singular chapter of the Divine Legation of Moses Demonstrated, had maintained that the descent of Æneas and the Sybil to the infernal regions was not a false, but a mimic scene, representing the initiation of Æneas, in the character of a lawgiver, into the Eleusinian mysteries. This hypothesis, which the bishop had endeavoured to support by an elaborate but strained interpretation, Gibbon assailed and completely overthrew in his Critical Observations on the Sixth Book of the Æneid, published in 1770. In this production he proved that the ancient lawgivers did not invent the mysteries, and that Æneas was never invested with the office of lawgiver;—that there is not any argument or circumstance which melts a fable into allegory, or removes the scene from the Lake Avernus to the Temple of Ceres;—that such a wild supposition is equally injurious to the poet and the man;—that if Virgil was not initiated, he could not, and if he were, he would not, reveal the secrets of the initiation;—and that the anathema of Horace (*Vetabo qui Cereris sacrum vulgarit*, &c.) at once attests his own ignorance, and the innocence of his friend. All this, which seems quite conclusive against Warburton's allegorical interpretation, might, however, have been argued in temperate and respectful language; but the clear, elegant, and decisive criticism of Gibbon, which early received the approbation of Heyne, and has since been generally acknowledged to be unanswerable, was deformed by an acrimony of style which might be excused, but could scarcely be justified, by the pride and presumption with which the bishop pronounced his infallible decrees, and the merciless severity with which he lashed his antagonists in his polemical writings.[1] A calmer tone would have been better suited to the subject; and the argument gained nothing in force by the circumstance, that the author aimed his strokes against the person and the hypothesis of Bishop Warburton. At the same time "the dictator and tyrant of the world of literature" maintained a discreet silence; he had previously shrunk from the encounter (which he had himself provoked) with Dr Lowth; and Gibbon appears to have been, in like manner, considered as an antagonist with whom it might be hazardous openly to do battle.

In the fifteen years which elapsed between the publication of his *Essai sur l'Etude de la Littérature*, and that of the first volume of the *Decline and Fall of the Roman Empire*, this criticism on Warburton, and some articles in the journal above mentioned, were the only productions of his pen which Gibbon gave to the world. But after the death of his father in 1770, an event which left him the entire disposal of his time and choice of his pursuits, he applied himself seriously to the composition of the first volume of his history. For several years he had revolved the subject in his mind, and read a great deal with a view to the undertaking, including the classics as low as Tacitus, Pliny the younger, and Juvenal; the Augustan history, and the original records both Greek and Latin, from Dion Cassius to Ammianus Marcellinus; the Annals and Antiquities of Muratori, which he compared with Sigonius and Maffei, Baronius and Pagi; the Theodosian Code, with the commentary of James Godefroy; besides all that related to the propagation of the gospel and the triumph of the church, the narratives and apologies of the Christians themselves, and the Jewish and heathen testimonies, as these have been collected and illustrated by Lardner. Observing the maxim, *Multum legere potius quam multa*, he reviewed again and again the French and English, as well as the Latin and Italian classics; his Greek studies, though less assiduous, maintained and extended his knowledge of that incomparable language; and a third perusal of Blackstone's *Commentaries*, with a copious and critical abstract, formed an introduction to the knowledge of English jurisprudence. At the commencement of his undertaking all was dark and doubtful—even the title of the work, the true era of the decline and fall of the empire, the limits of the introduction, the division of the chapters, and the order of the narrative; and, amidst the uncertainty in which he found himself involved, he was often tempted to cast away the labour of seven years. But, happily, in spite of every discouragement, he persevered in his task, which his return as member of parliament for the borough of Leskeard, in 1775, did not seriously interrupt; and, on the 17th of February 1776, he gave to the world the first volume of that work which has placed its author in the foremost rank of modern histoians. Its success was almost unprecedented. The first impression was exhausted in a few days; a second and even a third edition were scarcely adequate to the demand; he book was on every table, almost on every toilette; nd, to use his own words, the historian was crowned by he taste or fashion of the day. But, if the voice of public favour be music to the ear of an author, Gibbon must have derived more substantial satisfaction from the approbation of such judges as Robertson and Hume. “The candour of Dr Robertson,” says he, “embraced his disciple. A letter from Mr Hume overpaid the labour of en years.” The latter, however, with his usual sagacity, anticipated the objections which he foresaw would be urged against the fifteenth and sixteenth chapters. “When I heard of your undertaking, which was some ime ago,” says he, “I own I was a little curious to see how you would extricate yourself from the subject of your wo last chapters. I think you have observed a very prudent temperament; but it was impossible to treat the ubject so as not to give grounds of suspicion against you, nd you may expect that a clamour will arise. This, if ny thing, will retard your success with the public; for, n every other respect, your work is calculated to be popular. But, among many other marks of decline, the prevalence of superstition in England prognosticates the fall f philosophy and decay of taste; and though nobody be more capable than you to revive them, you will probably and a struggle in your first advances.”

---

[1] Hayley, a poet and a scholar, not only pronounces a favourable judgment on the critical observations, but even condescends to justify an acrimony of style, which the author himself afterwards regretted as unmanly and indefensible. Heyne, more learned, and at the same time more candid, gently blamed the contemptuous treatment of a man who, with all his faults, was entitled to the esteem of every scholar. "*Paullo acrius quam velis......perstrinxit.*" We may add, that the editor of the Warburtonian tracts, Dr Parr, considers the allegorical interpretation "as completely refuted in a most clear, elegant, and decisive work of criticism, which could not derive authority from the greatest name, but to which the greatest name might with propriety have been affixed."

Gibbon's own reflections on this subject appear to us to be either hypocritical or ironical. He affects not to have believed that the majority of English readers were so fondly attached even to the name and shadow of Christianity; and he professes that if he had foreseen that the pious, the timid, and the prudent, would feel, or affect to feel, with such xquisite sensibility, he might perhaps have softened the wo invidious chapters, which were calculated, he admits, o create many enemies, and to conciliate few friends. But as the shaft was shot and the alarm sounded, he conoled himself with the reflection, that if the voice of the priests was clamorous and bitter, their hands were disarmed from the power of persecution. The sincerity of this pology is more than doubtful; nor is it possible to believe hat Gibbon completely misjudged the state of the public eeling on the subject of Christianity, which Hume appears, from the above extract, to have so accurately appreciated. But, however this may be, the effect of Gibon's hostility towards Christianity, upon the character of is history, has, for the first time, been fairly and justly stimated by the French critics. What they complain of is not so much his insidious description of the human means by which it was propagated, as his false estimate f its influence upon the social and even political condition f mankind. In this country, the matter has chiefly been onsidered in a polemical spirit; abroad, it has been viewd in a light at once more enlarged, more philosophical, nd, we may add, more wisely Christian. Here, amidst he indignation of the better part of the community at he publication of the first volume of the Decline and Fall, ur more distinguished theological writers stood aloof, nd the onset was made by a few rash and feeble volunteers, who, ill armed and worse disciplined, rushed against he thick bosses of the historian's buckler. With a single discharge of his formidable artillery of learning and sarcasm, Gibbon laid prostrate the whole disorderly squadron; and Davis, Chelsum, Travis, and the rest, sunk back into their original insignificance. When the first of these ventured to attack, not the faith, but the fidelity of the historian, the latter published his Vindication, which, “expressive of less anger than contempt, amused for a moment the busy and idle metropolis,” and annihilated Davis.

Their plan of attack, indeed, was as misjudging as their mode of conducting it was unskilful. With a little learning scraped together for the occasion, they ventured to impeach the accuracy and to condemn the false quotations of a scholar, whose mind was thoroughly saturated with every kind of knowledge which could bear upon his subject; and they could only make up in vituperation and intemperance for their manifest deficiency in all the qualifications requisite in defenders of Christianity. Watson, bishop of Llandaff, was the only one of the number who had the good taste to maintain towards his adversary the dignified courtesy which belonged to his literary character; and the judgment to confine his Apology to one point, namely, the inadequacy of Gibbon's secondary causes to account for the diffusion of Christianity. But it may even be questioned whether Watson himself has not unconsciously been seduced, by the consummate skill of his antagonist, to advance beyond the position which is really impregnable, and to carry on the contest upon ground far less advantageous. The art of Gibbon consists in confounding the origin and apostolic propagation of the new religion with its later progress. No argument for the divine authority of Christianity has been urged with greater force, or developed with higher eloquence, than that which is deduced from its primary development and rapid extension throughout the greater part of the Roman empire. But this argument, unanswerable when confined within just limits, becomes feeble, or disputable, or evanescent, as we recede from the time and place where the new religion was born and first manifested to the world. By Gibbon, however, the main question, namely, the divine origin of Christianity, was dexterously eluded or speciously conceded. His plan enabled him to commence his account, in most parts, below the apostolic times; and it was only by the strength of the dark colouring which he worked, with infinite art and skill, out of the failings and follies of the succeeding ages, that a shadow of doubt or suspicion was thrown back upon the primitive period of Christianity. “The theologian,” says he, “may indulge the pleasing task of describing religion as she descended from heaven, arrayed in her native purity; a more melancholy duty is imposed on the historian: he must discover the inevitable mixture of error and corruption which she contracted in a long residence upon earth among a weak and degenerate race of beings.” This passage betrays the whole secret of his art. Divest it of the latent sarcasm which pervades the whole disquisition, and it might commence a Christian history, written in the genuine spirit of Christian candour. But as the historian, with seeming respect, yet dexterously confounding the true limits of the question, contrives to insinuate that the supposed origin of our religion is a mere Utopian dream of the theologian, and to suggest rather than affirm that the days of Christian purity were a kind of poetic golden age; so the theologian, by adventuring too far into the domain of the historian, may find himself obliged to contest points where he has little chance of victory, to deny facts established by unimpeachable evidence, and to retire, if not with the shame of defeat, at least with doubtful and imperfect success.[1]

---

[1] Gibbon speaks of his assailants with unmeasured contempt; and, in truth, he had every reason to do so. Davis, Chelsum, and Travis vanished before him; but “a victory over such antagonists was a sufficient humiliation.” If the strength of his adversaries

Nearly two years elapsed between the publication of the first and the commencement of the second volume of the history. During this interval Gibbon studied a course of anatomy, demonstrated by Dr Hunter; dived deeply into what he calls the mud of the Arian controversy; studied the transactions of the age of Constantine; and spent some months of pleasure at Paris. The prosecution of his task was also checked by employment of a different description, for which his talents were considered as peculiarly adapted. At the request of Lord Chancellor Thurlow, and Lord Weymouth, then secretary of state, he was induced to prepare an answer to a manifesto which the French court had issued against Great Britain, preparatory to a declaration of war. This Mr Gibbon accomplished with great ability, and vindicated the justice of the British arms, in a *Mémoire Justificatif*, composed in French, which, having been first approved of by the cabinet ministers, was then delivered as a state paper to the courts of Europe. For this service he was appointed one of the lords commissioners of trade and plantations; a place, the duties of which were by no means arduous, whilst it enlarged his private income by a clear addition of between L.700 and L.800 a year. His acceptance of this appointment provoked some of the leaders of opposition, and he was accused of deserting a party in which he declares he had never enlisted. On this subject, however, there is an awkward reminiscence preserved in the handwriting of Mr Fox. That statesman, in an autograph note on his copy of Gibbon's history, says, that, at the time of the declaration of war against Spain, in the year 1779, the author of this work declared publicly, at Brookes', that there would be no hope for England, except by cutting off six heads in the cabinet council, and exposing them, as an example, in open parliament; yet, before fifteen days had elapsed, he accepted a place under the same administration. The inconsistency which this statement involves, Lord Sheffield has attempted to palliate, if not to obviate, by observing, that, though his friend may have carelessly used strong expressions respecting some or perhaps all parties, yet he never meant that such expressions should be taken literally. But the world were not obliged to understand that, on political subjects, Mr Gibbon spoke in parables.

At the general election in 1780 he lost his seat for Leskeard, which had suddenly been converted into an opposition borough; and in the interval of his senatorial life which followed, he published the second and third volumes of his history. They appeared in April 1781, and excited as much attention as, though far less controversy than, his first volume. They were written with equal elegance but more caution, and exhibited proofs of juster and more profound thinking. His affection for his work did not permit him to estimate truly the reception with which these volumes were honoured; and, in his Memoirs, he speaks of a coldness, and even prejudice, which appear to have been altogether imaginary. It is certain, indeed, that their merit was fully appreciated, both at home and abroad; but two volumes are not so speedily sold as one, and the promise of a continuation, whilst it gratified his admirers, necessarily suspended that final judgment upon which the fame of the work was ultimately to depend.

Soon after the meeting of the new parliament, he was chosen, upon a vacancy, to represent the borough of Lymington in Hampshire. But the administration to which he had attached himself was now on the decline; the minister who refused to bend was broken by the tempest which had arisen against the supporters of the American war, and with his fall the board of trade was abolished, by which means our author was stripped of a convenient salary, which he had enjoyed about three years. Amidst the conflict of parties which followed the dissolution of Lord North's administration, Gibbon, from a principle of gratitude, adhered to the coalition, and his vote was counted in the day of battle (it was all he could supply), but he was forgotten in the division of the spoil. The board of trade could not be restored; a seat at the board of customs or excise was promised on the first vacancy, but the chance was distant and doubtful; the tumult of London, and the attendance on parliament, were grown irksome to him; and, without some additional income, he could not prudently maintain the style of expense to which he had for some time been accustomed. In these circumstances, and having always cherished a secret wish that the school of his youth might become the retreat of his declining age, he once more turned his thoughts to his beloved Lausanne. But before proceeding with the remainder of the narrative, we shall stop for a moment to review the historian's political career.

Gibbon entered the House of Commons in 1764, and he witnessed a great epoch in the history of the British parliament. Never had a more brilliant constellation of talent and genius risen in the political horizon; never had higher interests commanded attention and inspired eloquence. The insurrection of the colonies, the violent and arbitrary laws which had oppressed and driven them to

---

had, however, been in proportion to their numbers, he would certainly have been overwhelmed. The following is a list of the principal writings called forth by his bold yet insidious attack on Christianity:—1. Remarks on the two last Chapters of Mr Gibbon's History. 2. An Apology for Christianity, by R. Watson, D. D., Professor of Divinity in the University of Cambridge, 1776, in 12mo. 3. The History of the Establishment of Christianity, by William Salisbury, B. D., 1776, in 8vo. 4. Reply to the Reasonings of Mr Gibbon in his History, by S. Loftus, Dublin, 1778, in 8vo. 5. Letters on the Prevalence of Christianity, by East Apthorpe, M. A., 1778, in 8vo. 6. An Examination of the Fifteenth and Sixteenth Chapters of Mr Gibbon's History, by H. E. Davis, B. A., Oxford, 1778, in 8vo. 7. Remarks on the History of the Decline and Fall of the Roman Empire, by a Gentleman. 8. Remarks on the two last Chapters of Mr Gibbon's History, by James Chelsum, D. D., Oxford, 1778, in 8vo. This last was a second edition of the anonymous Remarks mentioned in the first article, and contains additional strictures by Dr Randolph, professor of divinity at Oxford. Mr Gibbon now published his answer, which appeared under the title of a Vindication of some Passages in the Fifteenth and Sixteenth Chapters of the History of the Decline and Fall of the Roman Empire, by the author, 1779, in 8vo. This was immediately followed by, 1. A Short Appeal to the Public, by the gentleman who is particularly addressed in the postscript of the Vindication, 1779–1780, in 8vo. 2. A Reply to Mr Gibbon's Vindication, by H. E. Davis, Oxford, 1780, in 8vo. 3. A Reply to Mr Gibbon's Vindication, by James Chelsum, D. D., 1785, in 8vo. The most considerable of the works directed against the History generally were, 1. Thoughts on the nature of the Grand Apostacy, with reflections and observations on the Fifteenth Chapter of Mr Gibbon's History, by H. Taylor, 1781–1782, in 8vo. 2. Gibbon's Account of Christianity considered, by Joseph Milner, A. M., 1781, in 8vo. 3. Letters to Edward Gibbon, Esq. in defence of the authenticity of the 7th verse of the fifth chapter of the First Epistle of St John, by George Travis, A. M., 1784, in 4to. 4. An Inquiry into the Secondary Causes which Mr Gibbon has assigned for the rapid growth of Christianity, by Sir David Dalrymple, Lord Hailes, 1786, in 4to. Dr Priestley, in his History of the Corruptions of Christianity, also threw down his gauntlet to Mr Gibbon, who, however, declined the challenge in a letter, exhorting his opponent to enlighten the world by his philosophical discoveries, and to remember that the merit of his predecessor Servetus is now reduced to a single passage, indicating the smaller circulation of the blood through the lungs. Of all his antagonists, Dr Watson is the only one of whom Gibbon speaks with respect, and, indeed, almost the only one who deserved it. "Let me frankly own," says he, in concluding an account of his chief opponents, "that I was startled at the first discharge of ecclesiastical ordnance; but as soon as I found that this empty noise was mischievous only in the intention, my fear was converted into indignation; and every feeling of indignation or curiosity has long since subsided into pure and placid indifference."

spair, the war with America, the misfortunes and re- rses of that ill-fated contest, the dismemberment which reatened the empire, together with the justice, policy, d necessity of concluding a peace; such were the sub- cts then debated in parliament, with an ardour, abi- y, and eloquence, not surpassed, perhaps never equalled, any other period of our history. But amidst all the citement and animation of such a scene, Gibbon re- ained mute, and threw his silent vote into the scale of wer in support of the pretensions of the crown against e opinion of the great body of the nation, and the just aims of the Americans. He thought, or professed to ink, the cause of the government, in this instance, the use of England, and declared himself more and more nvinced that the administration had the right as well as e power on their side. With a temperament constitu- nally cold, and principles essentially conservative, he d none of the generous sympathies inspired by an ardent ve of liberty; in the resistance of the Americans he saw thing but a rising against authority, to be put down by rce of arms; and, though possessing a mind accustom- to develope political results, and to estimate the remote nsequences of changes in the social relations of man- nd, he showed himself as insensible as the humblest Lord North's adherents to the real character of the uggle in which Britain was then engaged, and seems as tle to have anticipated the advantages which would ac- ue to mankind from the generous rivalry of two great tions sprung from a common stock, or to have foreseen at the separation of the colonies from the mother country is, sooner or later, inevitable, and that, even if then erted, it might take place during some political crisis egnant with still greater danger to the power of Britain. s sagacity, in short, was speculative, not practical; and want of political courage commensurate with a certain nd, undistinguishing dread of change, which forms the ost prominent characteristic of the sect of politicians to ich, from congeniality of sentiment, he had attached nself. For Lord North individually he seems to have erished the most sincere personal regard; and, though story will scarcely ratify Gibbon's estimate of his cha- cter, yet the fine tribute paid to the fallen minister in e preface to the fourth (quarto) volume of the Decline d Fall does honour to the historian's memory.

With regard to Gibbon's parliamentary silence, it is ghly probable that it proceeded from the cause which has himself explained. "After a fleeting illusive hope," ys he, "prudence condemned me to acquiesce in the mble station of a mute. I was not armed by nature d education with the intrepid energy of mind and voice,

> Vincentem strepitus, et natum rebus agendis.

midity was fortified by pride; and even the success of pen discouraged the trial of my voice." Another use besides physical inability, and the embarrassment a high literary reputation, seems also to have concurred repressing his ambition of oratorical fame. "Upon the ole," he writes to Mr Holroyd, "though I still believe hall try, I doubt whether nature, not that in some in- nces I am ungrateful, has given me the talents of an tor, and I feel that I came into parliament much too e to exert them." At the period to which this refers, bbon was eight and thirty; but at every brilliant epoch British oratory, the leading speakers have almost in- iably commenced their career long before the age of forty; and where there are exceptions to this rule, these will generally be found amongst those who have been bred to the kindred profession of the bar. Besides, in the confirmed habit of close, accurate, and laboured composition, there is something which disqualifies for free, prompt, and effective public speaking, in which readiness and fluency are far more indispensable requisites than precision and correctness.[1]

Having resolved to withdraw from public life, and fixed upon Lausanne as the place of his retreat, Gibbon entered into an arrangement with his old friend M. Deyverdun, who was now settled there; and having disposed of all his effects, excepting his library, he bade adieu to England in September 1783, and arrived at Lausanne nearly twenty years after his second departure. His reception was cordial, and the comparative advantages of his situation fully answered his expectations. His personal freedom, which had been somewhat impaired by the House of Commons and the board of trade, was now restored, and he was delivered from the chain of duty and dependence, as well as from the hopes and fears of political adventure. His English economy, which had been that of a solitary bachelor, who might afford occasional dinners, was exchanged for a more social mode of life, in which he enjoyed at every meal, at every hour, the pleasant conversation of the friend of his youth, whilst his table was daily provided for the reception of one or two extraordinary guests. In London he was lost in the crowd; at Lausanne he ranked with the first families, and his style of prudent expense enabled him to maintain a fair balance of reciprocal civilities. Instead of a small house between a street and a stable-yard, he now occupied a spacious and convenient mansion, with a garden of four acres laid out by the taste of M. Deyverdun, a rich scenery of meadows and vineyards descending to the Leman Lake, and the distant prospect beyond the lake crowned by the stupendous mountains of Savoy. In this catalogue of advantages, however, which we have abridged from the Memoirs, there is a perceptible intermixture of caprice and weakness; for surely a man of Gibbon's intellectual resources might easily have discovered situations in England adapted to every purpose of economy and retirement, yet calculated to afford at intervals the enjoyment of good society. But, not to mention that Gibbon in his habits was at least half a foreigner, it appears that, either from pride or modesty, he was averse to the society of his literary contemporaries, in which he does not seem to have been qualified to shine, and preferred, in his hours of relaxation, that style of company in which the conversation flows in an easy natural channel, and where the object is mutually to please, not to talk for effect. In society he sought to repose and recreate his mind, after the fatigue of research and the labour of composition, not to stimulate and excite it by what is called brilliant conversation; and, as enjoyment was his object, he naturally disliked and avoided company where the aim was rather display than social amusement.

Gibbon remained about a year at Lausanne before he resumed the composition of history; but having done so, he proceeded steadily with his laborious task, which he at length completed on the 27th of June 1787. The fourth volume was terminated by an abstract of the controversies respecting the Incarnation; in the fifth and sixth volumes the revolutions of the empire and the world are most rapid, various, and instructive, and the Greek and

---

"Extraordinary periods of public excitement," says a very able writer, "like the French Revolution, may suddenly, as it were, ture the powers of older men; but it may be remembered, that Mirabeau was by no means an unpractised speaker; and how ny of the leading orators of that period, displaying in the midst of flashy and histrionic declamation so much of vigorous and pow- ul eloquence, had been *avocats!*"—(*Quarterly Review*, vol. l. p. 286.)

Roman histories are checked by the hostile narratives of the barbarians of the East and West. The conclusion of his great, and, we may add, immortal work, the historian has commemorated in language strongly expressive of the emotions with which his mind was filled in contemplating the completion of that edifice which he had at length reared to perpetuate his fame. "I have presumed," says he, "to mark the moment of conception; I shall now commemorate the hour of my final deliverance. It was on the day, or rather the night, of the 27th of June 1787, between the hours of eleven and twelve, that I wrote the last page, in a summer-house in my garden. After laying down my pen, I took several turns in a *berceau*, or covered walk of acacias, which commands a prospect of the country, the lake, and the mountains. The air was temperate, the sky was serene, the silver orb of the moon was reflected from the waters, and all nature was silent. I will not dissemble the first emotions of joy on recovery of my freedom, and, perhaps, the establishment of my fame. But my pride was soon humbled, and a sober melancholy was spread over my mind, by the idea that I had taken an everlasting leave of an old and agreeable companion, and that whatsoever might be the future date of my history, the life of the historian must be short and precarious."[1]

With the manuscript of the three last volumes he set out from Lausanne, after a quiet residence of four years, and at the end of a fortnight arrived at the house of his friend Lord Sheffield, where he remained during his stay in England. The arrangements with the bookseller and printer were soon settled; but after the whole had passed through the press, the day of publication was delayed that it might coincide with the fifty-first anniversary of his birthday (8th May 1788), when the double festival was celebrated by a literary dinner at the house of the publisher, Mr Cadeli, where the historian "seemed to blush," whilst they read some complimentary stanzas written by Mr Hayley for the occasion. The sale of these volumes was rapid, and the work being generally read, was of course variously judged. The style was exposed to much academical criticism; a religious clamour was revived upon nearly the same grounds as before; and the reproach of indecency was loudly echoed by the more rigid censors of morals. This last charge he professes he could never understand, and assigns several reasons why it appeared to him unaccountable. First, an equal freedom in the former part, especially in the first volume, had passed without notice, or at least without censure: secondly, he considered himself as justified in painting the manners of the times, and regarded the vices of Theodora as forming an essential feature in the reign and character of Justinian: thirdly, he adds, that his English text is chaste, and that all the licentious passages in the notes are left in the obscurity of a learned language. But in offering such a vindication, or rather such an apology, the historian seems to have forgotten that it is no excuse of an offence against morals or decorum that, for a time, it may have escaped observation or censure; that sensuality may be censured without being lasciviously described; that it is not philosophically just to exhibit individual vices, in strong relief, as forming a general picture of the manners of a particular country; and that licentious passages are but thinly veiled by being "left in the obscurity" of languages which are taught at every school. In the opinion of a distinguished French critic, M. Villemain, Gibbon was dead to all lofty and generous emotions. This, however, is not doing justice to the historian. On most subjects, his mind was alive to the noblest sentiments, and calmly yet firmly arrayed on the side of humanity, justice, and the best interests of mankind; on two, the virtue of women and the magnanimity of Christians, he was incurably prejudiced. Porson, his bitterest and most malignant critic, admits that in his history, "his reflections are just and profound: he pleads eloquently for the rights of mankind and the duty of toleration; nor does his humanity ever slumber unless when women are ravished and Christians persecuted."

In the preface to his fourth volume, Gibbon, whilst he gloried in the name of Englishman, announced his approaching return to the banks of the Leman Lake; nor did his year's residence in England, on this occasion, induce him to alter his resolution, or even to entertain a wish of settling in his native country. A few weeks after the publication of his history, he accordingly set out for Switzerland, and, on the 30th of July 1788, arrived at Lausanne, where, after a full repast on Homer and Aristophanes, he involved himself in the philosophic maze of the writings of Plato. But the cheering prospect of happiness which had again wooed him to his favourite retreat was soon obscured by the illness and death of his friend Deyverdun; whilst the great political movement which had now begun to agitate France extended itself to Switzerland, and, throwing men's minds into a ferment of hope and fear, of anticipated improvement and foreboding apprehension, served to interrupt the tranquillity which had long reigned in that peaceful country. A swarm of emigrants of both sexes, attracted by similarity of manners and languages, as well as by the vicinity, flocked to Lausanne, and bringing with them a spirit of political discussion inflamed by passion and by prejudice, provoked hostility to their opinions, even whilst their misfortunes called forth sympathy. The language of disappointment on the one hand begot that of presumption on the other; domestic harmony was embittered by an infusion of party spirit; the ladies and gentlemen in Switzerland, as elsewhere, became suddenly transformed into politicians; and whilst the partisans of the old absolute monarchy denounced the advocates of constitutional freedom as rebels against their king and traitors to their country, the zealous missionaries of the new political faith scattered the seeds of discontent in those cities and villages, which, for more than two centuries and a half, no commotion had agitated. Of the manner in which the historian at this period employed his time we have little account. He appears to have amused himself by writing the Memoirs of his Life, which it was reserved for his friend Lord Sheffield to give to the world; and also to have projected a series of biographical portraits of eminent Englishmen from the time of Henry VIII., a design in the execution of which little or no progress seems to have been made. His habits of industry had by this time become impaired, and his studies, instead of being prosecuted as formerly with reference to a great object, were now so far restricted as merely to constitute the amusement of his morning hours.

He remained in Switzerland as long as he considered it prudent to do so, and only quitted that country when the execution of Louis XVI. and the declaration of war which almost immediately followed on the part of Great Britain, rendered it no longer a safe asylum for an Englishman who, it was well known, entertained strong anti-revolutionary pinions. Mr Gibbon left Lausanne in May 1793, arrived n June at Lord Sheffield's house in Downing Street, and oon afterwards settled, for the summer, with that noble- an at Sheffield Place. In October he went to Bath to ay a visit of kindness to his father's widow, and then proeeded to Althorp, the seat of Earl Spencer, from which he eturned to London. His health was visibly declining, and e now for the first time disclosed, by a letter to his friend ord Sheffield, the immediate cause, which he had hither- concealed from every human being, except a confiden- al servant. This complaint was originally a hernia, which ad at length produced hydrocele, and required imme- iate surgical treatment. Tapping afforded temporary elief; but as the original complaint was of about thirty ears standing, it had completely undermined his consti- ition, which could not for any length of time support e discharge; and he died, on the 16th of January 1794, reserving his senses and composure to the last. Absurd ports as to the manner of his death were circulated at e time, and implicitly believed by many credulous per- ons. But all these stories have been refuted by the au- oritative relation of his friend and biographer, who has ated the real circumstances attending his demise with qual clearness and simplicity. Mr Gibbon did not at y time show the least sign of alarm or apprehension of eath; and, in fact, it does not appear that he ever thought imself in danger, or conceived his departure from this rthly scene to be so near at hand.

---

[1] "I will add two facts," says he, "which have seldom occurred in the composition of six, or at least five quartos. 1. My first rough manuscript, without any intermediate copy, has been sent to the press. 2. Not a sheet has been seen by any human eyes, excepting those of the author and printer; the faults and the merits are exclusively my own." This must be taken with a slight deduction, inasmuch as it appears from a previous part of his Memoirs, that he three times composed the first chapter of the first volume, and twice the second and third, before he was satisfied with them; and also, that although "he was soon disgusted with the modest practice of reading the manuscript to his friends," this had nevertheless been, to a certain extent, done by him.

The personal character of Mr Gibbon, which was upon e whole highly estimable, may be correctly appreciated om the Memoirs which he left behind him. In these his ntiments are disclosed without the reserve which he em- oyed in his more laboured compositions, and his mental ilings are detailed with an ingenuous candour which com- ands our respect and confidence. He frankly confesses e vanity of the author and the pride of the gentleman; e vanity of one of the most successful authors of modern mes, and the pride of a gentleman of amiable manners d high accomplishments. It must, however, be admit- d that his anxiety for fame sometimes obscured the lus- e of his social qualities, separated him too widely from s literary contemporaries, and occasionally led him to eak of his opponents with a contemptuous arrogance at riance with the general tone of his bland and moderate aracter. His conversation, though not enlivened by wit, r adorned with those lighter graces in which the French greatly excel all other nations, is yet said to have been ch in various information, communicated in a calm and greeable, though somewhat peculiar manner; but in mpany he seldom brought forward his vast treasures of owledge, and was more ambitious to be thought a man the world than a mere scholar or author. "As to his anners in society," says M. Suard, who knew him well, without doubt the agreeableness (*amabilité*) of Gibbon as neither that yielding and retiring complaisance, nor at modesty which is forgetful of self; but his vanity *mour-propre*) never showed itself in an offensive manner. nxious to succeed and to please, he wished to command tention, and obtained it without difficulty by a conver- tion animated, sprightly, and full of matter. All that as dictatorial (*tranchant*) in his tone betrayed not so uch that desire of domineering over others, which is ways offensive, as confidence in himself; and that con- lence was justified both by his powers and by his suc- ss. Notwithstanding this, his conversation never car- ed one away (*n'entraînait jamais*); its fault was a kind arrangement which never permitted him to say any ing unless well." In this elaborate and artificial struc- re of his conversation, we are irresistibly reminded of e characteristic qualities and defects of his style, in hich, according to Porson, the thread of his verbosity is sometimes finer than the staple of his argument, and where, in endeavouring to avoid vulgar terms, he occasionally dignifies trifles, and clothes common thoughts in a dress which would be rich enough for the noblest ideas.

But although Gibbon has disclosed much of his character in his Memoirs, there are some points left unexplained, concerning which it would be very desirable to be better informed. He has told us much of the progress of opinions in his mind; of his conversion to popery, which, considering at what age it occurred, he has treated with disproportionate gravity; and of his reconversion to protestantism, which he has related with more brevity and obscurity. But at the latter of these points he stops short; we leave him a good Protestant in the hands of M. Pavilliard, and, after a considerable interval, we find him transformed into an implacable enemy of Christianity, without the pretence of a quarrel, or any previous declaration of hostilities. By what process was this singular transition effected? by what train of reading or interchange of sentiments did he contract this causeless inveteracy? Porson has charged him with often making, where he cannot find, an occasion to insult our religion, "which," says that incomparable Hellenist, "he hates so cordially that he might seem to revenge some personal injury." The accusation is no doubt a little too sweeping; yet whence arose the undeniable antipathy on which it is grounded? On this subject we are left entirely to conjecture; but, without venturing to affirm any thing, it may not unreasonably be attributed to his intimacy with the French writers, particularly Helvetius, and to his correspondence with Hume, to whom he looked up with the reverence of a disciple; connections which probably led him to think that the farther he departed from the Christian faith, the nearer he approached to the perfection of the philosophical character.

As an historian, the universal acknowledgment of the literary world has placed him in the highest rank; and if his taste had equalled his knowledge, if in his narrative the grace of simplicity had concealed the artifice of elaboration, he would, even in that rank, have stood without a rival. But in all the diversified charms of interesting and pathetic relation he is as much inferior to Robertson, as he excels that writer in extent and variety of knowledge, in deep and penetrating sagacity, in comprehensive concentration, and, above all, in the unrivalled mastery which he exercised over his vast stores of learning;—and if, in these respects, he is likewise superior to Hume, which can scarcely be disputed, he at the same time falls far short of what he has himself characterised as the careless inimitable beauties of that elegant and philosophical historian. Yet, with every deduction that can reasonably be made, enough will remain to support the high reputation of his great work, and to entitle its author to the respect and admiration of every succeeding age. If his laborious system of compilation, the depth and accuracy of his research, partook of the patient plodding erudition of the north, both the merits and defects of his manner of composition were essentially French; and it is not difficult to discern the influence of Voltaire and his school on the philosophical views no less than the sarcastic periods of the historian. Yet it is not in France alone, but likewise among the profound inquiring scholars of Germany, that Gibbon maintains his ground. His chapter containing a condensed abstract of the Roman law was translated by Hugo, in order that it might serve as a text-book for his own prelections on that system of jurisprudence; and the recent editors of the later historians of Rome, particularly of Ammianus Marcellinus, and of the Byzantine Collection, defer to his interpretations, sometimes of the text, always of the meaning of their authors; whilst, even where their own researches have thrown further light on the periods comprehended in his work, their language is uniformly that of acknowledgment of his general accuracy, and of respect for his elevated genius. In a word, Gibbon anticipated that happy union, which we can scarcely hope to see more perfectly consummated, of the indefatigable erudition of the Germans, with the lucid arrangement of the French, and their lively manner of developing their views and relating facts; condensing and perfecting the whole with the masculine boldness and solidity of English judgment. In Gibbon indeed there were wanting a more free and natural style, a purer moral taste, and a philosophy superior to the narrow prejudices of a sect; but, with these exceptions, there is every thing to be admired in him as an historian. An erudition vast, solid, and varied; a criticism equally exact and ingenious; an interest of narration, if not always equal, at least sufficiently sustained to prevent languor; views sometimes profound, often comprehensive, almost always just; reflections original, striking, and piquant; and the art of connecting the facts of the history with enlarged ideas, of which the writer himself did not perhaps perceive all the consequences, but which excite reflection in the mind of the reader; such are the obvious merits of Gibbon as an historian, such the qualities which ensure the permanence of his fame. His defects, though much less apparent, and in some measure concealed from common observation by the extreme artifice of his composition, may nevertheless be brought out with equal distinctness. The first and the greatest of these is that want of elevation of sentiment, which is the more apt to impose on our reason, that the historian never thinks himself so reasonable as when he regards virtue and vice with equal indifference. The imagination of Gibbon was active, and his temperament cold; he was easily induced to admire that which astonished; he invariably misjudged sentiments and emotions which he had never experienced. After labouring to depreciate the heroic courage of the Christian martyrs, he takes pleasure in celebrating the ferocious exploits of Timur and his Tartars; material grandeur, so to speak, strikes him more forcibly than moral greatness; the transports of sublime virtue affect not his soul, whilst the outbreakings of barbarous force seduce his imagination and mislead his judgment. Having no fixed principles in morals, politics, and public economy, or in regard to the constitution of society and the history of civilization, he betrays an uncertainty in his opinions which is sometimes embarrassing; his work does not tend towards one great end; its march is not steady and uniform; in a word, it is the production of an enlightened man, endowed with that philosophical spirit which examines, decomposes, and describes with ability all the details of the events of history, rather than the work of a great philosopher, who, from an immense accumulation of facts, deduces those high conceptions and those truths of a superior order which apply to all histories and to all ages.[1]

Gibbon spoke and wrote French with correctness and elegance; but the style of his English compositions, particularly of his history, has been alternately admired and censured. Porson, who was by no means inclined to spare him, has the candour to admit that his style is emphatic and expressive, and that his sentences are harmonious. But this seems to us inadequate eulogy. For, however overloaded, and at times measured almost to monotony, the style of Gibbon deserves the higher praise of animation, which keeps the attention continually awake,—of descriptive richness, which brings both manners and local scenery in living freshness before the imagination,—and of energy, which deeply impresses his more sententious truths upon the memory. "Gibbon may be overlaboured, but he is rarely diffuse, and never dull; he may overstrain the attention, but he never permits us to sleep; he may want simplicity, but he never wants force." Conciseness, vivacity, and often brilliancy, are his most striking characteristics; and if he has neither the careless, easy transparency of Hume, nor the sustained majesty of Robertson, he is more animated than the one, and more picturesque than the other.[2]

In the year 1796, Lord Sheffield published, in two volumes quarto, Gibbon's *Miscellaneous Works*, including those Memoirs of his own Life and Writings to which we have so often referred. This publication likewise contains a large collection of letters, either written by or addressed to the historian; abstracts of the books he had read, with reflections thereon; extracts from a journal of his studies; a collection of remarks and detached pieces on various subjects; outlines of his History of the World; his *Essai sur l'Etude de la Littérature*, republished; Critical Observations on the design of the sixth book of the Æneid; a Dissertation on the subject of *L'Homme au Masque de Fer; Mémoire Justificatif pour servir de Réponse à l'Exposé de la Cour de France;* his Vindication of his History; Antiquities of the House of Brunswick; and an address to the public on the subject of a complete edition of our ancient historians. But of all these miscellanies, his journal, abstracts, and remarks are the most curious and instructive in a literary point of view. They ontain much valuable criticism; exhibit a plan of indus- y such as few men ever pursued with equal constancy; how an amount of labour approaching to what we read f the indefatigable scholars of the sixteenth and seven- eenth centuries; and serve to teach scholars of all ages hat no station of permanent eminence can ever be reached ithout persevering exertion, and that, apart from intel- ectual application, knowledge becomes useless. wit ridi- ulous, and genius itself contemptible.

---

[1] The French Revolution showed, in a strong light, Mr Gibbon's want of fixed opinions; and the just horror which it inspired had the effect of leading him into a new exaggeration. He then maintained that he had only attacked Christianity because the Christians destroyed Polytheism, which was the ancient religion of the empire. "The primitive church of which I have spoken a little familiarly," said he, in a letter to Lord Sheffield, "was an innovation; and I was attached to the ancient establishment of paganism." If this was not an after-thought, it would afford a key to much that has been considered doubtful, or difficult of explanation, in the history of the historian's opinions. In his Memoirs we meet with the following passage: "I beg leave to subscribe my assent to Mr Burke's creed on the Revolution of France. I admire his eloquence, I approve his politics, I adore his chivalry, and I can almost excuse his reverence for church establishments. I have sometimes thought of writing a dialogue of the dead, in which Lucian, Erasmus, and Voltaire should mutually acknowledge *the danger of exposing an old superstition to the contempt of the blind and fanatic multitude.*

[2] The following beautiful and discriminating observations on the taste and style of Gibbon are extracted from a review of his posthumous works, by Sir James Mackintosh, which originally appeared in the *Monthly Review:* "The reader will not learn without wonder that Swift and Addison were among the earliest models on which our celebrated historian laboured to form his taste and his style. If the composition of these writers continued to be the object of his imitation, the history of literature does not exhibit so striking an example of a man of such great talents so completely disappointed in his purpose. It may be observed that, even in the very act of characterising Swift and Addison, he has deviated not a little from that beautiful simplicity which is the peculiar distinction of these pure and classical writers. Nor can we think that Mr Gibbon, however he may have in some measure emulated the historical merit, has exactly trodden in the literary footsteps of Dr Robertson. Inferior, probably, to Mr Gibbon, in the vigour of his powers; unequal to him, perhaps, in comprehension of intellect, and variety of knowledge; the Scottish historian has far surpassed him in simplicity and perspicuity of narration; in picturesque and pathetic description; in the sober use of figurative language; and in the delicate perception of that scarcely discernible boundary which separates ornament from exuberance, and elegance from affectation. He adorns more chastely in addressing the imagination; he narrates more clearly for the understanding; and he describes more affectingly for the heart. The *defects* of Dr Robertson arise from a less vigorous intellect; the *faults* of Mr Gibbon from a less pure taste. If Mr Gibbon be the greater man, Dr Robertson is the better writer." (See *Notice of the Life, Writings, and Speeches of Sir James Mackintosh*, prefixed to the fragment entitled *History of the Revolution in England* in 1688, London, 1834.)

(Gibbon's *Miscellaneous Works*, vol. i.; *Memoirs*, &c.; *listoire de la Décadence et de la Chute de l'Empire Ro- ain, traduite de l'Anglais d'Edouard Gibbon*, by M. uizot, preceded by a Notice of the Life and Character f Gibbon by M. Suard, and accompanied with critical nd historical notes, for the most part relating to the his- ory of the propagation of Christianity, Paris, 1828; Cha- eaubriand, *Etudes ou Discours sur la Chute de l'Empire Romain*, Paris, 1830; *Quarterly Review*, vol. l. p. 273 t seqq. Chalmers, art. Gibbon; *Biographie Universelle*, rt. Gibbon.) (A.)

GIBBOUS, a term in *Medicine*, denoting any protube- ance or convexity of the body, such as hunched or hump- acked.

GIBBOUS, in *Astronomy*, a term used in reference to the nlightened parts of the moon, while she is moving from the rst quarter to the full, and from the full to the last quar- er; for all that time the dark part appears horned or fal- ated, and the illuminated part hunched out, convex, or ibbous.

GIBELINES, or GHIBELINES, a famous faction in Italy, pposed to another called the GUELPHS. Those two fac- ons ravaged and laid waste Italy for a long series of years; o that the history of that country, for the space of two cen- uries, is little more than a detail of their mutual violence and laughter. The Gibelines stood for the emperor against he pope; but concerning their origin and the reason of heir names we have only a very obscure account. Ac- ording to the generality of authors, they rose about the ear 1240, upon the Emperor Frederick II. being excom- nunicated by Pope Gregory IX. Other writers maintain, hat the two factions arose ten years before, though still nder the same pope and emperor. But the most probable pinion is that of Maimbourg, who says that these factions arose in consequence of a quarrel between two ancient and llustrious houses on the confines of Germany; that of the Henries of Gibeling, and that of the Guelphs of Adorf.

GIBEON, a city seated on an eminence about forty fur- ongs northward from Jerusalem. The Gibeonites were lescended from the Hivites, the old inhabitants of that country, and possessed four cities, of which Gibeon was the apital.

GIBLETS, the offals or entrails of a goose, including he heart, liver, feet, gizzard, &c. The word is supposed o be formed from the French *gobeau*, a mouthful. Gib- ets form a considerable article in cookery.

GIBRALTAR, a famous promontory, or rather penin- ula, of Spain, situated in north latitude 36. 6., and west lon- gitude 5. 17. To the ancients it was known by the name of *Calpe*, and was also called one of the *Pillars of Hercules*; by the Arabians it is called *Gebel Tarek*, that is, the Mount of Tarek, from the name of the Saracen general who conquered Spain in the beginning of the eighth century. The whole is one immense rock. "Its form," says Major Imrie, "is oblong; its summit a sharp craggy ridge; its direction is nearly from north to south; and its greatest length, in that direction, falls very little short of three miles. Its breadth varies with the indentations of the shore, but it nowhere exceeds three quarters of a mile. The line of its ridge is undulated, and the two extremes are somewhat higher than its centre. The summit of the Sugar Loaf, which is the point of its greatest elevation towards the south, is 1439 feet; the Rock Mortar, which is the highest point to the north, is 1350; and the Signal House, which is nearly the central point between these two, is 1276 feet above the level of the sea. The western side of the mountain is a series of rugged slopes, interspersed with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the north-west, where what are called the Lines intervene, and a narrow passage of flat ground that leads to the isthmus, and is entirely covered with fortification. The eastern side of the mountain mostly consists of a range of precipices; but a bank of sand, rising from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its southern extremity falls, in a rapid slope, from the summit of the Sugar Loaf, into a rocky flat of considerable extent, called Windmill Hill.

"The principal mass of the mountain rock consists of a gray dense (or what is generally called primary) marble; the different beds of which are to be examined in a face of 1350 feet of perpendicular height, which it presents to Spain in a conical form. These beds, or strata, are of various thickness, from twenty to upwards of forty feet, dipping in a direction from east to west, nearly at an angle of thirty-five degrees. In some parts of the solid mass of this rock are found testaceous bodies entirely transmuted into the constituent matter of the rock, and their interior hollows filled up with calcareous spar; but these do not often occur in its composition, and its beds are not separated by any intermediate strata." (*Transactions of the Royal Society of Edinburgh*, vol. iv.)

The town lies along the bay upon the west side of the mountain, on a declivity; by which, generally speaking, the rains pass through it, and keep it clean. The old town was considerably larger than the new. Many of the streets are narrow and irregular, and the buildings are of different materials; some of natural stone, extracted from the quarries, others of a factitious or artificial stone, and a few of brick. The people are supplied with fresh provisions, chiefly from the coast of Barbary, as well as fruit, roots, and vegetables of all sorts. Besides what is properly called the town, there are several spacious and commodious public edifices erected, such as barracks for the soldiers, with apartments for their officers, magazines of different kinds, storehouses for provisions, &c. The population of the town, exclusive of the garrison, is above 12,000, being partly British, and partly Spaniards, Italians, Jews, and even Moors, who are all attracted by mercantile enterprise. This town may be said to have two ports; the first lying to the north, which is proper only for small vessels; the other very commodious for large vessels, which has a fine stone quay. The bay is very beautiful and capacious, being in breadth about five miles, and in length eight or nine, with several small rivers running into it. It is very advantageous to the place. There is no ground to be found in the middle of it at one hundred fathoms depth, so that a squadron may lie there in great safety; the breezes from it are very refreshing; and it contributes likewise to the subsistence of the inhabitants by supplying them with abundance of fish.

This important fortress seems to have been first particularly noticed as a place of consequence in the year 712. At that time the general of the Caliph Alwalid landed with an army of 12,000 men on the isthmus between Mount Calpe and the continent; and, that he might secure an intercourse with Africa, he ordered a castle to be built upon the face of the hill. Part of this building still remains; and, from an inscription discovered above the principal gate, it appears to have been finished in 725. It continued in the possession of the Saracens till the beginning of the fourteenth century, when it was recovered by Ferdinand king of Castille. In 1333, however, it was obliged to surrender to the son of the Emperor of Fez, who came to the

Gibson.

assistance of the Moorish king of Granada. An attempt was made upon it in 1349, by Alonzo king of Castille; but when the fortress had been reduced to the last extremity, a pestilential fever broke out in the Spanish camp, which carried off the king himself, with great part of his army; after which the enterprise was abandoned.

The fortress continued in the possession of the Saracen descendants of the prince of Fez until the year 1410, when it was taken possession of by Joseph III. king of Granada. A design of attacking it was formed by Henry de Guzman in 1435; but the enterprise having miscarried through his imprudence, he was defeated and slain. However, it was at length taken after a gallant defence, by his son John de Guzman, in 1462; and since that time it has remained in the hands of the Christians. In 1540 it was surprised and pillaged by Piali Hamet, one of Barbarossa's corsairs; but the pirates having fallen in with some Sicilian galleys, were by them defeated, and all either killed or taken.

In the reign of Charles V. the fortifications of Gibraltar were modernized and greatly strengthened. It yielded, however, to a British force sent against it under Sir George Rooke in 1704, and has ever since remained subject to Britain. Since the English became masters of it, its fortifications have been so much improved as to render it impregnable. The memorable siege commenced by the Spaniards in the course of the American war was signalized by the glorious defence of General Elliot, and by the total destruction, in 1782, of an apparatus of floating batteries, mounting above 200 pieces of cannon, from which both France and Spain had anticipated the most splendid success.

The possession of Gibraltar is esteemed of great consequence to Britain. It not only gives us the command of the Straits, and their navigation, but affords refreshment and accommodation to our fleets in time of war, and to our merchantmen at all times; which, to a maritime power, is a great advantage. It is otherwise highly favourable to our trade in the Mediterranean and Levant. It saves us the expense of squadrons or convoys, upon any disputes or disturbances that may happen among the neighbouring powers, and which would otherwise be necessary for the protection of our navigation.

GIBSON, Richard, an English painter, commonly called the *Dwarf*, was originally page to a lady at Mortlake, who, observing that his genius led him to painting, had the generosity to get him instructed in the rudiments of that art. Having devoted himself to Sir Peter Lely's manner, he copied his pictures to admiration, especially his portraits; and his paintings in water colours were also esteemed. He was in great favour with Charles I. who made him page of the back stairs; and he had the honour to instruct in drawing Queen Mary and Queen Anne when they were princesses. He married one Mrs Anne Shepherd, who was also a dwarf, on which occasion King Charles I. honoured their marriage with his presence, and gave away the bride. Mr Waller wrote a poem on this occasion, entitled The Marriage of the Dwarfs; in which are these lines:

> Design or chance makes others wive.
> But nature did this match contrive;
> Eve might as well have Adam fled,
> As she deny'd her little bed
> To him for whom heav'n seem'd to frame
> And measure out this only dame.

Mr Fenton, in his notes on this poem, observes that he had seen this couple painted by Sir Peter Lely; and that they were of an equal stature, each being three feet ten inches high. They had nine children, five of whom arrived at maturity, and were well proportioned, being of the usual standard of mankind. But what nature denied this couple in stature, she gave them in length of days; for Mr Gibson died in the seventy-fifth year of his age, and his wife having survived him almost twenty years, died in 1709, aged eighty-nine.

Gibson, *Dr Edmund*, bishop of London, was born in Westmoreland in 1699. He applied himself early and vigorously to learning, and displayed his knowledge in several writings and translations, which recommended him to the patronage of Archbishop Tennyson. He was appointed domestic chaplain to his grace; and soon afterwards became rector of Lambeth, and archdeacon of Surrey. Becoming thus a member of the convocation, he engaged in a controversy, which was carried on with great warmth by the members of both houses, and defended his patron's rights, as president, in eleven pamphlets; he then formed and completed his more comprehensive scheme of the legal duties and rights of the English clergy, which was at length published under the title of *Codex Juris Ecclesiastici Anglicani*, in folio. Archbishop Tennyson having died in 1715, and Dr Wake bishop of Lincoln having become archbishop of Canterbury, Dr Gibson succeeded the latter in the see of Lincoln, and in 1720 was promoted to the bishopric of London. He now not only governed his diocese with the most exact regularity, but by his great care promoted the spiritual affairs of the church of England colonies in the West Indies. He was extremely jealous of the privileges belonging to the church; and therefore, though he approved of the toleration of the Protestant Dissenters, he continually guarded against all the attempts made to procure a repeal of the corporation and test acts; but his opposition to those licentious assemblies called *masquerades* gave great umbrage at court, and effectually excluded him from all further favours. He spent the latter part of his life in writing and printing pastoral letters, visitation-charges, occasional sermons, and tracts against the prevailing immoralities of the age. His pastoral letters are justly esteemed as the most masterly productions against infidelity and enthusiasm. His most celebrated work, the *Codex*, has been already mentioned. His other publications are, 1. An edition of Drummond's *Polemo-Middinia*, and James V. of Scotland's *Cantilena Rustica*, with notes; 2. the *Chronicon Saxonicum*, with a Latin translation, and notes; 3. *Reliquiæ Spelmannianæ*, the posthumous works of Sir Henry Spelman, relating to the laws and antiquities of England; 4. An edition of Quintilian *De Arte Oratoria*, with notes; 5. An English translation of Camden's *Britannia*, with additions, two volumes folio; and, 6. A number of small pieces, which have been collected together and printed in three volumes folio. His intense application to study impaired his health; notwithstanding which, he attained the age of seventy-nine. He expired in September 1748, after an episcopate of nearly thirty-three years.

GIDEON, the son of Joash, of the tribe of Manasseh. He dwelt in the city of Ophrah; and had a very extraordinary call to deliver the Israelites from the oppression of the Midianites, to which they had become subject after the death of Barak and Deborah. Having effected their deliverance by supernatural aid, he was chosen judge of Israel in the year of the world 2759, and died in 2768.

GIESSEN, a city of the grand duchy of Hesse, in Germany, in the province of Upper Hesse. It stands on the river Lahn, at its junction with the Wieseck, and is the seat of the several boards of government, of justice, and of the ecclesiastical superintendent. The university, founded in 1607, is flourishing, and has twenty-three professors and between two and three hundred students. It has connected with it two public libraries, a botanical garden, and various museums. It contains 720 houses and 7000 inhabitants, including the university. Long. 9. 38. E. Lat. 50. 36. N. It is the capital of a bailiwick of the same name, comprehending two cities, one market-town, and thirty-five villages, with 3219 houses and 20,450 inhabitants.

Gifford.

GIFFORD, William, a distinguished critic, satirist, id dramatic annotator, was born at Ashburton, in Devonire, in April 1757. Although his immediate ancestors ssessed considerable property in their native county, and ere there accounted gentlemen, yet a series of indiscreons had deprived them of the greater part of their subance; and when the subject of this memoir was born, his ither only possessed two small estates. The elder Gifford, hose roving propensities had driven him to sea, and also d him "to wander in some vagabond society," as his son forms us, established himself after his marriage, as a umber and glazier, at South Molton. But his habits were isettled and desultory; he went again to sea, and once ore returned without having acquired any wisdom from s misfortunes; and he died at last, "of a decayed and ined constitution, before he was forty." When this event ppened, his son William had not completed his thirteenth ear. He had been sent to school to read, write, and ciher; but, according to his own account of himself, he ere made "a most wretched progress." In less than velve months after the death of his father, his mother folwed her husband to the grave, and after various vicissides young Gifford was sent on board of a coasting vesl, by the person under whose guardianship he had been aced. This individual, who was his godfather, and into hose hands the effects of Gifford's parents had fallen, relled him from his nautical pursuits, principally, it would ppear, on account of the outcry which the people of Asharton raised against him for the manner in which he had eated his young charge. Gifford was now sent to school, here he made great progress, especially in arithmetic; but om this he was in a short time withdrawn, and apprenticed a shoemaker. He was now in his fifteenth year, and he as articled to serve until he was twenty-one. But he oroughly hated his new profession, and whenever leisure forded him opportunities, he prosecuted his favourite udy of mathematics. Few facilities for study fell to his t, but his ingenuity supplied the deficiency; and the eans which he adopted of improving himself, as well as e irrepressible perseverance which he displayed, affords striking instance of the force of genius in compensating d overcoming the disadvantages of untoward circumances. He also began to write verses, though not at this eriod for amusement, but only when he wanted money r his mathematical pursuits. But his devotedness to his udies seems to have rendered him indifferent to the conerns of his master, whose indignation was accordingly oused. He requested young Gifford to give up his books d papers; and this being refused, he proceeded to the arret of the delinquent, which he thoroughly sacked. Beg now deprived of his sole means of improvement, almost f enjoyment, Gifford began to display a degree of sulleness, reserve, and discontent, which made him an object of islike to his fellow-workmen. However, in this humble d obscure condition, poor beyond the common lot, he ttracted the notice of Mr Cookesley, a surgeon of the own in which he resided. This excellent individual deep- interested himself in behalf of Gifford, and set on foot a ubscription to purchase his freedom from the latter part of is indentures, and to pay for his education; a scheme hich completely succeeded. Thus, by an act of generoty, which it is pleasing to record, was the humble shoeaker rescued from his abject state, and placed in circumances which enabled him to gain the highest literary hoours, and to sit in judgment upon the most gifted men of is time.

After having passed two years at school, he was pronouned fit for the university; and by the active benevolence of Ir Cookesley he was enabled to proceed to Oxford, where e obtained the situation of Bible reader in Exeter College. Whilst at this place, he undertook a translation of Juvenal, poetry having now become his delight. A subscription for publishing it was set on foot; but during the progress of this undertaking his benefactor died; a circumstance which ultimately, and perhaps fortunately, prevented him from publishing a translation of the great Roman satirist, at least for a time. By an accidental occurrence, however, he became known to Lord Grosvenor, who invited him to his house. He accordingly quitted Oxford, and took up his residence with that nobleman, under whose hospitable roof he prosecuted the translation of Juvenal, until called upon to accompany the son of his patron to the Continent. With this young nobleman he spent, in two successive tours, many years, "of which," he says in his autobiography, "the remembrance will always be dear." Although Mr Gifford was principally engaged upon his translation of Juvenal, its publication was preceded by several other productions, by which at the time he obtained great popularity. The first was the *Bavaid*, a paraphrase on the first satire of Persius. This production appeared in 1794, and was levelled at a class of poetasters who deluged the daily prints of the time with their weak and effeminate lucubrations, which were likewise deformed by the most fulsome adulation of each other. The satire had the effect of completely extinguishing this tuneless tribe. Mr Gifford's next production, which appeared the following year, was entitled the *Mæviad*; an imitation of Horace, and directed against the corruptions of the drama. This work was only partially successful, for the malady which it was intended to cure had its seat in public manners rather than in the affectation of individuals. In both of these works Mr Gifford displays the most caustic severity and personality; and it has been questioned whether the harmless generation of ephemeral songsters and dramatists deserved the abuse with which they were assailed. In 1800 he published his *Epistle to Peter Pindar*, an attack which brought him little else but disquietude; the laughter of the one satirist being quite as formidable as the gall of the other. About this period Mr Gifford became connected with a set of men of wit and genius, at the head of whom was Mr Canning, who resolved upon establishing a weekly paper for the purpose of exposing to ridicule the political agitators of the time. This print was called the *Anti-Jacobin*, and Mr Gifford became its editor. The ministerial connection thus formed was of some use to him, as by it he obtained the paymastership of the band of gentlemen pensioners; and at a subsequent period he was made a double commissioner of the lottery. In 1802 appeared his English version of Juvenal, a work which may be said to have engrossed the greater part of his life. It was ushered into the world with every possible advantage, headed by a dedication to Earl Grosvenor, and with the translator's autobiography prefixed to it. The translation is able and spirited, although it is occasionally diffuse and unharmonious, and not unfrequently coarse in its diction. In 1805 Mr Gifford published an edition of the Plays of Massinger in four volumes; and in 1816 the Works of Ben Johnson, in nine volumes. In his annotations upon both these dramatic poets he displays great acuteness and industry; but in exposing the blunders of previous commentators, he shows not a little of his characteristic acerbity. In 1821 he published a version of Persius; and since his death his editions of the dramatic works of Ford and Shirley have been given to the world, accompanied with able and acute notes.

It was, however, as editor of the *Quarterly Review* that Mr Gifford became most generally known. The success of the *Edinburgh Review*, in advocating liberal principles in politics, suggested to the opposite party the idea of a counterpoise in the shape of the journal above named, which was accordingly carried into effect in 1809, and Mr Gifford entrusted with its management. The scheme completely succeeded; and it is allowed by all parties, that as editor of this distinguished journal, Mr Gifford displayed uncommon skill and ability. No man possessed a finer tact in discerning the weak and bad points of an author, when his object was to turn him into ridicule; none could hold them up to laughter with more felicitous acrimony. From the time of his taking the charge of the *Quarterly Review* until his death, few circumstances of any moment occurred in the life of Mr Gifford, except the publication of the works already mentioned. He continued the editorship until about two years before his death, which took place on the 31st of December 1826.

From the prominent position which Mr Gifford occupied in the literary world, his character has been the subject of severe animadversion by one party, and of exaggerated eulogy by another. Of his great talents there can be no doubt. His sagacity and quickness of apprehension were striking, and the rapidity with which he acquired knowledge is proved by his having prepared himself for the university after being only two years at school. His wit was distinguished for caustic severity rather than for brilliancy, and he dealt more in invective than in polished repartee. As a poet he cannot be said to rank very high; but that he had a keen perception of the beauties of the noblest inspirations of the muse, and could point them out with great felicity, provided political feelings did not intervene to pervert his judgment, is proved by his many admirable criticisms, and by the confidence which Lord Byron and others reposed in his opinions. In private life Mr Gifford was modest and unassuming; and amongst the numerous parties, poetical, political, or religious, who occasionally suffered by his castigations, none of them ever ventured to recriminate by attacking the moral character of the editor of the *Quarterly Review*. The memoir of himself, which he prefixed to his version of Juvenal, is one of the most remarkable pieces of autobiography extant. It is written with ability and manly feeling, as well as with unaffected modesty and apparent candour. (R. R. R.)

GIFT, in the law of England, is a conveyance which passes either lands or goods, and is of a larger extent than a grant, being applied to things moveable and immoveable; yet as to things immoveable, when taken strictly, it is applicable only to lands and tenements given in tail. But *gift* and *grant* are too often confounded.

New Year's GIFTS, presents made on new year's day, as a token of the giver's good will, as well as by way of presage of a happy year. This practice is very ancient, the origin of it among the Romans being referred to Tatius king of the Sabines, who reigned at Rome conjointly with Romulus, and who, having considered as a good omen a present of some sprigs of vervain gathered in a wood consecrated to Strenia, the goddess of strength, which he received on the first day of the new year, authorized this custom afterwards, and gave to these presents the name of *Strenæ*. But however this may be, the Romans on that day celebrated a festival in honour of Janus; paid their respects at the same time to Juno; and avoided passing it in idleness, lest they should become indolent during the rest of the year. They sent presents to one another of figs, dates, honey, and other articles, to show their friends that they wished them a happy and agreeable life. Clients, that is to say, those who were under the protection of the great, carried presents of this kind to their patrons, adding to them a small piece of silver. Under Augustus, the senate, the knights, and the people, presented such gifts to the emperor, and in his absence deposited them in the Capitol. Of the succeeding princes, some adopted this custom, and others abolished it; but it always continued amongst the people. The early Christians condemned it, because it appeared to be a relic of paganism, and a species of superstition; but when it began to have no other object than that of being a mark of veneration and esteem, the church ceased to disapprove of it.

GIGG, GIGA, or JIG, in *Music* and *Dancing*, a gay, brisk, sprightly composition, yet in full measure, as well as the allemand, which is more serious. Ménage conceives the word to spring from the Italian *gieg*, a musical instrument mentioned by Dante. Others suppose it to be derived from the Teutonic *giga*, or *ghiighe*, a fiddle. This is a favourite air in most nations of Europe; its characteristic is duple time, and it consists of two strains, without any determinate number of bars.

GIGLEWICK, a township of the west riding of the county of York, in the wapentake of Staincliff and Ewercross. It stands at the base of a rock 300 feet in height, on the summit of which is the parish church, to which the ascent is by steps cut in the limestone. Within the parish are some valuable stone quarries. The population amounted in 1801 to 2201, in 1811 to 2428, in 1821 to 2817, and in 1831 to 3017.

GIJON, a city of Spain, in the province of Asturias. It is built at the foot of a hill, on the sea shore, and has a port, which is by far the best in the province, and in which the greater portion of its foreign commerce centres. The harbour is well defended by a castle on the hill near the city, and by batteries constructed on the mole. The entrance is very narrow and difficult, and the difficulty gradually increases, from the sea receding in such a manner as to alarm the merchants with the apprehension that their harbour will in a few years become wholly dry land. The city is very beautiful, the streets are wide and straight, and cross each other at right angles; and most of the houses are of recent construction, and well built. An institution for the promotion of scientific knowledge was formed here in 1794, and the pupils are instructed in mathematics, and the application of geometry to mechanics, navigation, and the other arts; and mineralogical and geological lectures are delivered. Its longitude is 5. 13. 39. west from London, and its latitude 43. 35. 10. north. This town contains 3200 inhabitants, who are employed in making earthenware, buttons, and cider.

GILBERT, or GILBERD, *William*, a physician, born at Colchester in the year 1540, was the eldest son of the recorder of that borough. Having spent some time in both universities, he went abroad; and on his return settled in London, where he practised with considerable reputation. He became a member of the College of Physicians, and physician in ordinary to Queen Elizabeth, who, we are told, gave him a pension to encourage him in his studies. From his epitaph it appears that he was also physician to King James I. He died in the year 1603, aged sixty-three, and was buried in Trinity Church, Colchester, where a handsome monument was erected to his memory. His books, globes, instruments, and fossils, he bequeathed to the College of Physicians, and his picture to the school gallery at Oxford. He wrote, 1. De Magnete, magneticisque Corporibus, et de magno magnete Tellure, Physiologia nova, London, 1600, folio; 2. De Mundo nostro sublunari Philosophia nova, Amsterdam, 1651, 4to. He was also the inventor of two mathematical instruments for finding the latitude at sea without the help of sun, moon, or stars. A description of these instruments was afterwards published by Thomas Blondeville, in his *Theoriques of the Planets*.

GILBERT, *Sir Humphrey*, a brave officer and skilful navigator, was born about the year 1539, in Devonshire, and descended of an ancient family. Though a second son, he inherited a considerable fortune from his father. He was educated at Eton, and afterwards at Oxford, where he did not probably continue long. It was intended that he should finish his studies in the Temple; but being introduced at court by his aunt Mrs Catharine Ashley, then the queen's service, he was diverted from the study of w, and commenced soldier. Having distinguished himlf in several military expeditions, particularly in that ainst Newhaven in 1563, he was sent over to Ireland to sist in suppressing a rebellion; and there, for his signal rvices, he was made commander-in-chief and governor ' Munster, and knighted by the lord deputy, Sir Henry dney, upon the first day of the year 1570. He returned on afterwards to England, where he married a rich heirs. Nevertheless, in 1572, he sailed with a squadron of ne ships to reinforce Colonel Morgan, who at that time editated the recovery of Flushing. On his return to ngland he appears to have resumed his cosmographical udies, to which he was naturally inclined; for, in the ear 1576, he published his treatise on the north-west ssage to the East Indies; and as Martin Frobisher saill in the same year, he probably did so in consequence ' this treatise. In 1578 he obtained from the queen a ery ample patent, empowering him to discover and posss in North America any lands then unsettled. He saill to Newfoundland, but soon returned to England withut success; nevertheless, in 1583, he embarked a second me with five ships, the largest of which put back on acunt of a contagious distemper on board. Gilbert landl on Newfoundland on the 3d of August, and on the 5th ok possession of the harbour of St John's. By virtue ' his patent he granted leases to several people; but ough none of them remained there at that time, they ttled afterwards in consequence of these leases, so that e deserves to be remembered as the real founder of our ast American empire. On the 20th of August he again ut to sea on board a small sloop, which on the 29th foundered in a hard gale of wind; and thus perished Sir Humhrey Gilbert, a man of quick parts, a brave soldier, a good athematician, a skilful navigator, and an enterprising enius. We learn also that he was remarkable for his loquence, and much admired for his patriotic speeches oth in the English and Irish parliaments. He wrote A iscourse to prove a Passage by the north-west to Caaia and the East Indies, 1576, which is preserved in akluyt's Collection of Voyages (vol. iii. p. 11). The tyle is superior to that of most of the writers of the age, nd shows the author to have been a man of considerable eading.

GILBERTINES, a religious order so called from St Gilert of Sempringham, in the county of Lincoln, who foundd the same about the year 1148. The monks of this order bserved the rule of St Augustin, and were accounted caons; the nuns observed that of St Benedict. The founder f this order erected a double monastery, or rather two diferent ones, contiguous to each other, the one for men, the ther for women, but separated by a very high wall. St Gilert himself founded thirteen monasteries of this order, viz. our for men alone, and nine for men and women together, hich had in them seven hundred brethren and fifteen hunred sisters. At the dissolution there were about twentyive houses of this order in England and Wales.

GILCHRIST, Dr Ebenezer, an eminent Scotch phyician, was born at Dumfries in 1707. He began the study f medicine at Edinburgh, which he afterwards prosecuted t London and Paris. He obtained the degree of doctor f medicine from the university of Rheims; and in the ear 1732 he returned to the place of his nativity, where e afterwards constantly resided, and continued the pracice of medicine till his death. It may with justice be said, hat few physicians of the past century exercised their rofession in a manner more respectable or more successful han Dr Gilchrist; and few have contributed so largely to he improvement of the healing art. Having engaged in usiness at an early period of life, his attention was wholly evoted to observation. Endowed by nature with a judgment acute and solid, and a genius active and inventive, he soon distinguished himself by departing, in various important particulars, from established but unsuccessful modes of practice. Several of the improvements which he introduced have procured him great and deserved reputation both at home and abroad. His practice, in ordinary cases, was allowed to be judicious, and placed him high in the confidence and esteem of the inhabitants of that part of the country where he lived. But his usefulness was not confined to his own neighbourhood. Upon many occasions he was consulted by letter from the most distant parts of the country. In different collections are to be found several of his performances, which prove that he had something new and useful to offer upon every subject to which he applied himself. But those writings which do him the greatest honour are two dissertations on nervous fevers, in the medical essays and observations published by a society in Edinburgh; and a treatise on the use of sea voyages in medicine, which first made its appearance in the year 1757, and was afterwards reprinted in 1771. Dr Gilchrist died in 1774.

GILD, or Guild. See Guild.

GILDAS, the oldest British historian, and surnamed the Wise, was born in Wales in the year 511. It is uncertain where he was educated; but it appears from his own writings that he was a monk. Some writers say that he went over to Ireland; and others, that he visited France and Italy. They agree however in asserting, that after his return to England he became a celebrated and most assiduous preacher of Christianity. Dupin says he founded a monastery at Venetia in Britain. Gildas is the only British author of the sixth century whose works are printed; they are therefore valuable on account of their antiquity, and as containing the only information we have concerning the times of which he wrote. The only work, however, attributed to him with certainty is his *Epistola de excidio Britanniæ, et Castigatio ordinis ecclesiastici*, London, 1525, in 8vo, Bâle, 1541, in 12mo, and by Gale in his *Rerum Anglicarum Scriptores veteres*, 1684, 1687, in folio. In this production he laments the miseries and almost total ruin of his countrymen, and severely reproves the corruption and profligacy of his age. The first part contains a vague account of events from the Roman invasion to his own times, and on this account is valuable, notwithstanding the inelegance and obscurity of the style. Gildas is also the supposed author of Canons and Regulations of Discipline for the use of Ireland, collected by Dom Luc d'Achery in the ninth volume of his *Specilegia*. The time and place of his death have not been ascertained.

GILDING, the art of spreading or covering over a thing with gold, either in leaf or in liquid. The art of gilding was not unknown amongst the ancients, though it never arrived among them at the perfection to which the moderns have carried it. Pliny assures us that the first gilding seen at Rome was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to gild the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so rapidly, that in a little time you might see all, even private and poor persons, gild the walls, vaults, and other parts of their dwellings.

We need not doubt that they had the same method as ourselves, of beating gold, and reducing it into leaves; though it should seem that they did not carry it to the same extent, if it be true which Pliny relates, that they only made 750 leaves of four fingers square out of an ounce. Indeed he adds that they could make more; that the thickest were called *bracteæ Prænestinæ*, by reason of a statue of the goddess Fortune at Præneste gilt with such leaves; and that the thinner sort was called *bracteæ questoriæ*.

Gilding.

The modern gilders also make use of gold leaves of different thickness; but there are some so fine that a thousand do not weigh above four or five drachms. The thickest are used for gilding on iron and other metals, and the thinnest on wood. But we have another advantage over the ancients in the manner of using or applying the gold. The secret of painting in oil, discovered of late ages, furnishes us with means of gilding works capable of enduring all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies which would not endure the fire, but with the albumen of eggs or size, neither of which will endure the water; so that they could only gild such places as were sheltered from moisture.

The Greeks called the composition on which they applied their gilding on wood *leucophæum* or *leucophorum*; which is described as a sort of glutinous compound earth, serving in all probability to make the gold stick and bear polishing. But antiquaries and naturalists are not agreed as to the particulars of this earth, its colour, and ingredients.

The lustre and beauty of gold have occasioned several inquiries and discoveries concerning the different methods of applying it to different substances. Hence the art of gilding is very extensive, and contains many particular operations and various management.

A colour of gold is given by painting and by varnishes, without employing gold; but this is a false kind of gilding. Thus a very fine golden colour is given to brass and to silver, by applying to these metals a gold-coloured varnish, which, being transparent, shows all the brilliancy of the metals underneath. Many ornaments of brass were varnished in this manner, which is called gold *laquering*, to distinguish them from those which are really gilt. Silver leaves thus varnished are put upon leather, which is then called *gilt leather*. (See LAQUER.)

There are two methods of gilding on wood, which are severally termed size and oil gilding. The leaves of several metals are used for this purpose, viz. gold, silver, mosaic gold, Egyptian gold, Peruvian gold, and Dutch metal. Gold and silver alone are used when the work is to be burnished; the others only for the coarser sorts of oil-gilding, and that rarely, owing to their liability to blacken with the atmosphere, from being merely a composition of the baser metals.

The practical operations are nearly the same with respect to all the different metals; but as various *sizes* are required to prepare the work, we shall describe the manner of procuring them before we describe how they are employed: 1*st*, Strong size; 2*d*, clear size; 3*d*, burnish gold size, and oil gold size.

1*st*, Strong size is prepared from the parings of animal hides: the best, and that in most common use, is known at the tan-works by the name of bate shavings. To one pound of these shavings add a gallon of water, and boil them together for two or three hours, so that when cold they may become a very stiff jelly. After it has been strained it is fit for use. 2*d*, To prepare clear size, take of vellum two ounces, add one pint of water, and boil them for one hour, or until, when cold, they become a stiffish jelly, about half the strength of the above. 3*d*, To make gold size for burnishing, reduce one pound of fine pipe-clay to powder, take one quarter of an ounce of black lead, and half an ounce of French bole, and grind the two together on a painter's stone with water; mix in the clay, and add more water, until it attains the consistency of a thick paste; put in a quarter of an ounce of olive oil; grind the whole, and it is then ready for use.

The tools to be used are the tip, the cushion, and knife. The tip is a broad thin brush, made of the long hairs of the squirrel's tail glued between two cards. The cushion is a board covered with calf leather, the rough side up, and a fold of cotton between.

Warm the strong size, and mix with it the finest washed whitening until it is of the consistency of very thick cream; lay it on the work to be gilded with a sash tool; allow it to dry, and repeat the coats five or six times, allowing it to dry each time. If plain or moulded, take pumice-stone and smooth the work; allow it to dry, and smooth again with fine sand-paper; then take a portion of the gold size (No. 3), and mix it with a part of the clear size (No. 2), in a warm state, until it has been reduced to the consistency of cream; give the work four coats of this, allowing it to dry each time; rub it down with flour-emery paper, and coat again the parts to be burnished: the mat or flat part must be coated with the clear size (No. 2) reduced with equal part of water. Take the gold leaf and spread it on the cushion, cut it with the knife to the size required, take the tip, grease it slightly, to make the gold lift; and having drawn a wetted hair pencil over the part meant to be covered, lift the leaf with the tip and lay it on, repeating this until the whole is covered: allow this to stand for five or six hours, and rub carefully over the parts to be burnished with the burnisher. The burnisher is a piece of smooth pebble fixed into a handle. Any faults in the mat part should be mended with leaf, and coated over with clear size, and then the work is finished.

Oil-gilding.—Oil gold size is made by grinding Oxford ochre with drying oil, adding, when used, a little fat oil (fat oil is procured by spreading a thin film of linseed oil on water, or shaking it in a bottle with oxygen gas).

Work which is not to be exposed to damp or moisture should be prepared in the same manner as for burnishing, and in the place of burnish gold size it should get two coats of strong size (No. 1) a little reduced with water; and when dry-coated with the oil gold size, and allowed to stand till the breath lies on it, then lay the leaf as formerly described, pressing it down with cotton wool; dust it off with a brush, coat it with clear size, and the work is finished.

Out-door work is prepared entirely with oil-paint in place of size, and when dry it is coated with the oil gold size, and gilded in the same manner as described above; but no size is applied on the surface of the gold.

It will readily be perceived that burnish and mat gilding is a more laborious process than gilding in oil, consequently more expensive at the first. It has, however, the advantage over the oil, for inside work, of keeping longer clean, owing to the smoothness of its surface; for the best executed work in oil has a roughness which allows the smoke and dust more readily to adhere. On the other hand, when the work is to be exposed to the weather, oil gilding has a power of resisting its action scarcely to be conceived.

The method of applying gold upon metals is entirely different, and it is done in various ways. One of these is by previously forming the gold into a paste or amalgam with mercury. In order to obtain a small amalgam of gold and mercury, the gold must first be reduced into thin plates or grains, which are heated red hot, and thrown into mercury previously heated, till it begins to smoke. Upon stirring the mercury with an iron rod, the gold totally disappears. The proportion of mercury to gold is generally as six or eight to one. With this amalgam the surface of the metal to be gilded is to be covered; then a sufficient heat is to be applied to evaporate the mercury; and, lastly, the gold is to be burnished with a bloodstone.

This method of gilding by amalgamation is chiefly used for gilding copper, or an alloy of copper, with a small portion of zinc, which more readily receives the amalgam; and it is also preferable for its colour, which more resembles that of gold than the colour of copper. When the metal to be gilt is wrought or chased, it ought to be preiously covered with quicksilver before the amalgam is ap- lied, that this may be easier spread ; but when the surface f the metal is plain, the amalgam may be applied directly o it. It is to be observed that the use of the blood-stone ; now generally abandoned, and a steel burnisher substi- uted for it. The steel burnisher is case-hardened and then olished ; the clearer the polish is, the brighter will the ietal be burnished. The quicksilver or amalgam is made adhere to the metal by means of a little aquafortis, which ; rubbed on the metallic surface at the same time, and by vhich this surface is cleansed from any rust or tarnish that night prevent the union or adhesion of the metals. But ne use of the nitrous acid in this operation is not, as is generally supposed, confined merely to the cleansing the surface f the metal to be gilt, from any rust or tarnish which it may ave acquired, but also greatly facilitates the application f the amalgam to the surface of that metal. In the first lace it dissolves part of the mercury of the amalgam ; and vhen this solution is applied to the copper, the latter me- al, having a stronger affinity for nitrous acid than the mer- ury has, precipitates the mercury upon its surface, in the ame manner as a polished piece of iron precipitates cop- er upon its surface from a solution of blue vitriol. When ne metal to be gilt is thus covered over with a thin pre- ipitated coating of mercury, it readily receives the amal- am. In this solution and precipitation of mercury, the rincipal use of the nitrous acid in the process of gilding ppears to consist. The amalgam being equally spread ver the surface of the metal to be gilt, by means of a brush, ne mercury is then to be evaporated by a heat just suffi- ent for that purpose ; for if it be too great, part of the old may also be expelled, and part of it will run together, d leave some of the surface of the metal bare. Whilst ne mercury is evaporating, the piece should be from time time taken from the fire, that it may be examined, that ne amalgam may be spread more equally by means of a rush, that any defective parts of it may be again covered, d that the heat may not be too suddenly applied to it ; d when the mercury has evaporated, which is known by ne surface having entirely become of a dull yellow colour, ne metal must then undergo other operations, by which ne fine gold colour is given to it. First, the gilded piece metal is rubbed with a scratch brush, composed of brass ire, until its surface be made smooth ; then it is covered ver with a composition called *gilding wax*, and again ex- osed to the fire until the wax be burnt off. This wax is omposed of bees-wax, mixed with some of the following ubstances, viz. red ochre, verdigris, copper scales, alum, triol, borax ; but, according to Dr Lewis, the saline sub- ances alone are sufficient, without any wax. By this peration the colour of the gilding is heightened ; and the fect seems to be produced by a perfect dissipation of me mercury remaining after the former operation. This ssipation is well effected by this equable application of eat. The gilt surface is then covered over with a saline mposition, consisting of nitre, alum, or other vitriolic lt, ground together, and mixed up into a paste with wa- r or urine. The piece of metal thus covered is exposed a certain degree of heat, and then quenched in water. y this method its colour is further improved, and brought earer to that of gold. This effect seems to be produced the acid of nitre (which is disengaged by the vitriolic id of the alum, or other vitriolic salt, during the expo- re to heat) acting upon any particles of copper which ay happen to lie on the gilded surface. Lastly, some art- ts think that they give an additional lustre to their gilt ork by dipping it in a liquor prepared by boiling some llow materials, as sulphur, orpiment, or turmeric. The ly advantage of this operation is, that a part of the yel- w matter, as the sulphur or turmeric, remains in some of e hollows of the carved work, in which the gilding is apt to be more imperfect, and to which it gives a rich and solid appearance.

Iron cannot be gilt by amalgamation, unless, as it is said, it be previously coated over with copper by dipping it in a solution of blue vitriol. At Sheffield and Birmingham the metal is generally first covered with copper, and then gilded. This species of gilding, however, does not present any thing like a good colour, and, besides, it is by no means durable. Iron may also receive a gold coating from a saturated solution of gold in nitro-muriatic acid, or in aqua-regia, mixed with alcohol or spirit of wine, the iron having a greater affinity for the acid, from which it necessarily precipitates the gold. Whether any of these two methods be applicable to use, is uncertain ; but the method commonly employed of fixing gold upon iron is that above mentioned, of burnishing gold leaf upon this metal when heated so as to become blue ; and the operation will be more perfect if the surface has been previously scratched or graved.

Another method is mentioned by authors, of gilding upon metals, and also upon earthen ware, and upon glass ; namely, to fuse gold with regulus of antimony, to pulverize the mass, which is sufficiently brittle to admit that operation, to spread this powder upon the piece to be gilt, and to expose it to such a fire that the regulus may be evaporated, whilst the gold remains fixed. The inconveniences of this method, according to Dr Lewis, are, that the powder does not adhere to the piece, and cannot be equally spread ; that part of the gold is dissipated along with the regulus ; that glass is fusible with the heat necessary for the evaporation of regulus of antimony ; and that copper is liable to be corroded by the regulus, and to have its surface rendered uneven.

On the subject of gilding by amalgamation Dr Lewis makes the following observations. " There are two principal inconveniences in this business ; one, that the workmen are exposed to the fumes of the mercury, and generally, sooner or later, have their health greatly impaired by them ; the other, the loss of the mercury ; for though part of it is said to be detained in cavities made in the chimney for that purpose, yet the greatest part of it is lost. From some trials I have made, it appeared that both these inconveniences, particularly the first and most considerable one, might in good measure be avoided, by means of a furnace of a due construction. If the communication of a furnace with its chimney, instead of being over the fire, is made under the grate, the ash-pit door, or other apertures beneath the grate, closed, and the mouth of the furnace left open, the current of air, which otherwise would have entered beneath, enters now at the top, and passing down through the grate to the chimney, carries with it completely both the vapour of the fuel and the fumes of such matters as are placed upon it : the back part of the furnace should be raised a little higher above the fire than the fore part, and an iron plate laid over it, that the air may enter only at the front, where the workman stands, who will be thus effectually secured from the fumes, and from being incommoded with the heat, and at the same time have full liberty of introducing, inspecting, and removing the work. If such a furnace is made of strong forged (not milled) iron plate, it will be sufficiently durable : the upper end of the chimney may reach above a foot and a half higher than the level of the fire : over this is to be placed a larger tube, leaving an interval of an inch or more all round between it and the chimney, and reaching to the height of ten or twelve feet, the higher the better. The external air, passing up between the chimney and the outer pipe, prevents the latter from being much heated, so that the mercurial fumes will condense against its sides into running quicksilver, which, falling down to the bottom, is there catched in a hollow rim, formed by turning inwards a portion of

Gilding.

the lower part, and conveyed, by a pipe at one side, into a proper receiver.[1]

"Mr Hellot communicates, in the Memoirs of the French Academy for the year 1745, a method of making raised figures of gold on works of gold or silver, found among the papers of M. Dufay, and of which M. Dufay himself had seen several trials. Fine gold in powder, such as results from the parting of gold and silver by aquafortis, is directed to be laid in a heap on a levigating stone, a cavity made in the middle of the heap, and half its weight of pure mercury put into the cavity; some of the fetid spirit obtained from garlic root by distillation in a retort, is then to be added, and the whole immediately mingled and ground with a muller till the mixture is reduced into an uniform gray powder. The powder is to be ground with lemon juice to the consistence of paint, and applied on the piece previously well cleaned and rubbed over with the same acid juice; the figures drawn with it may be raised to any degree by repeating the application. The piece is exposed to a gentle fire till the mercury is evaporated so as to leave the gold yellow, which is then to be pressed down, and rubbed with the finger and a little sand, which makes it appear solid and brilliant; after this it may be cut and embellished. The author observes that, being of a spongy texture, it is more advisable to cut it with a chisel than to raise it with a graver; that it has an imperfection of being always pale; and that it would be a desirable thing to find means of giving it colour, as by this method ornaments might be made of exquisite beauty, and with great facility. As the paleness appears to proceed from a part of the mercury retained by the gold, I apprehend it might be remedied by the prudent application of a little warm aquafortis, which, dissolving the mercury from the exterior part, would give at least a superficial high colour: if the piece is silver, it must be defended from the aquafortis by covering it with wax. Instruments and ornaments of gold, stained by mercury where the gold is connected with substances incapable of bearing fire, may be restored to their colour by the same means.

"The foregoing process is given entirely on the authority of the French writer. I have had no experience of it myself, but have seen very elegant figures of gold raised upon silver, on the same principle, by a different procedure. Some cinnabar was ground, not with the distilled spirit, but with the expressed juice of garlic, a fluid remarkably tenacious. This mixture was spread all over the polished silver; and when the first layer had become dry, a second, and after this a third, was applied. Over these were spread as many layers of another mixture, composed chiefly of asphaltum and linseed oil boiled down to a due consistence. The whole being dried with a gentle heat on a kind of wire grate, the figures were traced and cut down to the silver, so as to make its surface rough; the incisions were filled with an amalgam of gold, raised to different heights in different parts according to the nature of the design; after which a gentle fire, at the same time that it evaporated the mercury, destroyed the tenacity of the gummy juice, so that the coating, which served to confine the amalgam, and as a guide in the application of it, was now easily got off. The gold was then pressed down and embellished as in the former method; and had this advantage, that the surface of the silver under it having been made rough, it adhered more firmly, so as not to be in danger of coming off, as M. Dufay says the gold applied in this way sometimes did. The artist, however, found the process so troublesome, that though he purchased the receipt for a considerable sum, he has laid the practice aside."[2]

Finally, some metals, particularly silver, may be gilt in a different manner. Let gold be dissolved in aqua-regia. In this solution pieces of linen are to be dipt, and burnt to black ashes. These ashes being rubbed on the surface of the silver by means of a wet linen rag, apply the particles of gold which they contain, and which by this method adhere very well. The remaining part of the ashes is to be washed off; and the surface of the silver, which in this state does not seem to be gilt, is to be burnished with a blood-stone, till it acquire a fine colour of gold. This method of gilding is very easy, and consumes a very small quantity of gold. Most gilt ornaments upon fans, snuff-boxes, and other toys of much show and little value, are nothing but silver gilt in this manner.

Gold may also be applied to glass, porcelain, and other vitrified matters. As the surface of these matters is very smooth, and consequently is capable of a very perfect contact with gold leaf, it adheres to them with some force, although they are not of a metallic nature. This gilding is so much the more perfect, that the gold is more exactly applied to the surface of the glass. The pieces are then to be exposed to a certain degree of heat, and burnished slightly to give them lustre.

A more substantial gilding is fixed upon glass, enamel, and porcelain, by applying to these substances powder of gold mixed with a solution of gum-arabic, or with some essential oil and a small quantity of borax; after which a sufficient heat is to be applied to soften the glass and the gold, which is then to be burnished. With this mixture any figures whatever may be drawn. The powders for this purpose may be made, first, by grinding gold leaf and honey, which is afterwards to be washed away with water; secondly, by distilling to dryness a solution of gold in aqua-regia; thirdly, by evaporating the mercury from an amalgam of gold, taking care to stir well the mass near the end of the process; fourthly, by precipitating gold from its solution in aqua-regia, by applying to it a solution of green vitriol in water, or some copper, and perhaps some other metallic substances.

GILEAD, the son of Machir, and grandson of Manasseh, had his inheritance allotted him in the mountains of Gilead, whence he took his name. The mountains of Gilead were part of the ridge which runs from Mount Lebanon southward, on the east of the Holy Land; and they gave their name to the whole country which lies on the east of the sea of Galilee, and includes the mountainous region called in the New Testament *Trachonitis.*

GILIBANTA, a small island in the Eastern Seas, near the coast of Cumbava, situated in long. 119. 36. E. lat. 8. 22. S.

GILL, JOHN, D.D., a Protestant dissenting minister of the Baptist denomination, was the son of Edward and Elizabeth Gill, and was born at Kettering in Northamptonshire, on the 23d November 1697. At a very early period of life his father, who was a deacon of the Baptist church at Kettering, discovered in him an uncommon capacity for learning; and his ability for literary pursuits afterwards appeared by the rapid progress he had made o whatever became the object of his study. He was sent n a grammar-school in the neighbourhood, where he soon urpassed those boys who were much his seniors in age nd also as pupils. He continued till he arrived at his leventh year at this school, where he read most of the atin classics, and likewise made considerable proficiency n the Greek language.

---

[1] Dr Lewis's improvements, however, have been found too complicated, and simpler contrivances have been had recourse to. The following is the method lately introduced, and now in use. A sponge saturated with vinegar is fastened underneath the mouth and nostrils, and a vessel filled with cold water is placed at the vent of the furnace. This vessel attracts the principal portion of the fumes of mercury, and the remainder is attracted by the sponge. But still this is not able to attract all the smoke, and the gilders in large manufactories generally die at an early age.

[2] The process of M. Dufay is a very ancient one, and totally abandoned, or else only had recourse to for the purpose of amusement, or to observe chemical action.

He left the grammar-school, however, early in life. his was occasioned by the imperious conduct of his mas-er, who insisted that the children of dissenting parents hould, with other scholars who belonged to the establishnent, attend him to church on week days during the perormance of divine service. The dissenters considered his requisition as a stretch of power to which his engagenents with them gave him no claim; and as it was virtully making conformity a test by which his pupils were o expect the benefits of tuition, they resented his conuct, and the children of those parents who were in afuent circumstances were removed to seminaries where he same advantages might be obtained without being ubject to the impositions of clerical bigotry. But as the arents of Mr Gill had it not in their power to confer upon im the same privilege, the same steps could not be taken o facilitate his advancement in learning. In order to pave he way, however, for the completion of his studies, efforts vere made by several ministers, of different denominaions, to get him upon one or other of the funds in Lonon. For this purpose specimens of his progress in the ifferent branches of literature were transmitted to the netropolis; but in answer to these applications it was obected that he was too young, and that should he contiue, as it might be expected he would, to make such raid advances in his studies, he would pass through the ommon course before he would be capable of taking care f himself, or of being employed in any public service. But these formidable objections were of no weight with ur young scholar, whose love of learning was unconquerble. Insuperable difficulties, it is true, obstructed the vay in which literary eminence is usually acquired; but hese difficulties could neither repress his ardent desire of nowledge, nor damp the zeal and application with which e had devoted himself to his studies. For though his ime was daily allotted to the business of his father, yet e had so far improved the hours of leisure as to be able, efore he arrived at his nineteenth year, to read all the Greek and Latin authors that fell in his way. He studied ogic, rhetoric, moral and natural philosophy; and learnd the Hebrew language so as to read it with ease, withut any other assistance than Buxtorf's grammar and lexion.

Neither the pursuit of learning, however, nor the other ecessary avocations incumbent on Mr Gill, could eradiate those religious impressions which he had received in arly life. On the 1st of November 1716, he made a pubc profession of his faith before the Baptist church at Kettering, and was baptized the same day by Mr Thomas Vallis. Of this church Mr Gill had not been long a memer before he was called to the work of the ministry; soon fter which, he removed to Higham-Ferrers, with a view o pursue his studies under the direction of Mr Davis; ut his stay at the latter place was interrupted by an nvitation from London in 1719, to preach to the Baptist hurch in Horslydown, over which he was the same year, eing the twenty-second of his age, ordained pastor; and his office he held upwards of fifty-one years.

Mr Gill had not been long in London, before rabbinical earning, of which he had before acquired considerable nowledge, became an object of pursuit. To faciliate his rogress through the intricacies of this labyrinth, he conracted an acquaintance with one of the most learned of he Jewish rabbin. He read the Targums, the Talmud, the Rabbot, their ancient commentaries, the book Zohar, and whatever else of this kind he was able to procure. Of the oriental languages he made himself a complete master; in short, there was no branch of knowledge that could either enlarge or enrich biblical learning, which, however difficult, was not attempted and attained by him; and it may be truly asserted, that in this line he had but few equals, and that the annals of literature do not exhibit many by whom he was excelled.

In 1748, Mr Gill published a commentary on the New Testament, in three volumes folio. The immense reading and learning discoverable in this arduous work attracted the attention of the Marischal College and University of Aberdeen, and procured for him the degree of Doctor in Divinity. He died at Camberwell, on the 14th of October 1771, in the seventy-fourth year of his age.

His works are, A Commentary on the Old and New Testament, in nine volumes folio; A Body of Divinity, in three volumes quarto; The Cause of God and Truth, four volumes octavo; A Treatise concerning the Prophecies of the Old Testament respecting the Messiah; A Dissertation on the antiquity of the Hebrew Language, Letters, Vowel Points, and Accents; and Sermons on the Canticles, folio; besides a great number of sermons and controversial pieces.

GILL, a measure of capacity, containing a quarter of an English pint.

GILLINGHAM, a parish of Dorsetshire, in the hundred of Redlane, 105 miles from London, and five miles from Shaftesbury. It lies on the river Stour, and is the largest parish in the county, being forty miles in circumference. It is a fertile district, producing large quantities of excellent butter. A palace of one of the Saxon kings was erected here, which, by the remains that can be traced, appears to have been of stupendous magnitude and strength. A battle was fought here in 1016, when Edmund Ironside totally defeated a large army of Danish invaders. The population in 1801 amounted to 1873, in 1811 to 1992, in 1821 to 2246, and in 1831 to 2520.

GILLINGHAM, a parish of the county of Kent, in the hundred of Chatham and Gillingham, thirty-two miles from London. It is situated on a hill near to, and commanding a view of, the river Medway, and containing within its limits a part of the town of Chatham, and of Brompton. A large portion of it is covered with those fortifications which form the defences of the important naval arsenal of Chatham. The barracks for the marines consist of a handsome pile of buildings, and are deemed peculiarly healthy for the troops quartered in them. The population amounted in 1801 to 4135, in 1811 to 5135, in 1821 to 6209, and in 1831 to 6734.

GILLY SINDE, a river of Hindustan, in the province of Malwah, which has its source in the Vindhya Mountains, and afterwards flowing in a northerly direction, falls into the Sepra river, which afterwards joins the Chumbul.

GILOLO, one of the Molucca islands, in the Eastern Seas, which is of a large size and very irregular form, consisting of a long mainland, extending in length north and south 220 miles, and composed of four large peninsulas, separated from one another by deep bays. It extends from the latitude of 3. 10. south, to 0. 50. north. The island is generally very fertile, and abounds with bullocks, buffaloes, goats, deer, and wild hogs; but there are few sheep. The sago and fruit-trees flourish here in great abundance; the former yielding to the inhabitants their chief subsistence. This island also produces nutmegs and cloves; but, by the narrow and malignant policy of the Dutch, the trees which produced these spices were rooted up in all places near the sea-coast, or to which there was a ready access by sea. All foreign trade was also discouraged, in order to prevent the smuggling of spices; and the natives were even prohibited, under severe penalties, from manufacturing cloth. These violent edicts, however, the inhabitants contrived to evade, by secretly sending to the other islands for supplies of material. Ossa bay, on the east coast of the island, is an extremely narrow and deep inlet, penetrating about half way through the island. The town of Ossa, situated on the south side of the bay, in longitude 128. 22. east, and latitude 0. 45. north, affords every convenience for ships touching at the island, either for water, provisions, timber, spars, or other articles. There are several other towns in the island, viz. Maba, Patany, and Weda; but being seldom visited by Europeans, they are little known. This island was formerly under the control of the Dutch; but is at present independent of that or any other European nation, and under the government of several independent rajahs or chiefs. A considerable trade is carried on in their own vessels with Amboyna and the neighbouring islands, whence they import cutlery, cloth, China-ware, gold-lace, iron in bars, opium, piece-goods, and steel. The articles imported are nutmegs, cloves, mace, biche-de-mer, bird-nests, tortoise shells, &c.

GILPIN, Bernard, rector of Houghton, distinguished by his extraordinary piety and hospitality, was descended from an ancient and honourable family in Westmoreland, and born in 1517. As he was bred in the Catholic religion, so he for some time defended it against the reformers, and at Oxford held a disputation with Hooper, afterwards bishop of Worcester, and a martyr for the Protestant faith; but he was staggered in another disputation with Peter Martyr, and began seriously to examine the contested points by the best authorities. Accordingly, being presented to the vicarage of Norton, in the diocese of Durham, he soon resigned it, and went abroad to consult eminent professors on both sides; and after three years absence returned, a little before the death of Queen Mary, satisfied with the general doctrines of the Reformation. He was kindly received by his uncle Dr Tonstall, bishop of Durham, who soon afterwards gave him the archdeaconry of Durham, to which the rectory of Effington was annexed. When repairing to his parish, though the persecution was then at its height, he boldly preached against the vices, errors, and corruptions of the times, especially among the clergy, on which a charge, consisting of thirteen articles, was drawn up against him, and presented in form to the bishop. But Dr Tonstall found a method of dismissing the cause in such a manner as to protect his nephew without endangering himself, and soon afterwards presented him to the rich living of Houghton-le-Spring. He was a second time accused to the bishop, and again protected; when his enemies, enraged at this second defeat, laid their complaint before Dr Bonner, bishop of London, who immediately gave orders to apprehend him. Upon this Mr Gilpin prepared for martyrdom; and having ordered his house-steward to provide him a long garment, that he might make a decent appearance at the stake, he set out for London. Luckily, however, he broke his leg on the journey, which protracted his arrival until the news of the queen's death freed him from all further apprehension. Being immediately set at liberty, he returned to Houghton, where he was received by his parishioners with the most sincere joy.

Upon the deprivation of the Roman Catholic bishops, he was offered the see of Carlisle, which he declined; and confining his attention to his rectory, he discharged all the duties of his function in the most exemplary manner. To the greatest humanity and courtesy, he added an unwearied application to the instruction of those under his care. He was not satisfied with the advice he gave in public, but used to instruct in private, and brought his parishioners to come to him with their doubts and difficulties. He had a most engaging manner towards those whom he thought well disposed; nay, his very reproof was so conducted that it seldom gave offence; the becoming gentleness with which it was urged made it always appear as the effect of friendship. Thus, with unceasing assiduity, he employed himself in admonishing the vicious and engaging the well-intentioned; and by these means he in a few years effected a greater change in his neighbourhood than could well have been imagined.

But his hopes were not so much in the existing generation as in the succeeding one. It was an easier task, he found, to prevent vice than to correct it; to form the young to virtue, than to amend the bad habits of the old. He employed much of his time, therefore, in endeavouring to improve the minds of the younger part of his parish, suffering none to grow up in ignorance of their duty, but pressing it as the wisest part to unite religion with labour, and, amidst the cares of this life, to have a constant eye upon the next. He attended to every thing which might be of service to his parishioners. He was assiduous in preventing lawsuits among them. His hall is said to have been often thronged with people, who came to him about their differences. He was not indeed much acquainted with law, but he could decide equitably, and that satisfied them; nor could his sovereign's commission have given him greater weight or authority than his own character secured him.

His hospitable manner of living was the admiration of the whole country. He spent in his family every fortnight forty bushels of corn, twenty bushels of malt, and a whole ox; besides a proportional quantity of other kinds of provision. Strangers and travellers found a cheerful reception. All were welcome who came; and even their beasts had so much care taken of them, that it was humorously said, if a horse were turned loose in any part of the country, it would immediately make its way to the rector of Houghton.

Every Sunday, from Michaelmas till Easter, was a sort of public day with him. During this season he expected to see all his parishioners and their families. For their reception, he had three tables well covered; the first being intended for gentlemen, the second for husbandmen and farmers, and the third for day-labourers. This piece of hospitality he never omitted, even when losses, or a scarcity of provision, made its continuance rather difficult to him. He thought it his duty, and that was a decisive motive. Even when he was absent from home, no alteration was made in his expenses; the poor were fed as usual, and his neighbours entertained.

But notwithstanding all his painful industry, and the large scope he had for it in so extensive a parish, Mr Gilpin thought the sphere of his benevolence too confined. It grieved him extremely to see everywhere, in the parishes around him, so great a degree of ignorance and superstition, occasioned by the shameful neglect of the pastoral cure among the clergy of those parts. The bad consequences resulting from this induced him to supply, as far as he could, what was wanting in others. For this purpose, he used every year regularly to visit the most neglected parishes in Northumberland, Yorkshire, Cheshire, Westmoreland, and Cumberland; and that his own parish might not in the mean time suffer, he was at the expense of a constant assistant. In each place he staid two or three days; and his method was, to call the people about him, and lay before them, in as plain a way as possible, the danger of leading wicked or even careless lives; explaining to them the nature of true religion, instructing them in the duties they owed to God, their neighbour, and themselves, and showing them how greatly a moral and religious conduct would contribute to their present as well as future happiness.

Mr Gilpin's generous and hospitable manner of living as been already noticed. The value of his rectory was bout L.400 a year; an income, indeed, at that time very onsiderable, but yet in appearance very disproportionate o the generous things he performed with it; indeed he ould not have done these, unless his frugality had been qual to his generosity. His friends, therefore, could not ut wonder to find him, amidst his many great and contiual expenses, entertain the design of building and endowng a grammar-school; a design, however, which his exact conomy soon enabled him to accomplish, though the exense of it amounted to upwards of L.500. His school as no sooner opened than it began to flourish; and so reat a number of young people flocked to it, that in a ttle time the town was not able to accommodate them. Ie put himself, therefore, to the inconvenience of fitting p, for that purpose, a part of his own house, where he eldom had fewer than twenty or thirty children. Some f these were the sons of persons of distinction, whom he oarded at easy rates; but the greater part were poor hildren, whom he educated, clothed, and maintained at is own charge. He was at the expense likewise of boardng in the town many other poor children. He used to ring several every year from the different parts where e preached, particularly from Readsdale and Tinedale; laces which he was at great pains in civilizing, and in ooting out that barbarism which every year prevailed ss and less amongst them.

As to his school, he not only placed in it able masters, hom he procured from Oxford, but he himself likewise onstantly inspected it; and, that encouragement might uicken the application of his boys, he always took parcular notice of the most promising. He would call them *is own scholars*, and would send for them often to his partment, and there instruct them himself. One method sed by him to fill his school was a little singular. Whenver he met a poor boy upon the road, he would make ial of his capacity by a few questions, and if he found such as pleased him, he would provide for his educaon. And besides those whom he sent from his own chool to the universities, and there wholly maintained, e likewise gave to others, who were in circumstances to o something for themselves, what further assistance they equired. By these means he induced many parents to llow their children a liberal education, who would not therwise have done so. Nor did Mr Gilpin think it sufcient to afford the means only of an academical educaon to these young people; he endeavoured also to rener it as beneficial to them as he could. He still condered himself as their proper guardian; and he seemd to think himself bound to the public for their being ade useful members of society, as far as it lay in his ower to make them so. With this view he carried on punctual correspondence with their tutors; and made e youths themselves frequently write to him, and give im an account of their studies. So solicitous indeed as he about them, knowing the many temptations to hich their age and situation naturally exposed them, at once every other year he generally made a journey the universities to inspect their behaviour. Nor was is uncommon care unrewarded; for many of his schors became ornaments to the church, and men of exemary piety.

Whenever he heard of any in distress, whether of his vn parish or of any other, he was sure to relieve them. In s walks abroad, he would frequently bring home with him oor people, and send them away clothed as well as fed. e took great pains to inform himself of the circumstances his neighbours, that the modesty of the sufferer might ot prevent his being relieved. But the money best laid out as, in his opinion, that which encouraged industry. It was one of his greatest pleasures to make up the losses of his laborious neighbours, and prevent their sinking under them. If a poor man had lost a beast, he would send him another in its room; or if any farmer had had a bad year, he would make him an abatement in his tythes. Thus, as far as he was able, he took the misfortunes of his parish upon himself; and, like a true shepherd, he exposed himself for his flock. But of all kinds of industrious poor, he was most forward to assist those who had large families; persons in this situation never failed to experience his bounty when they wanted to settle their children in the world.

This benevolent and excellent divine, who merited and obtained the glorious titles of Father of the Poor, and the Apostle of the North, died in 1583, in the sixty-sixth year of his age.

GINGEE, a district in the Carnatic, situated between the twelfth and thirteenth degrees of north latitude. It is bounded on the east by the sea, along which is the travelling road from Madras to Pondicherry. The English had factories here in the middle of the seventeenth century. It is now comprehended in the southern division of the Arcot collectorship.

GINGEE, a town of the Carnatic, and capital of the above district, and a celebrated fortress, which stands on a stupendous rock, and is impregnable by all the ordinary modes of attack. It is said to have been built or improved on an old foundation of the Chola kings, by the son of Vijeya Runga Naik, the governor of Tanjore, in 1442. It was successively strengthened by the Mahommedan kings of Bejapore, who possessed it from 1669 to 1677, and by the Mahrattas, who held it in the year 1698. At this period it was besieged and taken by Zulficar Khan, the imperial general, who appointed Rajpoot governors. They affected independence, and assumed the rank of rajahs. In 1750 it was taken by surprise during a night attack by the French under M. de Bussy; but it surrendered to the British after the capture of Pondicherry in 1761. Like all the other hill forts in India, it is reckoned very unhealthy; and the French are said to have lost about twelve hundred of their number during the ten years they held possession of it; on which account it is garrisoned during the peace by a small number of native troops. Long. 79. 34. E. Lat. 12. 15. N.

GINGERAH, a fortified island on the western coast of India, at the mouth of a river, on the bank of which is situated the town of Dimda Rajepore. This place is celebrated in history, first as being one of the stations of the fleet commanded by the Siddees or Abyssinians, who were first in the service of the kings of Bijapoor, and deserted with their ships in the year 1661 to Aurungzebe; and, second, it was exposed to a long siege by the Mahratta chief Sevagee.

GIOIA, FLAVIO, a pilot or ship-captain, was born at Pasitano, a village situated near Amalfi, about the end of the thirteenth century. During a long period this navigator was generally regarded as the inventor of the mariner's compass; and so precise were the ideas of some writers on the subject, that they fixed the year 1302 or 1303 as the date of the invention. But every one now knows that the claims of Gioia have been disputed; that, according to some, he did not invent, but only improved, the compass; whilst, in the opinion of others, he had nothing whatever to do either with the invention or improvement of an instrument which, in a certain sense, may be said to have changed the face of the world. To render him justice, however, it is necessary to recall the most remarkable opinions which have been expressed on the subject, and, in particular, to indicate the facts by which these opinions are sought to be supported.

Polydore Virgil places the invention of the compass amongst those the authors of which are unknown. *Om-*

nino in aperto non est,[1] says he; and however superficial this writer may be, his testimony is of great weight against Gioia, as he was born in Italy only two hundred years after the celebrated navigator of Amalfi. Several learned men have attributed the invention of the compass to the Phœnicians, to the Tyrians, and to King Solomon respectively. Court de Gébelin is one of those who attribute it to the Phœnicians. Others, misled by an ill-interpreted passage of Plautus, have supposed that the Greeks and Romans were acquainted with the compass. In this number is Abundantius Collina, who, in a memoir entitled *De Acûs Nauticæ Inventore*,[2] has promulgated such a notion. But these opinions have been completely refuted by Turnebus, Bochart, and Dutens; by Trombelli, *De Acûs Nauticæ Inventore*;[3] by Grimaldi, *Sopra il primo Inventore della Bussola*;[4] by Montucla in his *Histoire des Mathématiques*; and more recently by Azuni, in a Dissertation on the Origin of the Compass, printed twice in Italian, and then in French, Paris, 1807, in 8vo. In fact, the ancients knew not the directive virtue of the magnet. The silence of all the authors of antiquity, who have spoken of the loadstone, particularly of Lucretius, Pliny, Claudian, and Plutarch, forms a negative proof of their ignorance of this quality which seems quite insuperable. Gerbert of Auvergne, born about the commencement of the tenth century, and afterwards pope under the name of Silvester II., being desirous, when he was bishop of Magdeburg, to construct a horizontal solar dial, found the north point by the help of an instrument with which he observed the pole star; *in Magdeburg horologium fecit, illud recte constituens, considerata per fistulam quamdam stella Nautarum duce*.[5] Father Costadau, Collina, and others, have thought that, in the instrument here mentioned, they recognized the compass. But Montucla has refuted this erroneous opinion, and shown that the instrument of Gerbert was merely a tube (*fistula*), which he directed towards the pole star in order to determine the meridian line. Evidence more convincing, however, attests that the navigators of the Mediterranean were acquainted with the magnetic needle, and knew how to make use of it more than a century before the time of Gioia.

Albert, surnamed the Great, in his treatise *De Mineralibus*,[6] mentions a passage of a work, erroneously attributed to Aristotle, which he renders in these terms: *Angulus magnetis quidam est, cujus virtus apprehendendi ferrum est, ad zoron, hoc est, septentrionalem; et hoc utuntur nautæ: angulus vero alius magnetis illi oppositus trahit ad aphron, id est, polum meridionalem*. Whether this remarkable passage be found in Aristotle or not is of little importance with reference to the period when Albert lived (he was born in 1193, and died in 1280); indeed it is necessary to go farther back than his time, for the citation must have been made from some work still more ancient; and even if the treatise *De Mineralibus* were not the work of Albert, this would not diminish the importance of the passage which the author, whoever he may be, has therein inserted, and which not only shows that the directive power of the magnet was then known, but that this power was applied by mariners for the purposes of navigation. Besides, the same text is cited by Vincent of Beauvais, in the first part of his *Bibliotheca Mundi*;[7] and this part, entitled *Speculum Naturale*, must have been completed in the year 1250, as appears from book xxvii. chapter 102. Brunetto Latini, in his *Trésor*, composed first in French (Paris, 1260), and then translated by himself into Italian, also speaks of the compass in language not to be mistaken.[8] There is another text which has also become famous in this discussion; we mean that of the *Bible-Guyot*, from verse 622 to verse 658, in which we find the compass clearly indicated under the names of *manière* or *marinière*, *manette* or *marinette*, according to the various readings of the different manuscripts. This text may be seen entire in the *Fabliaux* and *Contes*, published by Barbazan and Méon.[9] The satire, called the *Bible-Guyot*, is generally attributed to Guyot, a French monk of Provins, who must have flourished about the end of the twelfth century, since he appeared at the court of the Emperor Frederick I. in 1181. But supposing this rhythmical piece were, as some have thought, the work of Hugues de Bercy, a contemporary of Saint Louis, this difference would only bring down the date by fifty, or at the most sixty years. Lastly, a passage equally clear in the work of the Cardinal de Vitry, fixes the date beyond all doubt. James of Vitry, a native of Argenteuil, and bishop of Ptolemaïs in Syria, went to Palestine during the fourth crusade, that is, about the year 1204; on his return from this voyage, he discharged the functions of legate of Pope Innocent III. in the army which, in 1210, the Count de Montfort led against the Albigenses; and having again set out for the Holy Land, he returned thence under Honorius III. a considerable time before the death of this pope, and died in the year 1244. But if, as is commonly supposed, he wrote his description of Palestine, which forms the first book of his history, and is entitled *Historia Orientalis*, during his second sojourn in the East, this would fix its composition between the years 1215 and 1220; and, besides, he speaks of a fact which he had observed since the year 1204. Now, in his 91st chapter, he thus expresses himself: *Acus ferrea, postquam adamantem contigerit, ad stellam septentrionalem, quæ vel utaxis firmamenti, aliis vergentibus, non movetur, semper convertitur; unde valde necessarius est navigantibus in mari.* [The iron needle, after contact with the loadstone, constantly turns to the north-star, which, as the axis of the firmament, remains immovable, whilst the other stars revolve; and hence it is essentially necessary to those navigating on the ocean.] The sense of these words presents no difficulty or obscurity. The question is not one relating to a new discovery, but to a usage already established, to an instrument regarded as absolutely necessary to mariners, to a species of knowledge which had in fact become general and common.

As Albert the Great, Guyon, and the Cardinal de Vitry, were all Frenchmen, and as Brunetto Latini composed his work during his stay in France, whilst James of Vitry must ave crossed the Mediterranean in French vessels, the Benedictine authrors of the Literary History of France have ence concluded that the compass is a French invention ; nd, in support of this conclusion, they have referred to the sage (undoubtedly French) adopted by all nations of trang upon the card of the compass a *fleur-de-lis* to indiate the north. This opinion has been adopted by M. zuni, and maintained by all the means which extensive udition could supply, in the dissertation to which we have ready referred. But other writers have claimed for the rabians the honour of this invention. Amongst these may e mentioned Tiraboschi, in his *Storia della Letteratura taliana ;* Andres, in his *Origine e Progressi d'ogni Letratura ;* Bergeron, in his *Abrégé de l'Histoire des Sarrans ;* and Riccioli, in his *Geographia et Hydrographia rermata.* All the writers who have maintained this opinion, owever, rest solely upon vague assertions, and are unable produce any positive proofs. On the other hand, Charn is persuaded that the Arabians received the compass om Europe ; whilst Renaudot has gone so far as to main-in that there exists not any Arabian writing in which ention is made either of the compass, or even of the dictive virtue of the magnet.[1] Nor has any authority been oduced against the latter opinion, except the work of ailak Kaptchaki, entitled, in Arabic, Treasure of Merchants the knowledge of Stones ;[2] and the passage of this writer, iginally discovered by M. Silvestre de Sacy, confirms the inion of Renaudot rather than destroys it, since the auor, who wrote in the year 681 of the hegira, relates a fact which he had been witness in the year 640 [1242 of our a], and since these dates are *posterior* to the times of uyot de Provins and Cardinal de Vitry. Ebn-Iounis, an rabian astronomer, in his *Grand Hakemite Table*, a work mposed in the year 1007 of our era, and published in rench by M. Coussin,[3] also furnishes a negative proof of e most conclusive kind that the Arabians of his time were acquainted with the compass ; for neither among the inruments of which he makes mention, nor among the obrvations which he records, does he ever speak of or allude such a thing in any way. But there always remains tween these two epochs, that is, between the year 1007 d the year 1290, the passage attributed to Aristotle, hich must necessarily have been derived from some Araan author.

[8] His words are, "Pour ce nagent le mariniers à l'enseigne de ces deux étoiles que l'on appelle Tramontaines......et chacun des deux faces [de l'aimant] alse la pointe de l'aiguille à celle tramontaine à que cette face gist." (*Trésor*, lib. i. cap. 113.)

[9] Tome ii. p. 327. It commences with these verses:

> De notre père l'apostoile
> Volsisse qu'il semblast l'estoile
> Qui ne se muet...

and it terminates with the following:

> Molt est l'estoile, et belle et clerè,
> Tiex devroit estre notre père.

The authors who have written on China have attacked e claims of Gioia with most success. Father le Compte, ailla, Father Gaubil in his *Histoire de l'Astronomie Chiise*, and Barrow in his *New Voyage to China*, declare emselves convinced that the Chinese made use of the mpass long before our era. Hager, in a dissertation pubhed in Italian, under the title of *Memoria sulla Bussola ientale*, has developed this opinion, and endeavoured to ove not only that the compass is an invention of the hinese, but that this people transmitted it to us by means their communications with the Arabians. On this hythesis, it appears wonderful that the compass, said to have en in use in the Indian Sea one or two thousand years fore Christ, should not have been known either to the yptian navigators under the Ptolemies, or to the Greeks Constantinople in the middle ages. Chardin had left the estion in doubt. But M. de Guignes goes farther, and aintains that the sources whence Father Gaubil derived s information are modern romances ; and he censures at historian for having supposed that he had detected e mention of a compass in texts which are recognised as ulous.[4] Nevertheless, it cannot now be doubted that e Chinese were acquainted with the compass, if not at the early epochs of which Father Gaubil speaks, at least long before the Europeans ; and great weight has been given to this opinion by the judgment which Barrow, Macartney, and other recent travellers, have formed on the subject.

But be this as it may, the writers who have attributed the invention to Gioia are innumerable. Amongst others, Grimaldi, a learned Neapolitan, has collected in favour of his countryman, in the dissertation which we have already cited, a number of positive authorities, and has supported them with very imposing names. Nor can it be dissembled that, during a long period, the opinion of all Europe supported the claim of Gioia, and that there must have been some important fact or circumstance to produce an assent so general in his favour. What, then, is the precise title which the mariner of Amalfi possesses to public gratitude? Father Fournier appears to have resolved this problem in his *Hydrographie ;*[5] and Montucla, adopting the opinion of Fournier, has developed it with a clearness calculated to satisfy every mind. The compass used in the Mediterranean during the twelfth and thirteenth centuries consisted only of a magnetic needle, which was made to float in a vase or bason by means of two straws or a bit of cork, which supported it on the surface of the water. Such is the description which the author of the *Bible-Guyot* has given of the instrument ; and hence the names of *calamite* or of *grenouille* (frog), under which it is designated in some authors. The compass known to the Arabians, in the thirteenth century, according to Bailak Kaptchaki, was no other than that here described. " It is easy to perceive," says Montucla, " how inconvenient this was, and how often the agitation of the sea would render it useless.....But the Amalfitans imagined the convenient suspension which we now employ, by placing a magnetised needle on a pivot which permits it to turn to all sides with facility. It is not known that at first they went farther than this. Afterwards it was attached to a card divided into thirty-two points (*rumbs de vent*), and named *Rose des Vents ;* and then the box containing it was suspended in such a manner that, whatever motion the vessel might experience, it would always remain horizontal. The English claim, *jure an injuria*, this addition to the compass, but on what ground I know not, having seen no proof in support of such a pretension." If the import of the verse of Antonius Panormitanus, which is considered as one of the strongest proofs in favour of the claim of Gioia, be examined with attention, it will perhaps be observed that allusion is made, not to an invention, but a great and important improvement. The verse in question is as follows :

> Prima dedit nautis *usum* magnetis Amalphis.

The poet does not appear to affirm that the town of Amalfi had given to mariners the *knowledge* of the magnetic needle, but only that it had given, or rather facilitated, the *usage* thereof.

Such, then, appears to have been the merit of Gioia, namely, having rendered truly useful an instrument of which, though previously known in an unimproved state, little or no use could then be made. The timidity of pilots, in the twelfth and thirteenth centuries, when they were already in possession of the *calamite* or *grenouille*, and the boldness which they displayed when provided with the compass of Amalfi, evidently attest the importance of the service rendered to modern navigation by Gioia. To improve in this manner is really to invent. It is possible that the French may have added the *Rose des Vents*, or card, to the suspended needle of Gioia, which would account for the *fleur-de-lis* being employed to indicate the north, as already mentioned. It is also possible that the English may have conceived the idea of including the needle, its pivot, and the card, in a *box* or *boxel*, whence probably the names of *bussola* and *boussole*. The Germans, moreover, claim the names of the winds, East, South, North, West, and even the name of the compass. But these particularities are of little importance. What appears to be established is, that the discovery of the directive virtue of the magnet was made anterior to Gioia; that, before his time, navigators both in the Mediterranean and the Indian Seas employed the magnetic needle; but that, by a very important improvement, in the suspension of the needle, Gioia is entitled to be considered as the real inventor in Europe of the compass such as we now possess it. No history of the life of this navigator is known. Some writers call him Giri; but the name of Gioia is that most generally adopted. Musanzio, in his *Tables Chronologiques*, complains that Vossius and other learned men call him Giri, and describe him as a native of Melfi, "instead," says he, "of Gioia of Amalfi, who invented the compass in the year 1303."[1] (*Biographie Universelle.*) (A.)

GIORGIONE, or Giorgio Barbarelli, an eminent painter, was born at Castelfranco, near Trevigi, in 1478. He learned the rudiments of his profession from Giovanni Bellini at Venice, and is said to have derived his first notions of the force of well-adapted lights and shadows, by carefully studying the works of Leonardo da Vinci. Giorgione was one of the first of the Venetian school who broke through the timid and constrained style to which the art was confined at the time of Bellini, and introduced a freedom of outline, a boldness of handling, and a new and animated manner of colouring, unknown before him. De Piles remarks, "that it is a matter of wonder to consider how, all of a sudden, he soared from the low and dry manner of Bellini's colouring, to the supreme height to which he raised that lovely part of painting, by joining extreme force with extreme sweetness." Yet, as Pilkington observes, when we reflect that nature and Da Vinci were his models, and that he had a genius happily qualified to study them judiciously, we may more easily account for that excellence by which he was distinguished. His pictures were much admired by Titian, who copied his style, and improved upon his effects of chiaro-oscuro. His untimely death prevented his acquiring so extensive a celebrity as Titian did; but, as Phillips observes, "in the race of rivalship between these extraordinary artists, it seems probable, had Giorgione's life been prolonged, he might have surpassed Titian in splendour and vivacity, both of colour and of execution." Several of Giorgione's grand compositions in fresco have perished, and those which remain are so materially injured that little of their original beauty is discernible. His easel pictures were few, and now, on account of their scarcity as well as merit, are exceedingly valuable.

In the department of portrait painting Giorgione may be ranked with the greatest masters. His figures are justly esteemed for their grace, dignity, expression, and truth of character. His carnations have more the appearance of real flesh than of being a fine imitation of it. The landscapes of this artist are also admirable. Of his oil pictures the principal are, Christ bearing his Cross, in the church of St Roch at Venice; at Trevigi, St Mark appeasing the Tempest; in the Monte di Pieta, a Dead Christ; and at Milan, the Finding of Moses. Giorgione died of the plague, in the prime of life, in 1511. (Z. Z.)

GIRALD, Barry, or *Giraldus Cambrensis*. See Barry.

GIRALDI, Lilio Gregorio, an ingenious critic, and one of the most learned men modern Italy has produced, was born at Ferrara in the year 1479. He was at Rome when it was plundered by the Emperor Charles V.; and having thus lost all he had, and being at the same time tormented by the gout, he struggled through life with ill fortune and ill health. He nevertheless wrote a number of works, which were collected and published at Basil, 1580, in two vols. folio, and at Leyden in 1696. Authors of the first rank have bestowed the highest eulogies on Giraldus, particularly Cassaubon and Thuanus.

GIRAR, a fortress of Hindustan, in the province of Malwah, belonging to the Mahrattas. Long. 79. 18. E. Lat. 24. 23. N.

GIRDERS, in *Architecture*, the largest pieces of timber in a floor. Their ends are usually fastened into the summers or brest-summers; and the joists are framed at one end to the girders.

GIRDLE, a belt or band of leather or other matter, tied about the reins, to keep that part more firm and tight.

It was anciently the custom for bankrupts and other insolvent debtors to put off and surrender their girdle in open court. The reason of this was, that our ancestors used to carry all their necessary utensils, as purse, keys, and the like, fastened to the girdle; and hence the girdle became a symbol of the state, or condition of the individual. History relates that the widow of Philip I. duke of Burgundy, renounced her right of succession, by putting off her girdle upon the duke's tomb.

The Romans always wore a girdle to tuck up the tunica when they had occasion to do any thing; and this custom was so general, that such as went without girdles, and allowed their vestments to hang loose, were reputed idle and dissolute persons.

Maiden's or *Virgin's* Girdle. It was a custom amongst the Greeks and Romans for the husband to untie his bride's girdle. Festus relates, that it was made of sheep's wool, and that the husband untied it in bed; he adds, that it was tied in the Herculanean knot, and that the husband unloosed it, as a happy presage of his having as many children as Hercules, who at his death left no less than seventy behind him.

The poets attribute to Venus a particular kind of girdle called *cestus*, to which they annexed the faculty of inspiring the passion of love.

GIRGENTI, a province or intendancy in the island of Sicily, comprehending, besides the Vale of Mazzara on the continent, the islands of Pantalaria and of Lampedosa in the Mediterranean Sea. It is divided into the three districts of Girgenti, Bivona, and Sciacca, and contains 288,877 inhabitants. The capital, which bears the same name, is a city near the sea, on an elevated spot, but watered by the river whose name it has taken. It contains a cathedral and several other churches, 2844 houses, and 14,882 inhabitants. The haven, which is about four miles from the city, is neither deep nor capacious; but being the only one on the southern coast of Sicily, it is a considerable resort for vessels, who repair to it to procure cargoes of wheat, barley, almonds, pistachio nuts, soda, and sulphur, which commodities are abundantly produced in the vicinity. There are in the neighbourhood many remains of remote antiquity, illustrative of the ancient state of this city, which is said to have once contained 300,000 souls. Long. 13. 43. E. Lat. 37. 23. N.

GIRONS, St, an arrondissement in the department of Arriège, in France, having an extent of 603 square miles. It is divided into six cantons and eighty-two communes, and contains 79,084 inhabitants. The chief place is a town of the same name, in a valley watered by the Salat. There re some manufactories of woollen goods, and also some anneries. The population amounts to 2504. Long. 1. . E. Lat. 42. 58. N.

---

[1] Table xxxviii. p. 219.

GIRONDE, a department in the south-west of France, reated out of the ancient principality of Guienne. It is ounded on the north and north-east by the department of he Lower Charente, on the east by those of Dordogne and f Lot-Garonne, on the south by the Landes, and on the est by the ocean. It comprehends 4406 square miles, r, according to the Royal Almanac, 1,082,520 hectares. he civil divisions are six arrondissements, forty-eight antons, and 580 communes, containing a population of 54,225 persons. The whole department is a fine level lain, excepting that on the eastern side there are some entle elevations. That division consists of a soil composed f broken tuffstein, fertile sand, and calcareous matter, nd is well cultivated and highly productive; on the west- rn side, and especially towards the south of the depart- ent, the land is either a morass or barren sands, where, or leagues together, no human habitation is visible, and othing to be seen but a few wandering sheep, some cork- rees, and numerous fir-trees. The latter seem to flourish, nd to yield large quantities of turpentine, pitch, and tar.

None of the departments of France is better watered han the Gironde; most of the streams, which are nume- ous, discharge their water into that river which gives its ame to this division of the country. Several of these ivers are navigable, and by their means fuel is conveyed om the woods, which cover one tenth of the surface, to e several cities whose consumption requires it. The hief object of cultivation is the vine; the wine is chiefly ed, known by the names of Medoc, Haut-Brion, St Emil- an, Latour, Lafitte, and Chateaux-Margaux, but by the eneric names of Bordeaux or claret. The most valued hite wines are known as Carbonnieux, Serons, Graves, arsac, Prignac, Sauterne, Baume, and Sainte-Croix-du- ont. The management of the grapes, as well as of the ine, is well understood; and the produce of the vineyards, esides wine, is very considerable in brandy, liqueurs, pirits of wine, and vinegar.

The corn of the department is insufficient for the con- umption; and large quantities, chiefly of rye, are brought om other districts for the maintenance of the poor. here are few horses bred or kept, and the plough is for e most part worked by oxen, which, as well as the cows, re of an indifferent race. The sheep are not numerous, nd commonly afford meat and wool of an inferior quality. esides grapes, the other fruits are abundant, especially hestnuts, almonds, and figs. The other products of the il are cork, stone coal, turf, hemp, and flax. There are mines except those of iron, which yield but little. Table lt is made on the coast, sufficient for the consumption in e œillets of St Vivian, which produce 1200 tons annually. he manufacturing industry is extensive as to the num- er of articles fabricated, but confined chiefly to the city Bordeaux, the capital. The principal goods are linens d cottons, snuff, glass, china and earthen ware, dyestuffs, ather, ironmongery, cordage, and sailcloth. The com- erce exclusively from Bordeaux is extensive, as well the French colonies as to other parts of the world, to hich native commodities are exported, and the produc- ons of such countries returned.

GIROUT, a town of Hindustan, in the province of Alla- bad, and district Etawah. Long. 78. 44. E. Lat. 27. 3. N.

GISBOROUGH, a market-town of the north riding the county of York, in the wapentake of East Langbo- ugh. It is situated at the mouth of the river Tees, here a bay is formed, having good anchorage for ships. his place worked some mines of alum; but the discovery others of greater richness has caused them to be given up. A priory once stood here, richly endowed, but there are no other remains of it except the superb arch of the east window. The narrow vale in which the town stands is highly fertile. The market is held on Saturday, and is well supplied. It is 248 miles from London. The population amounted in 1801 to 1719, in 1811 to 1834, in 1821 to 2180, and in 1831 to 2210.

GITTITH, a Hebrew word occurring frequently in the Psalms, and generally translated *wine-presses*. The conjectures of interpreters are various concerning this word. Some think it signifies a sort of musical instrument; others, that the psalms with this title were sung after the vintage; and others, again, that the hymns of this kind were invented in the city of Gath. Calmet is rather of opinion that it was applied to the class of young women or songstresses of Gath by whom they were sung. Dr Hammond thinks that the psalms with this title were all set to the same tune, and made on Goliath the Gittite.

GIURGEWO, a city of the Turkish province of Nicopoli. It stands on the northern bank of the Danube, and in the principality of Wallachia, but the garrison is Turkish. It has a strong fortress, and the city itself is fortified. The inhabitants amount to 7000, Greeks, Armenians, and Wallachians, with very few Turks, excepting the military, who chiefly reside within the fortress of Turn, which commands the city. Lat. 43. 52. 45. N.

GLACIERS, a name given to extensive fields of ice amongst the Alps. Mr Coxe observes of these mountains in general, that they are composed of many parallel chains, the highest of which occupy the centre, and the others gradually diminish in proportion as they recede from thence. The central chain appears covered with pointed rocks, all parts of which, that are not absolutely perpendicular, lie hid under perpetual snow and ice even in summer. On each side of this ridge are fertile and cultivated valleys, interspersed with numerous villages, and watered by numerous streams. The elevated peaks of the central chain are covered with snow; but their declivities, excepting those which are extremely steep, have all a covering of ice as well as snow; the intermediate parts being filled with vast fields of ice, terminating in the cultivated valleys above mentioned. The same phenomena, though on a smaller scale, occur in those chains which are at a distance from the principal one. In those which are most remote, no ice, and scarcely any snow, is observed, unless upon some of the most elevated summits; and the mountains diminishing in height and ruggedness, appear covered with verdure, until at last they terminate in small hills and plains.

Thus the glaciers may be divided into two sorts; one occupying the deep valleys situated in the bosom of the Alps, and distinguished by the name of ice valleys; the other being those which clothe the declivities and sides of the mountains. These two kinds of glaciers are distinguished by Mr Coxe into the upper and lower glaciers.

The lower glaciers are by far the most considerable, some of them extending several leagues in length. They do not communicate with each other, as has been generally supposed, few of them being parallel to the central chain; but, stretching mostly in a transverse direction, they are bordered at the higher extremity by inaccessible rocks, and at the lower extend into the cultivated valleys. The thickness of the ice varies in different parts. In the Glacier des Bois, which extends more than fifteen miles in length, and upwards of three in breadth, Saussure found it generally from eighty to a hundred feet; but he was credibly informed, that in some places it was not less than six hundred feet, and even more. These vast masses of ice usually rest on an inclined plane; where, being pushed forward by their own weight, and but weakly supported by the rugged rocks beneath them, they are intersected by large crevices, and have an appearance of walls, pyramids, and the like, according to the position of the eye in viewing them. In those parts, however, where they lie upon even ground, or have only a gentle inclination, the surface of the ice is nearly uniform, the crevices being few and narrow, and the glacier being crossed by travellers on foot without any difficulty. The surface of the ice is rough and granulated, so that people may walk upon it, excepting at such places as have a steep descent. It is opaque, full of small bubbles about the size of a pea, very porous, and greatly resembles a mixture of snow and water congealed. A vast quantity of stones and earth falls down from the mountains upon the glaciers, and is by them thrown off on each side according to the descent of the ice. The place upon which these rest is harder and more elevated than the rest of the ice, and is very difficult to walk upon; the earth is likewise laid upon them in such regular heaps, that it appears to have been done by art. This collection of earths and stones is termed by the natives the *moraine*.

The upper glaciers may be subdivided into those which cover the summits, and those which extend along the sides of the Alps. Those upon the very summits, however, though they have the appearance of ice, are not so in reality, but consist entirely of snow hardened by the extreme cold. Saussure found that which covered the top of Mont Blanc to be penetrable, though with difficulty, by a stick; but below this hard crust was a soft snow without coherence. The sides are covered with a mixture of ice and snow, produced by the power of the summer sun in dissolving the snow, which afterwards congeals into hard ice.

Several conjectures have been hazarded concerning the formation of these extraordinary bodies of ice. Coxe agrees with Gruner in opinion, that they are produced by the continual dissolution of the snow in summer, and its congelation by the succeeding frosts. Hence, on the summits of the mountains, where the sun has very little power, the glacier is soft, and contains no ice; but as we descend the mountains the consistence becomes firmer, because there is a considerable mixture of snow water, the congelation of which augments the hardness; and in the valleys, the glacier is hardest of all, because the portion of water is there much superior to that of the snow. Hence it seems plain that the glaciers derive their origin from the melting of the snow on the upper parts of the mountains, and the congelation of the water as it advances; and to this cause Saussure adds the quantity of snow which often rolls down into the valleys, and congeals along with the water just mentioned.

GLACIS, in building, an easy gradual slope or declivity.

Glacis, in *Fortification*, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champaign or field.

GLADBACH, a town of Prussia, in the government of Cleves, and the capital of a circle of the same name. It is a place which has grown up in a few years to great manufacturing prosperity. It makes large quantities of linen and cotton goods, and many silks; and though within the town the inhabitants do not exceed 2000, yet the villages in contact with it, and forming the suburbs, contain more than 5500 persons.

GLADIATORS, in *Antiquity*, persons who fought chiefly in the arena of the amphitheatre at Rome, for the entertainment of the people. The gladiators were generally slaves, and fought from necessity; though sometimes freemen took to the same profession, like our prize-fighters, for a livelihood. The Romans borrowed this cruel diversion from the Asiatics; and some suppose that there was policy in the practice, the frequent combats of gladiators tending to accustom the people to despise danger and death.

The origin of these combats seems obvious. From the earliest times it had been the custom to sacrifice captives, or prisoners of war, to the manes of the great men who had died in battle. Thus Achilles, in the *Iliad* (lib. xxiii.), sacrificed twelve young Trojans to the manes of Patroclus; and in Virgil (lib. xi. ver. 81), Æneas sent captives to Evander to be sacrificed at the funeral of his son Pallas. But in process of time they came also to sacrifice slaves at the funerals of all persons of condition; and this was even esteemed a necessary part of the ceremony; but as it would have appeared barbarous to massacre them like beasts, they were appointed to fight with each other, and to endeavour to save their own lives by killing their adversary. This seemed somewhat less inhuman, because there was a possibility of avoiding death, by an exertion of skill and courage. The profession of gladiator thus became an art; and hence arose masters of the art, men learned in fighting and exercise. These masters, whom the Latins called *lanistæ*, bought slaves to be trained up to this cruel trade, and afterwards sold them to such as had occasion to present the people with so horrible a show.

The exhibitions were at first performed near the sepulchre of the deceased, or around the funeral pile; but they were afterwards removed to the circus and amphitheatres, and became ordinary amusements. The first show of gladiators, called *munus gladiatorium*, was, according to Valerius Maximus, exhibited at Rome by Marcus and Decius Brutus, upon the death of their father, in the year of the city 490. On this occasion there were probably only three pairs of gladiators. In 537 the three sons of M. Æmilius Lepidus the augur, who had been thrice consul, entertained the people with the cruel pleasure of seeing twenty-two gladiators fight in the forum. In 547, the first Africanus diverted his army at New Carthage (Carthagena), with a show of gladiators, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In process of time the Romans became so fond of these bloody entertainments, that not only the heir of any great and rich citizen lately deceased, but all the principal magistrates, presented the people with shows of this nature, to procure their favour. The ædiles, prætors, consuls, and, above all, the candidates for offices, made their court to the people by entertaining them frequently with these fights; and even the priests were sometimes exhibitors of these barbarous shows; for we meet with the *ludi pontificales* in Suetonius (*August.* cap. 44), and with the *ludi sacerdotales*, in Pliny (*Epist.* lib. vii.). As for the emperors, it was so much their interest to ingratiate themselves with the populace, that they obliged them with combats of gladiators upon almost all occasions; and as these multiplied, the number of combatants likewise increased. Accordingly, Julius Cæsar, in his ædileship, diverted the people with the exhibition of three hundred and twenty couples. Titus exhibited a show of gladiators, wild beasts, and representations of sea-fights, which lasted a hundred days; and Trajan continued a solemnity of this nature for a hundred and twenty-three days, during which time he brought out a thousand pairs of gladiators. Before this time, and under the republic, the number of gladiators was so great, that when the conspiracy of Catiline broke out, the senate ordered them to be dispersed into the garrisons and secured, lest they should join the disaffected party.

These sports at length became so common, and their consequences in a variety of respects proved so dangerous, that Cicero caused a law to be enacted that no person should exhibit a show of gladiators within two years before he appeared as a candidate for any office. Julius Cæsar gave orders that only a certain number of men of this profession should be in Rome at a time; Augustus decreed that only two shows of gladiators should be presented in a year, ators

nd never above sixty couples of combatants in a show; nd Tiberius provided by an order of senate, that no per- on should have the privilege of gratifying the people ith such a solemnity unless he was worth 500,000 ses- erces. The same exhibitions were also regulated by Ner- a. The Emperor Claudius restrained them to certain ccasions; but he soon afterwards annulled what he had ecreed; private persons began to exhibit them as usual, nd some carried the brutal satisfaction so far as to have nem at their ordinary feasts.

The master of the gladiators made them all swear that ney would fight to death; and, if they failed, they were ut to death by fire, swords, clubs, whips, or the like. It as a crime for the wretches to complain when they were ounded, or to ask for death or seek to avoid it when vercome; but it was usual for the emperor or the people grant them life when they exhibited no signs of fear, ut waited the fatal stroke with courage and intrepidity. ugustus even decreed that life should always be granted nem.

From slaves and freemen the inhuman sport at length pread to people of rank and condition; so that Augustus as obliged to issue an edict providing that none of the enatorian order should become gladiators; and soon after- ards he imposed the same constraint on the knights. evertheless Nero is related to have brought upwards of ur hundred senators and six hundred Roman knights pon the arena; though Lipsius supposes both these num- ers to be falsified, and not without reason reduces them forty senators and sixty knights. But Domitian refined n the practice of Nero, and exhibited combats of women the night time.

Constantine the Great is said to have first prohibited ne combats of gladiators in the East; at least he forbade nose who were condemned to death for their crimes eing employed in these exhibitions; and there is still xtant an order to the *præfectus prætorii*, dated at Bery- us in Phœnicia the 1st of October 325.

The Emperor Honorius forbade them at Rome on occa- on of the death of Telemachus, who coming from the East Rome at the time of one of these spectacles, went down to the arena, and used all his endeavours to prevent the ladiators from continuing the sport; upon which the spec- tors of the carnage, fired with indignation, stoned him to eath. It must be observed, however, that the practice as not entirely abolished in the West before the time of heodoric king of the Ostrogoths. Honorius, on the oc- sion first mentioned, had prohibited them; but the pro- ibition does not seem to have been enforced. Theo- oric, in the year 500, finally abolished them.

Some time before the day of combat, the person who resented the people with these shows gave notice of his ntention by programmes or bills, containing the names f the gladiators, and the marks by which they were to e distinguished; for each had his peculiar badge, which as commonly a peacock's feather, as appears from the choliast of Juvenal on the 158th verse of the third satire, nd also from Turnebus (*Advers.* lib. ii. cap 8). They lso gave notice how long the shows would last, and how nany couples of gladiators were to exhibit; and it even ppears, from the seventh satire of the second book of Ho- ace, that they sometimes made representations of these nings in painting, as is practised among us by those who ave any thing to exhibit at fairs.

The day being come, they began the entertainment by ringing two kinds of weapons; the first being staves or ooden foils, called *rudes*, and the second effective wea- ons, as swords, poniards, and the like. The first were alled *arma lusoria*, or *exercitoria*; the second *decretoria*, s being given by decree or sentence by the prætor, or by nim at whose expense the spectacle was exhibited. They began to fence or skirmish with the first, which usually formed the prelude to the battle; and from these, when well warmed, they advanced to the second at the sound of the trumpets, with which they fought naked. Then they were said *vertere arma*. The terms of striking were *petere et repetere*; of avoiding a blow, *exire*: and when one of the combatants received a remarkable wound, his adversary or the people cried out, *Habet*, or *hoc habet*. The first part of the engagement was called *ventilare, præludere*; and the second, *dimicare ad certum*, or *versis armis pugnare*; and some authors think, with much probability, that it is to these two kinds of combat that St Paul alludes in the passage (1 Cor. ix. 26, 27) where he says, "I fight not as one that beateth the air; but I keep my body, and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life; it was the people during the time of the republic, and the prince or people during the time of the empire, who were alone empowered to grant this boon. The reward of the conqueror was a branch of palm tree, and a sum of money, probably collected amongst the spectators; sometimes they gave him his congé, or dismissed him by putting one of the wooden foils or *rudes* in his hand; and sometimes they even granted him his freedom, putting the pilæus on his head. The sign or indication by which the spectators showed that they granted the favour, was *premere pollicem*, which M. Dacier takes to be a clenching of the figures of both hands between one another, and so holding the two thumbs upright, close together; and, when they desired to have the combat finished and the vanquished slain, *verterunt pollicem*, they bent back the thumb, as we learn from Juvenal. (Sat. iii. ver. 36.) The gladiators challenged or defied each other by showing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people. *Victi ostensam digiti veniam a populo postulabant*, says the old scholiast on Perseus.

Glamorganshire.

GLAMORGANSHIRE, a county of South Wales, stretching, in a circular line, along the northern shore of the Bristol Channel, from east to west about forty-two miles, and extending to the mountains in some parts to the distance of twenty-two or twenty-three miles. It is bounded on the north by Caermarthen and Brecknock, on the east by Monmouthshire, and on the south and west by the Bristol Channel. Its whole area is 822 miles, or 526,080 statute acres, in which are included the watercourses, roads, and sites of buildings, which occupy a large surface.

The county may be divided into two districts of a very opposite character, according to the nature of the soil, rather than into those ten hundreds by which its parts are politically denominated. About one half the county, on the sea-shore, is rich and fertile land, and produces excellent crops of wheat, oats, beans, and barley. The soil is generally of moderate consistence, and of a loamy nature, some parts being mixed with clay, others with sand, and almost all resting on a calcareous substratum. It is easily ploughed, very friable, and, when laid down in grass, yields excellent herbage, by which many cattle are fattened, and much good butter is made. The manure principally used is lime, which is rendered very cheap from the vicinity of coals to the limestone district.

The inland part of the county rises gradually from hills to mountains, and in that district the agriculture is in a very backward state. The soil between these hills and mountains is composed generally of a black peat, but sometimes of a brown gravelly earth. Lime applied to the former is beneficial for a few years, but its good effect then ceases; and having but little cattle to make manure, and that manure being neglected to be preserved with due

Glamorganshire.

care, the agricultural produce of the district is insufficient for the subsistence of the inhabitants. On some of the mountain farms the land is sowed with corn as long as it will yield any increase without fallow or manure, and when so far exhausted it is left without cultivation for many years. Much of the unenclosed mountain tract is devoted wholly to feeding sheep, and the occupiers of land around them having rights of common without stint, so overstock them, that the animals seldom attain their full growth; but when removed to better pasture, and fattened, their mutton is excellent. The farms are mostly of very small value, varying in rent from L.5 to L.200 annually; the average of the whole is not L.50, though in many instances the rent has been tripled, and even quadrupled, within the last twenty years. The ploughing is generally executed by oxen, and their ploughs being of clumsy construction, sometimes six or eight are used to perform the work, and yet perform it ill; in some cases two, in others four, are harnessed to plough with two horses before them. The most commendable part of the rural economy of the county is the construction of the houses, barns, and other farming erections. These are solidly and substantially built, and being uniformly white-washed on the outside, have a clean and neat appearance.

The agriculture of this county, valuable as it is in the more southern part, is the least productive source of its riches. The greater part of it abounds with minerals, which, owing to the great extension of good roads, of navigable canals and railways, within the last few years, have become a most important source of wealth. The northern and middle parts of the county comprehend a portion of that great mineral tract which begins at Pontypool in Monmouthshire, and terminates at St Bride's Bay in Pembrokeshire. The exterior stratum or boundary consists of a bed of limestone, within which are contained all the strata of the other minerals in the following position. On the north side of a line drawn from east to west through the middle of the district, all the strata rise gradually to the north, and on the south side of the same line they rise to the south till they come to the surface, except at the east end, where they rise to the eastward. In the centre of this tract, the iron and coal mines in the vicinity of Myrthr-Tydvil are both the richest and most abundant. The whole of the coal is at the depth of 440 feet beneath the surface of the ground, which is composed of argillaceous strata, with occasional veins of hard rock. The coal is about fifty-two feet deep, the thickness of the veins varying from twelve inches to nine feet in thickness. The ironstone lies under the stone at a depth of about 108 feet, and is separated by argillaceous earth and stone into eighteen different veins, each about four feet ten inches in thickness. When this ore is smelted, it yields iron to the amount of three tenths of the weight of the ore.

Coal is found in vast quantities both in the north and south divisions of the county, but of different natures. That in the south is of the bituminous kind, or coaking coal, like the coals of Newcastle. That of the north (when large, called stone-coal and small culm) is difficult to kindle, burns slowly, but emits an intense heat with little or no smoke, and without being distended. This latter is principally used by the maltsters and lime-burners.

Although the abundance and excellence of the coal and iron have caused the erection of blast-furnaces in many parts of the county, yet the largest and most numerous are those near the recently-built town of Myrthr-Tydvil, which, within a few years, has grown up from an obscure village to be the most populous village in the whole principality of Wales, and contained, in 1811, 11,000, and in 1831, 22,000 inhabitants.

There are seventeen blast-furnaces near this place, each of which can make from 100 to 180 tons of iron weekly. The most extensive of the works, that of Cyfartha, belonging to Messrs Crawshay and Company, produce annually upwards of 20,000 tons of pig-iron, and somewhat more bar-iron. The fires of the furnaces are blown by a steam-engine of fifty horse power, and an overshot wheel of fifty feet in diameter, which requires twenty-five tons of water each minute to keep it at work. The number of men employed at Messrs Crawshay's work is from 1500 to 2000, making, with their families, more than three thousand persons, whose yearly wages amount to more than L.140,000.

The next considerable manufactory is that commonly called tin plates. The cheapness of iron and coal causes the tin of Cornwall to be sent here, and spread over those iron plates, which are afterwards dispersed all over the world.

In like manner, the copper ore from Cornwall, from North Wales, and from Ireland, is attracted to Glamorganshire by the cheapness of coal; and it is smelted in works upon a most extensive scale, in the vicinity of Aberavon, Neath, and Swansea, whence it is forwarded by water-carriage to the places where it receives its final appropriations to the several purposes for which it is wanted. There are some extensive manufactories of earthen ware, which are increasing in their operations; and small concerns adapted for making soap, salt, and woollen cloths.

The most considerable exported production from this county is coals from the ports of Swansea and Neath. At the former of these ports, the facility of loading vessels is so great, that ships of three hundred tons burden enter with one tide, are loaded and enabled to sail sometimes the next, but usually the next tide but one. The quantity annually exported amounts to about 450,000 tons, and more might be shipped, but for some superior privileges in the city of Bristol, which favour the coal-mines of Monmouthshire and Gloucestershire.

The rivers of Glamorganshire are, 1*st*, The Taf or Tave, over which is the celebrated bridge of one arch, supposed to be the largest in the world, being one hundred and forty feet in the span, planned and executed by an untaught country mason, a native of the county; 2*d*, the Elay, a stream of short course, near Llantrissent; 3*d*, the Ogmore, crossing the county, and entering the sea near Bridgend; 4*th*, the Nedd or Neath, passing from Brecknockshire, through most romantic valleys, by Neath, to the sea at Britton Ferry; and, 5*th*, the Tawy, which discharges itself into Swansea Bay.

As these rivers are scarcely navigable, and the two which are so, but for a short distance, canals have been constructed for the conveyance of the heavy productions of the county, and have produced a wonderful effect both on its wealth and population. These are the Cardiff Canal, which affords water-carriage from Myrthr-Tydvil to Penarth Bay; the Neath Canal, which traverses the county from south to north; and the Swansea Canal, which runs to the north till it reaches Brecknockshire. The number of railroads communicating between the iron-works and coal-mines and the canals are too numerous to admit of being enumerated, and have proved very beneficial undertakings both to the constructors and to the public.

The peasantry of this county generally use the Welsh language, and either cannot or will not speak English. In the towns, however, the latter is very commonly spoken, and in the churches the service is occasionally conducted in it. There is, however, a portion of the county, to the south of the mountains round Oxwich Bay, where the Welsh language is quite unknown, whilst, on the opposite side of the same mountains, the inhabitants are unacquainted with English.

Glamorganshire returns to the House of Commons two members for the county, and one for the newly created rough of Myrthr-Tydvil, and also one for the old united roughs of Cardiff, Cowbridge, and Llantrissent. The pulation returns of the four decennial censuses give the habitants in 1801, 71,525; in 1811, 85,067; in 1821, 1,737; and in 1831, 126.200.

The county town is Cardiff, and it is the chief place r shipping the iron of Myrthr-Tydvil. Its pier is now cessible for ships of two hundred tons, but some imovements are in progress which will enlarge the harbour, d adapt it for the reception of vessels of a greater draught water than can now reach it. The chief towns, and eir population, are as follow :—Myrthr-Tydvil, 22,083; vansea, 13,256; Cardiff, 6187; Neath, 4034; Llansamlet, 87; and Llantrissent, 2789. Landaff, though a city and e seat of a bishop, has only 1299 inhabitants.

As the picturesque beauty of many parts of the county very great, it has ever been the favourite resort of many milies of respectability. That it was so in ancient times, e number of ruins of ancient castles clearly evince; and w parts of the island, excepting the immediate vicinity the metropolis, have so many gentlemen's seats within em. The principal of these are, Gnoll Castle, the seat the Mackworths, now Mr Grant; Cardiff Castle, Maris of Bute; Dunraven, Thomas Wyndham, Esq.; nlline Castle, Lord Vernon; Margram, Mr Talbot; assmont, Sir John Morris; Southall, John Lucas, Esq.; llyhir, Sir Gabriel Powell; Penllergaer, John Llewelyn, q.; Penrice Castle, R. M. Talbot, Esq.; Woodlands, eneral Ward; and Penderi, Thomas Morgan, Esq.; with ny others.

(See Rees's *South Wales;* Malkin's *Scenery of South ales; Parliamentary Returns.*)

GLAMOUR, or **GLAMER**, an old term of popular surstition in Scotland, denoting a kind of magical mist, lieved to be raised by sorcerers, and which deluded the ectators with visions of things that had no real existce, altered the appearance of those which really did ist, and produced other effects equally wonderful. The stern nations have a similar superstition, as we learn om the Arabian Nights Entertainments, and other works oriental fiction.
